Brocade(config)#access-list 101 permit ip any any mirror
```

3. Apply the ACL-based inbound clause to the monitor port.

```
Brocade(config)#interface e 1/1/5
Brocade(config-if-e1000-1/1/5)#ip access-group 101 in
```

4. Create the ACL mirror port.

```
Brocade(config-if-e1000-1/1/5)#acl-mirror-port ethernet 1/1/2
```

To display ACL mirror settings, enter the **show access-list all** command.

```
Brocade#show access-list all
Extended IP access list 101
permit ip any any mirror
```

ACL-based inbound mirror clauses for FastIron X Series devices

The **mirror** parameter in an ACL clause causes the system to direct traffic that meets the clause to be sent to a mirror port. Consider the following example.

```
Brocade(config)#access-list 101 permit ip any any mirror
```

The **mirror** parameter directs selected traffic to the mirrored port. Traffic mirroring is only supported on Layer 3 ACLs for FastIron X Series devices.

You can select traffic to be mirrored using a **permit** or **deny** clause on ports on the following interface modules:

- SX-FI-24GPP
- SX-FI-24HF
- SX-FI-2XG
- SX-FI-8XG

On all other interface modules, you can select traffic to be mirrored using only a **permit** clause.

Destination mirror port

You can specify physical ports or a trunk to mirror traffic. If you complete the rest of the configuration but do not specify a destination mirror port, the port-mirroring ACL is non-operational. This can be useful if you want to be able to mirror traffic by a set criteria on demand. With this configuration, you configure a destination mirror port whenever you want the port-mirroring ACL to become operational.

The following sections describe how to specify a destination port for a port or a trunk, as well as the special considerations required when mirroring traffic from a virtual interface.

Specifying the destination mirror port for physical ports

When you want traffic that has been selected by ACL-based inbound mirroring to be mirrored, you must configure a destination mirror port. This configuration is performed at the interface configuration level of the port with the traffic you are mirroring. The destination port must be the same for all ports in a port region as described in [“Ports from a port region must be mirrored to the same destination mirror port”](#) on page 933.

In the following example, ACL mirroring traffic from port 1/1 is mirrored to port 1/3.

```
Brocade(config)#interface ethernet 1/1
Brocade(config-if-e1000-1/1)#ACL-mirror-port ethernet 1/3
```

Syntax: [no] **ACL-mirror-port ethernet <port>**

The **<port>** variable specifies the mirror port to which the monitored port traffic is copied.

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Ports from a port region must be mirrored to the same destination mirror port

Port regions, as described in “[About port regions](#)” on page 556, are important when defining a destination mirror port. This is because all traffic mirrored from any single port in a port region is mirrored to the same destination mirror port as traffic mirrored from any other port in the same port region. For example, ports 1/1 to 1/12 are in the same port region. If you configure ports 1/1 and 1/2 to mirror their traffic, they should use the same destination mirror port as shown in the following configuration.

```
Brocade(config)#interface ethernet 1/1
Brocade(config-if-e10000-1/1)#ACL-mirror-port ethernet 2/3
Brocade(config)#interface ethernet 1/2
Brocade(config-if-e10000-1/2)#ACL-mirror-port ethernet 2/3
```

If ports within the same port region are mirrored to different destination ports, the configuration is disallowed, and an error message is generated, as shown in the following example.

```
Brocade(config)#interface ethernet 1/1
Brocade(config-if-e10000-1/1)#ACL-mirror-port ethernet 4/3
Brocade(config)#interface ethernet 1/2
Brocade(config-if-e10000-1/2)#ACL-mirror-port ethernet 4/7
Error - Inbound Mirror port 4/3 already configured for port region 1/1 - 1/12
```

When a destination port is configured for any port within a port region, traffic from any ACL with a mirroring clause assigned to any port in that port region is mirrored to that destination port. This will occur even if a destination port is not explicitly configured for the port with the ACL configured. In the following example, an ACL with a mirroring clause (101) is applied to a port (1/1). Another port in the same region (1/3) has a destination port set (4/3). In this example, traffic generated from operation of ACL 101 is mirrored to port 4/3 even though a destination port has not explicitly been defined for traffic from port 1/1.

```
Brocade(config)#interface ethernet 1/1
Brocade(config-if-e10000-1/1)#ip access-group 101 in
Brocade(config)#interface ethernet 1/3
Brocade(config-if-e10000-1/3)#ACL-mirror-port ethernet 4/3
```

NOTE

If a destination mirror port is not configured for any ports within the port region where the port-mirroring ACL is configured, the ACL does not mirror the traffic but the ACL is applied to traffic on the port.

Specifying the destination mirror port for trunk ports

You can mirror the traffic that has been selected by ACL-based inbound mirroring from a trunk by configuring a destination port for the primary port within the trunk configuration, as shown in the following example.

```
Brocade(config)#trunk ethernet 1/1 to 1/4
Brocade(config)#interface ethernet 1/1
Brocade(config-if-e10000-1/1)#ACL-mirror-port ethernet 1/8
```

Using this configuration, all trunk traffic is mirrored to port 1/8.

Limitations when configuring ACL-based mirroring with trunks

The **config-trunk-ind** command, as described in [“Disabling or re-enabling a trunk port”](#) on page 712, cannot operate with ACL-based mirroring:

- If a trunk is configured with the **config-trunk-ind** command, ACL-based mirroring will not be allowed.
- If the **config-trunk-ind** command is added to a trunk, any ports that are configured for ACL-based mirroring will have monitoring removed and the following message is displayed.

Trunk port monitoring, if any, has been removed.

If an individual port is configured for ACL-based mirroring, you cannot add it to a trunk. If you try to add a port that is configured for ACL-based mirroring to a trunk, the following message appears.

Note - ACL-mirror-port configuration is removed from port 2 in new trunk.

NOTE

If you want to add a port configured for ACL-based mirroring to a trunk, you must first remove the **ACL-mirror-port** command from the port configuration. You can then add the port to a trunk that can then be configured for ACL-based trunk mirroring.

Behavior of ACL-based mirroring when deleting trunks

If you delete a trunk that has ACL-based mirroring configured, the ACL-based mirroring configuration is configured on the individual ports that made up the trunk.

For example, if a trunk is configured as shown in the following example and is then deleted from the configuration as shown, each of the ports that previously was contained in the trunk is configured for ACL-based mirroring.

```
Brocade(config)#trunk ethernet 4/1 to 4/2
Brocade(config)#trunk deploy
Brocade(config)#interface ethernet 4/1
Brocade(config-if-e10000)#ACL-mirror-port ethernet 5/3
```

To delete the trunk, enter the following command.

```
Brocade(config)#no trunk ethernet 4/1 to 4/2
```

The following configuration for ACL-based mirroring on ports 4/1 and 4/2 results from the trunk being deleted.

```
interface ethernet 4/1
  ACL-mirror-port ethernet 5/3
interface ethernet 4/2
  ACL-mirror-port ethernet 5/3
```

Configuring ACL-based mirroring for ACLs bound to virtual interfaces

For configurations that have an ACL configured for ACL-based mirroring bound to a virtual interface, you must use the **ACL-mirror-port** command on a physical port that is a member of the same VLAN as the virtual interface. Additionally, only traffic that arrives at ports that belong to the same port group as the physical port where the **ACL-mirror-port** command has been used is mirrored. This follows the same rules described in [“Ports from a port region must be mirrored to the same destination mirror port”](#) on page 933.

For example, in the following configuration, ports 4/1, 4/2, and 5/3 are in VLAN 10 with ve 10. Ports 4/1 and 4/2 belong to the same port group, while port 5/3 belongs to another port group.

```
Brocade(config)#vlan 10
Brocade(config-vlan-10)#tagged ethernet 4/1 to 4/2
Brocade(config-vlan-10)#tagged ethernet 5/3
Brocade(config-vlan-10)#router-interface ve 10

Brocade(config)#interface ethernet 4/1
Brocade(config-if-e10000-4/1)#ACL-mirror-port ethernet 5/1
Brocade(config)#interface ve 10
Brocade(config-vif-10)#ip address 10.10.10.254/24
Brocade(config-vif-10)#ip access-group 102 in
Brocade(config)#access-list 102 permit ip any any mirror
```

In this configuration, the **ACL-mirror-port** command is applied to port 4/1, which is a member of ve 10. Because of this, ACL-based mirroring will only apply to VLAN 10 traffic that arrives on ports 4/1 and 4/2. It will not apply to VLAN 10 traffic that arrives on port 5/3 because that port belongs to a port group different from ports 4/1 and 4/2. This is because if you apply ACL-based mirroring on an entire VE, and enable mirroring in only one port region, traffic that is in the same VE but on a port in a different port region will not be mirrored.

To make the configuration apply ACL-based mirroring to VLAN 10 traffic arriving on port 5/3, you must add the following commands to the configuration.

```
Brocade(config)#interface ethernet 5/3
Brocade(config-if-e10000-5/3)#ACL-mirror-port ethernet 5/1
```

If a port is in both mirrored and non-mirrored VLANs, only traffic on the port from the mirrored VLAN is mirrored. For example, the following configuration adds VLAN 20 to the previous configuration. In this example, ports 4/1 and 4/2 are in both VLAN 10 and VLAN 20. ACL-based mirroring is only applied to VLAN 10. Consequently, traffic that is on ports 4/1 and 4/2 that belongs to VLAN 20 will not be mirrored.

```
Brocade(config)#vlan 10
Brocade(config-vlan-10)#tagged ethernet 4/1 to 4/2
Brocade(config-vlan-10)#tagged ethernet 5/3
Brocade(config-vlan-10)#router-interface ve 10

Brocade(config)#vlan 20
Brocade(config-vlan-20)#tagged ethernet 4/1 to 4/2

Brocade(config)#interface ethernet 4/1
Brocade(config-if-e10000-4/1)#ACL-mirror-port ethernet 5/1
Brocade(config)#interface ve 10
Brocade(config-vif-10)#ip address 10.10.10.254/24
Brocade(config-vif-10)#ip access-group 102 in
Brocade(config)#access-list 102 permit ip any any mirror
```

MAC address filter-based mirroring

NOTE

The MAC address filter-based mirroring feature is not supported on FastIron X Series devices.

This feature allows traffic entering an ingress port to be monitored from a mirror port connected to a data analyzer, based on specific source and destination MAC addresses. This feature supports mirroring of inbound traffic only. Outbound mirroring is not supported.

MAC-filter-based mirroring allows a user to specify a particular stream of data for mirroring using a filter. This eliminates the need to analyze all incoming data to the monitored port. To configure MAC-filter-based mirroring, the user must perform three steps:

1. Define a mirror port
2. Create a MAC address filter with a mirroring clause
3. Apply the MAC address filter to an interface

Configuring MAC address filter-based mirroring

Complete the following steps to configure MAC address filter-based mirroring.

1. Defining a mirror port

To activate mirroring on a port, use the **mirror** command in global configuration mode.

```
Brocade(config)#mirror e 0/1/14
```

Configuration notes for defining a mirror port

- If there is no input mirror port configured, MAC-filter based mirroring does not take effect. It remains in the configuration, but is not activated.
- FWS devices support one ingress mirror and one egress mirror per system. These ports are shared by all mirroring features: port-based mirroring, VLAN-based mirroring, ACL-based mirroring and MAC-based mirroring.
- MAC-filter-based mirroring can be enabled on a port at the same time as either port-based mirroring or VLAN-based mirroring. When port-based mirroring and MAC-filter-based mirroring are enabled on a port at the same time, the preference order is port-based mirroring followed by MAC-based filtering. When VLAN-based mirroring and MAC-filter-based mirroring are enabled on a port at the same time, the preference order is VLAN-based mirroring and MAC-filter-based mirroring.

NOTE

Port-based mirroring and VLAN-based mirroring can not be enabled on a port at the same time.

2. Creating a MAC address filter with a mirroring clause

The **mirror** keyword is added to MAC address filter clauses to direct desired traffic to the mirror port. In the following example, the MAC address filter directs traffic to a mirror port.

```
Brocade(config)#mac filter 1 permit 0000.1111.2222 ffff.ffff.ffff 0000.2222.3333
fff.fff.fff mirror
```

In this example, any flow matching the source address (SA) 0000.1111.2222 and the destination address (DA) 0000.2222.3333 is mirrored. Other flows are not mirrored.

3. Applying the MAC address filter to an interface

Apply the MAC address filter to an interface using the **mac-filter-group** command.

```
Brocade(config)#interface ethernet 0/1/1
Brocade(config-if-e10000-0/1/1)#mac filter-group 1
```

4. Configuring the monitor port to use the mirror port

```
Brocade(config)#interface ethernet 0/1/5
Brocade(config-if-e10000-0/1/5)#acl-mirror-port ethernet 0/1/14
```

VLAN-based mirroring

NOTE

VLAN-based mirroring is supported on FastIron X Series devices equipped with third generation or later modules. Refer to [“VLAN-based mirroring on FastIron X Series devices”](#) on page 939.

The VLAN-based mirroring feature allows users to monitor all incoming traffic in one or more VLANs by sending a mirror image of that traffic to a configured mirror port. This feature meets the requirements of CALEA (Communications Assistance for Law Enforcement Act of 1994).

Configuring VLAN-based mirroring

Configure VLAN-based mirroring using the **monitor ethernet** command in VLAN configuration mode. For example, to enable mirroring on VLANs 10 and 20, to mirror port e 1/1/21, enter the following commands.

```
Brocade(config)#mirror-port ethernet 1/1/21 input
Brocade(config)#vlan 10
Brocade(config-VLAN-10)#monitor ethernet 1/1/21
Brocade(config-VLAN-10)#exit
Brocade(config)#vlan 20
Brocade(config-VLAN-20)#monitor ethernet 1/1/21
Brocade(config-VLAN-20)#end
```

Syntax: [no] monitor ethernet <port>

NOTE

For FCX devices, because it is possible to have multiple mirror ports, monitor ports must specify which mirror port they are monitoring.

To disable mirroring on VLAN 20, enter the following commands.

```
Brocade(config)#vlan 20
Brocade(config-VLAN-20)#no monitor ethernet 1/1/21
Brocade(config-VLAN-20)#end
```

Displaying VLAN-based mirroring status

The **show vlan** command displays the VLAN-based mirroring status.

VLAN-based mirroring

```
Brocade#show vlan
Total PORT-VLAN entries: 4
Maximum PORT-VLAN entries: 4060

Legend: [Stk=Stack-Unit, S=Slot]

PORT-VLAN 1, Name DEFAULT-VLAN, Priority level0, Spanning tree On
Untagged Ports: (Stk0/S1)  3  4  5  6  7  8  9 10 11 12 13 14
Untagged Ports: (Stk0/S1) 15 16 17 18 19 20 21 22 23 24 25 26
Untagged Ports: (Stk0/S1) 27 28 29 30 31 32 33 34 35 36 37 38
Untagged Ports: (Stk0/S1) 39 40 41 42 43 44 45 46 47 48
Untagged Ports: (Stk0/S2)  1  2
Tagged Ports: None
Uplink Ports: None
DualMode Ports: None
Mac-Vlan Ports: None
Monitoring: Disabled
PORT-VLAN 10, Name [None], Priority level0, Spanning tree On
Untagged Ports: (Stk0/S1)  1
Tagged Ports: None
Uplink Ports: None
DualMode Ports: None
Mac-Vlan Ports: None
Monitoring: Enabled
PORT-VLAN 20, Name [None], Priority level0, Spanning tree On
Untagged Ports: (Stk0/S1)  2
Tagged Ports: None
Uplink Ports: None
DualMode Ports: None
Mac-Vlan Ports: None
Monitoring: Disabled
```

Configuration notes for VLAN-based mirroring

The following guidelines apply to VLAN-based mirroring configurations:

- A VLAN must have at least one port member configured before monitoring can be configured.
- Multiple VLANs can have monitoring enabled at the same time, and the maximum number of monitor-configured VLANs is 8.
- FWS devices support one ingress and one egress mirror per system. These mirror ports are shared by all mirroring features; port-based mirroring, VLAN-based mirroring, ACL-based mirroring, and MAC-filter-based mirroring.
- The mirror port is subject to the same scheduling and bandwidth management as the other ports in the system. If the amount of traffic being sent to the mirror port exceeds the available bandwidth, some of that traffic may be dropped.
- All incoming traffic (tagged and untagged) in the VLAN is mirrored. mirroring is “as-is”, and is not affected by the configuration of the mirror port itself. Incoming tagged traffic is sent out tagged and incoming untagged traffic is sent out untagged, regardless of which VLANs the mirror port belongs to, and whether the mirror port is tagged or untagged.
- VLAN-based mirroring is supported on Layer 2 and Layer 3 images.

VLAN-based mirroring on FastIron X Series devices

With the new FastIron X Series of modules, the sFlow processing has been separated from the packet mirroring functionality. This allows for support of VLAN-based mirroring on the FastIron X Series devices. The packet processor on the FastIron X Series of modules also allows for egress VLAN-based mirroring. In order for VLAN-based monitoring to function, the FastIron X Series must have only the following SX modules installed.

The following interface modules are new to the FastIron X Series:

- SX-FI-24GPP
- SX-FI-24HF
- SX-FI-2XG
- SX-FI-8XG
- SX-FI48GPP

NOTE

Egress VLAN-based mirroring is not currently supported on the stacking platforms.

The FastIron X Series of modules are capable of monitoring 4096 VLANs. In a chassis environment, this introduces restrictions to the number of ports that can be configured as mirror ports. Because a single VLAN can contain 384 untagged ports (24 per slot) if that VLAN is configured for monitoring, every device must have an identical number of corresponding analyzer ports. However, the egress mirror-port and ingress mirror-port do not have to be the same. You can use two separate ports.

This introduces restrictions on port-based mirroring coexisting with VLAN-based mirroring. Port-based mirroring allows for multiple ports to be configured as mirror-ports. However, once a particular port belonging to a particular device is configured for monitoring to a specific mirror-port, no other mirror-port can be used to monitor any other port on that device. This restriction has been extended to VLAN-based mirroring, with one caveat: only one mirror-port in either direction at a time can exist within the system. Refer to [“About port regions”](#) on page 556 for a list of valid port ranges on these devices.

Restrictions and capabilities of VLAN-based mirroring

The following is a list of restrictions and capabilities:

- Only the modules that support VLAN-based mirroring should be installed.
- There can be only one input or output mirror-port configured in the system at a time.
- The amount of traffic mirrored is limited by the bandwidth of the mirror-port.
- The maximum amount of egress traffic that can be mirrored is further limited by the bandwidth of the loopback port, which is 10 Gbps.
- The monitored VLAN must be created in hardware.
- An ingress or egress mirror-port must be configured when monitoring the ingress or egress VLAN traffic.
- A maximum of 4096 VLANs can be monitored at a time.
- A VLAN can be monitored for ingress and egress traffic concurrently.
- Port mirroring can be configured concurrently with VLAN-based mirroring, but only one mirror-port can be used for both.

- sFlow can be enabled concurrently with VLAN-based mirroring and port mirroring.
- VLAN-based mirroring is supported on the default VLAN. If the default VLAN is changed dynamically, the configuration is not lost.
- VLAN-based mirroring on VLAN groups is not supported, but it is supported on topology groups.
- In the case of enabling VLAN-based monitoring on the interface modules in an MCT-enabled chassis, the VLAN configuration is not synced across the cluster. Each chassis in the cluster is configured independently for VLAN configuration.

One of the concerns about VLAN-based mirroring is the effects of ingress and egress ACLs, as well as rate shaping and rate limiting, on mirrored packets:

- Ingress VLAN-based mirroring: Any packets that are coming in from the network on the VLAN should be mirrored out. Any ingress ACL actions or rate limiting actions do not take precedence in this case.
- Egress VLAN-based mirroring: Any packets that are sent out onto the network are not affected by egress ACLs or rate shaping.

Refer to Table 160 for a summary of the effects of ACLs and rate limiting.

TABLE 160 ACL and rate limiting effects

ACL profile	Ingress result	Egress result
Ingress ACL on port	Packets ingress mirrored at expected (sent) rate	Packets egress mirrored at expected (sent) rate
Egress ACL on port	Packets ingress mirrored at expected (sent) rate	Packets egress mirrored at expected (sent) rate
Ingress rate limiting on port	Packets ingress mirrored at expected (sent) rate	Packets egress mirrored at the limited rate
Egress rate shaping on port	Packets ingress mirrored at expected (sent) rate	Packets egress mirrored at expected (sent) rate

Tagged versus untagged ports in VLANs

Table 161 describes how VLAN-based mirroring coexists with port mirroring, assuming a VLAN consisting of one ingress and one egress port.

TABLE 161 VLAN-based mirroring and port mirroring effects

Packets sent	VLAN-based mirroring direction	Which port in VLAN is monitored	Ingress mirror traffic count expectation	Egress mirror traffic count expectation
10000	Ingress	Ingress	~10000	~0
10000	Egress	Egress	~0	~20000
10000	Ingress	Egress	~10000	~10000
10000	Egress	Ingress	~10000	~10000

Table 161 can be summarized into the following two rules, assuming that VLAN-based mirroring and port mirroring are operating concurrently.

- If the VLAN is ingress monitored, and ports belonging to the VLAN are also ingress monitored, the ingress traffic is only mirrored once and there are no duplicated mirrored packets.

- If the VLAN is egress monitored and ports belonging to the VLAN are also egress monitored, the egress traffic is mirrored for each egress port, as well as the VLAN, resulting in several duplicated mirrored packets. The count of duplicate packets is computed as (1 + Number of egress mirrored ports in the VLAN) * Number of egress packets.

In addition to the previously mentioned rules, the behavior of VLAN-based mirroring is affected by the tag type of the ports belonging to that VLAN, as shown in [Table 162](#).

TABLE 162 VLAN-based mirroring behavior: Tagged versus untagged ports

Ingress tag type	Egress tag type	VLAN-based mirroring direction	Mirrored traffic tag type
Untagged	Untagged	Ingress	Untagged
Untagged	Untagged	Egress	Tagged
Untagged	Tagged	Ingress	Untagged
Untagged	Tagged	Egress	Tagged
Tagged	Untagged	Ingress	Tagged
Tagged	Untagged	Egress	Tagged
Tagged	Tagged	Ingress	Tagged
Tagged	Tagged	Egress	Tagged

As illustrated in [Table 162](#), regardless of the egress port tag type, if a VLAN is egress mirrored, the mirrored traffic is always tagged. This functionality is built into the hardware and is the expected behavior, as the tag acts as an identifier for monitored traffic on the mirror-port (in case the mirror-port belongs to some other VLAN).

Configuring VLAN-based mirroring on FastIron X Series devices

Configure VLAN-based mirroring using the **monitor ethernet** command in VLAN configuration mode. For example, to enable incoming mirroring on VLANs 10 and 20, to mirror port e 6/24, enter the following commands.

```
Brocade(config)#mirror-port ethernet 6/24
Brocade(config)#vlan 10
Brocade(config-VLAN-10)#monitor ethernet 6/24 input
Brocade(config-VLAN-10)#exit
Brocade(config)#vlan 20
Brocade(config-VLAN-20)#monitor ethernet 6/24 input
Brocade(config-VLAN-20)#end
```

For example, to enable outgoing mirroring on VLANs 10 and 20, to mirror port e 6/24, enter the following commands.

```
Brocade(config)#mirror-port ethernet 6/24
Brocade(config)#vlan 10
Brocade(config-VLAN-10)#monitor ethernet 6/24 output
Brocade(config-VLAN-10)#exit
Brocade(config)#vlan 20
Brocade(config-VLAN-20)#monitor ethernet 6/24 output
Brocade(config-VLAN-20)#end
```

For example, to enable bidirectional mirroring on VLANs 10 and 20, to mirror port e 6/24, enter the following commands.

```
Brocade(config)#mirror-port ethernet 6/24
```

VLAN-based mirroring

```
Brocade(config)#vlan 10
Brocade(config-VLAN-10)#monitor ethernet 6/24 both
Brocade(config-VLAN-10)#exit
Brocade(config)#vlan 20
Brocade(config-VLAN-20)#monitor ethernet 6/24 both
Brocade(config-VLAN-20)#end
```

To disable mirroring on VLAN 20, enter the following commands.

```
Brocade(config)#vlan 20
Brocade(config-VLAN-20)#no monitor ethernet 6/24
Brocade(config-VLAN-20)#end
```

Displaying VLAN-based mirroring status

The **show vlan** command displays the VLAN-based mirroring status.

```
Brocade(config-if-e1000-5/2)#show vlan 10
```

```
Total PORT-VLAN entries: 2
```

```
Maximum PORT-VLAN entries: 64
```

```
Legend: [Stk=Stack-Id, S=Slot]
```

```
PORT-VLAN 10, Name To-SXR1600, Priority level0, Spanning tree Off
```

```
Untagged Ports: (S5) 2 4
```

```
Tagged Ports: None
```

```
Uplink Ports: None
```

```
DualMode Ports: None
```

```
RX Monitoring: Disabled
```

```
TX Monitoring: Enabled
```

Syntax: [no] monitor ethernet <port> [input | output | both]

IP Configuration

Table 163 lists the individual Brocade FastIron switches and the IP features they support. These features are supported with the base Layer 3, edge Layer 3 and full Layer 3 software image, except where explicitly noted.

TABLE 163 Supported IP features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
BootP/DHCP relay	Yes	Yes	Yes	Yes	ICX 6450 only
Specifying which IP address will be included in a DHCP/BootP reply packet	Yes	No	Yes	Yes	Yes
DHCP Server	Yes	Yes	Yes	Yes	Yes
DHCP Client-Based Auto-Configuration	Yes	Yes	Yes	Yes	Yes
DHCP Client-Based Flash image Auto-update	Yes	Yes	Yes	Yes	Yes
DHCP assist	Yes	Yes	Yes	Yes	Yes
Equal Cost Multi Path (ECMP) load sharing	Yes	Yes	Yes	Yes	ICX 6450 only
IP helper	Yes	Yes	Yes	Yes	ICX 6450 only
Single source address for the following packet types: <ul style="list-style-type: none"> • Telnet • TFTP • Syslog • SNTP • TACACS/TACACS+ • RADIUS • SSH • SNMP 	Yes	No	No	No	No
IPv4 point-to-point GRE IP tunnels	Yes (IPv6 devices only)	No	Yes	Yes	No
Routes in hardware maximum: <ul style="list-style-type: none"> • FESX6 – Up to 256K routes • FSX – Up to 512K routes • FCX – Up to 16K routes • FWS – Up to 1020 routes • ICX 6450 - Up to 12,000 routes 	Yes	Yes	Yes	Yes	ICX 6450 only

TABLE 163 Supported IP features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
Routing for directly connected IP subnets	Yes	Yes	Yes	Yes	ICX 6450 only
Virtual Interfaces: • Up to 512 virtual interfaces	Yes	Yes	Yes	Yes	ICX 6450 only, up to 255
31-bit subnet mask on point-to-point networks	Yes on devices running full Layer 3 image	No	Yes on devices running full Layer 3 image	Yes on devices running full Layer 3 image	No
Address Resolution Protocol (ARP)	Yes	Yes	Yes	Yes	ICX 6450 only
Reverse Address Resolution Protocol (RARP)	Yes	Yes	Yes	Yes	ICX 6450 only
IP follow	Yes	Yes	Yes	Yes	ICX 6450 only
Proxy ARP	Yes	Yes	Yes	Yes	ICX 6450 only
Local proxy ARP	Yes	Yes	Yes	Yes	ICX 6450 only
Jumbo frames • Up to 10,240 bytes, or • Up to 10,232 bytes in an IronStack	Yes	Yes	Yes	Yes	Yes
IP MTU (individual port setting)	Yes	No	Yes	Yes	ICX 6450 only
Path MTU discovery	Yes	No	Yes	Yes	No
ICMP Router Discovery Protocol (IRDP)	Yes	Yes	Yes	Yes	ICX 6450 only
Domain Name Server (DNS) resolver	Yes	Yes	Yes	Yes	Yes
IP checksum check disable	Yes	No	No	No	No

NOTE

References to chassis-based Layer 3 Switches apply to the FSX 800 and FSX 1600.

NOTE

The terms Layer 3 Switch and router are used interchangeably in this chapter and mean the same.

Basic IP configuration

IP is enabled by default. Basic configuration consists of adding IP addresses for Layer 3 Switches, enabling a route exchange protocol, such as the Routing Information Protocol (RIP).

If you are configuring a Layer 3 Switch, refer to [“Configuring IP addresses”](#) on page 964 to add IP addresses, then enable and configure the route exchange protocols, as described in other chapters of this guide.

If you are configuring a Layer 2 Switch, refer to [“Configuring the management IP address and specifying the default gateway”](#) on page 1037 to add an IP address for management access through the network and to specify the default gateway.

The rest of this chapter describes IP and how to configure it in more detail. Use the information in this chapter if you need to change some of the IP parameters from their default values or you want to view configuration information or statistics.

IP configuration overview

Brocade Layer 2 Switches and Layer 3 Switches support Internet Protocol version 4 (IPv4) and IPv6. IP support on Brocade Layer 2 Switches consists of basic services to support management access and access to a default gateway.

Edge Layer 3 support

NOTE

Edge Layer 3 images are supported on FWS-EPREM and FWSG-EPREM models.

IP support on Brocade edge Layer 3 Switches includes support for all of the base Layer 3 features, in addition to the following:

- OSPF V2 (IPv4)
- Full RIP V1 and V2
- Route-only support (Global configuration level only)
- Route redistribution
- 1020 routes in hardware maximum
- VRRP-E

Full Layer 3 support

NOTE

Full Layer 3 images are supported on FastIron X Series -PREM and Brocade FCX Series devices only.

IP support on Brocade full Layer 3 Switches includes all of the following, in addition to a highly configurable implementation of basic IP services including Address Resolution Protocol (ARP), ICMP Router Discovery Protocol (IRDP), and Reverse ARP (RARP):

- Route exchange protocols:
 - Routing Information Protocol (RIP)
 - Open Shortest Path First (OSPF)
 - Border Gateway Protocol version 4 (BGP4)

- Multicast protocols:
 - Internet Group Membership Protocol (IGMP)
 - Protocol Independent Multicast Dense (PIM-DM)
 - Protocol Independent Multicast Sparse (PIM-SM)
 - Distance Vector Multicast Routing Protocol (DVMRP)
- Router redundancy protocols:
 - Virtual Router Redundancy Protocol Extended (VRRP-E)
 - Virtual Router Redundancy Protocol (VRRP)

IP interfaces

NOTE

This section describes IPv4 addresses. For information about IPv6 addresses on FastIron X Series devices, refer to [“IPv6 addressing overview”](#) on page 355. For information about IPv6 addresses on all other FastIron devices, refer to [“IPv6 addressing”](#) on page 412.

Brocade Layer 3 Switches and Layer 2 Switches allow you to configure IP addresses. On Layer 3 Switches, IP addresses are associated with individual interfaces. On Layer 2 Switches, a single IP address serves as the management access address for the entire device.

All Brocade Layer 3 Switches and Layer 2 Switches support configuration and display of IP addresses in classical subnet format (for example: 192.168.1.1 255.255.255.0) and Classless Interdomain Routing (CIDR) format (for example: 192.168.1.1/24). You can use either format when configuring IP address information. IP addresses are displayed in classical subnet format by default but you can change the display format to CIDR. Refer to [“Changing the network mask display to prefix format”](#) on page 1065.

Layer 3 Switches

Brocade Layer 3 Switches allow you to configure IP addresses on the following types of interfaces:

- Ethernet ports
- Virtual routing interfaces (used by VLANs to route among one another)
- Loopback interfaces

Each IP address on a Layer 3 Switch must be in a different subnet. You can have only one interface that is in a given subnet. For example, you can configure IP addresses 192.168.1.1/24 and 192.168.2.1/24 on the same Layer 3 Switch, but you cannot configure 192.168.1.1/24 and 192.168.1.2/24 on the same Layer 3 Switch.

You can configure multiple IP addresses on the same interface.

The number of IP addresses you can configure on an individual interface depends on the Layer 3 Switch model. To display the maximum number of IP addresses and other system parameters you can configure on a Layer 3 Switch, refer to [“Displaying and modifying system parameter default settings”](#) on page 578.

You can use any of the IP addresses you configure on the Layer 3 Switch for Telnet, Web management, or SNMP access.

Layer 2 Switches

You can configure an IP address on a Brocade Layer 2 Switch for management access to the Layer 2 Switch. An IP address is required for Telnet access, Web management access, and SNMP access.

You also can specify the default gateway for forwarding traffic to other subnets.

IP packet flow through a Layer 3 Switch

Figure 110 shows how an IP packet moves through a Brocade Layer 3 Switch.

FIGURE 110 IP Packet flow through a Brocade Layer 3 Switch

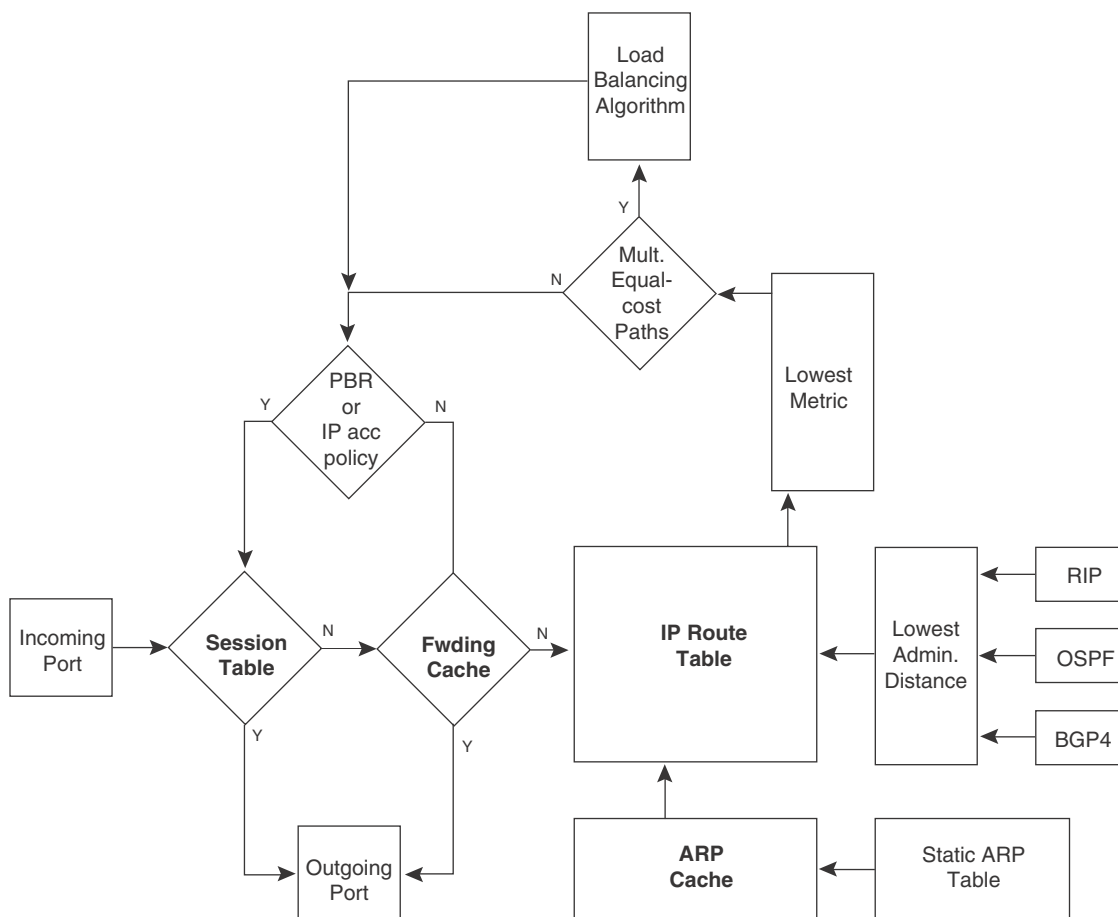

Figure 110 shows the following packet flow:

1. When the Layer 3 Switch receives an IP packet, the Layer 3 Switch checks for filters on the receiving interface.¹ If a deny filter on the interface denies the packet, the Layer 3 Switch discards the packet and performs no further processing, except generating a Syslog entry and SNMP message, if logging is enabled for the filter.
2. If the packet is not denied at the incoming interface, the Layer 3 Switch looks in the session table for an entry that has the same source IP address and TCP or UDP port as the packet. If the session table contains a matching entry, the Layer 3 Switch immediately forwards the packet, by addressing it to the destination IP address and TCP or UDP port listed in the session table entry and sending the packet to a queue on the outgoing ports listed in the session table. The Layer 3 Switch selects the queue based on the Quality of Service (QoS) level associated with the session table entry.
3. If the session table does not contain an entry that matches the packet source address and TCP or UDP port, the Layer 3 Switch looks in the IP forwarding cache for an entry that matches the packet destination IP address. If the forwarding cache contains a matching entry, the Layer 3 Switch forwards the packet to the IP address in the entry. The Layer 3 Switch sends the packet to a queue on the outgoing ports listed in the forwarding cache. The Layer 3 Switch selects the queue based on the Quality of Service (QoS) level associated with the forwarding cache entry.
4. If the IP forwarding cache does not have an entry for the packet, the Layer 3 Switch checks the IP route table for a route to the packet destination. If the IP route table has a route, the Layer 3 Switch makes an entry in the session table or the forwarding cache, and sends the route to a queue on the outgoing ports:
 - If the running-config contains an IP access policy for the packet, the software makes an entry in the session table. The Layer 3 Switch uses the new session table entry to forward subsequent packets from the same source to the same destination.
 - If the running-config does not contain an IP access policy for the packet, the software creates a new entry in the forwarding cache. The Layer 3 Switch uses the new cache entry to forward subsequent packets to the same destination.

The following sections describe the IP tables and caches:

- ARP cache and static ARP table
- IP route table
- IP forwarding cache
- Layer 4 session table

The software enables you to display these tables. You also can change the capacity of the tables on an individual basis if needed by changing the memory allocation for the table.

ARP cache and static ARP table

The ARP cache contains entries that map IP addresses to MAC addresses. Generally, the entries are for devices that are directly attached to the Layer 3 Switch.

An exception is an ARP entry for an interface-based static IP route that goes to a destination that is one or more router hops away. For this type of entry, the MAC address is either the destination device MAC address or the MAC address of the router interface that answered an ARP request on behalf of the device, using proxy ARP.

1. The filter can be an Access Control List (ACL) or an IP access policy.

ARP cache

The ARP cache can contain dynamic (learned) entries and static (user-configured) entries. The software places a dynamic entry in the ARP cache when the Layer 3 Switch learns a device MAC address from an ARP request or ARP reply from the device.

The software can learn an entry when the Layer 2 Switch or Layer 3 Switch receives an ARP request from another IP forwarding device or an ARP reply. Here is an example of a dynamic entry:

	IP Address	MAC Address	Type	Age	Port
1	207.95.6.102	0800.5afc.ea21	Dynamic	0	6

Each entry contains the destination device IP address and MAC address.

Static ARP table

In addition to the ARP cache, Layer 3 Switches have a static ARP table. Entries in the static ARP table are user-configured. You can add entries to the static ARP table regardless of whether or not the device the entry is for is connected to the Layer 3 Switch.

NOTE

Layer 3 Switches have a static ARP table. Layer 2 Switches do not.

The software places an entry from the static ARP table into the ARP cache when the entry interface comes up.

Here is an example of a static ARP entry.

Index	IP Address	MAC Address	Port
1	207.95.6.111	0800.093b.d210	1/1

Each entry lists the information you specified when you created the entry.

Displaying ARP entries

To display ARP entries, refer to the following sections:

- [“Displaying the ARP cache”](#) on page 1070 – Layer 3 Switch
- [“Displaying the static ARP table”](#) on page 1072 – Layer 3 Switch only
- [“Displaying ARP entries”](#) on page 1081 – Layer 2 Switch

To configure other ARP parameters, refer to the following sections:

- [“ARP parameter configuration”](#) on page 981 – Layer 3 Switch only

To increase the size of the ARP cache and static ARP table, refer to the following:

- For dynamic entries, refer to the section [“Displaying and modifying system parameter default settings”](#) on page 578. The `<ip-arp>` parameter controls the ARP cache size.
- Static entries, [“Changing the maximum number of entries the static ARP table can hold”](#) on page 986 (Layer 3 Switches only). The `<ip-static-arp>` parameter controls the static ARP table size.

IP route table

The IP route table contains paths to IP destinations.

NOTE

Layer 2 Switches do not have an IP route table. A Layer 2 Switch sends all packets addressed to another subnet to the default gateway, which you specify when you configure the basic IP information on the Layer 2 Switch.

The IP route table can receive the paths from the following sources:

- A directly-connected destination, which means there are no router hops to the destination
- A static IP route, which is a user-configured route
- A route learned through RIP
- A route learned through OSPF
- A route learned through BGP4

The IP route table contains the best path to a destination:

- When the software receives paths from more than one of the sources listed above, the software compares the administrative distance of each path and selects the path with the lowest administrative distance. The administrative distance is a protocol-independent value from 1 through 255.
- When the software receives two or more best paths from the same source and the paths have the same metric (cost), the software can load share traffic among the paths based on destination host or network address (based on the configuration and the Layer 3 Switch model).

Here is an example of an entry in the IP route table.

Destination	NetMask	Gateway	Port	Cost	Type
1.1.0.0	255.255.0.0	99.1.1.2	1/1	2	R

Each IP route table entry contains the destination IP address and subnet mask and the IP address of the next-hop router interface to the destination. Each entry also indicates the port attached to the destination or the next-hop to the destination, the route IP metric (cost), and the type. The type indicates how the IP route table received the route:

- To display the IP route table, refer to [“Displaying the IP route table”](#) on page 1074 (Layer 3 Switch only).
- To configure a static IP route, refer to [“Static routes configuration”](#) on page 991 (Layer 3 Switch only).
- To clear a route from the IP route table, refer to [“Clearing IP routes”](#) on page 1077 (Layer 3 Switch only).
- To increase the size of the IP route table for learned and static routes, refer to the section [“Displaying and modifying system parameter default settings”](#) on page 578:
 - For learned routes, modify the `<ip-route>` parameter.
 - For static routes, modify the `<ip-static-route>` parameter.

IP forwarding cache

The IP forwarding cache provides a fast-path mechanism for forwarding IP packets. The cache contains entries for IP destinations. When a Brocade Layer 3 Switch has completed processing and addressing for a packet and is ready to forward the packet, the device checks the IP forwarding cache for an entry to the packet destination:

- If the cache contains an entry with the destination IP address, the device uses the information in the entry to forward the packet out the ports listed in the entry. The destination IP address is the address of the packet final destination. The port numbers are the ports through which the destination can be reached.
- If the cache does not contain an entry and the traffic does not qualify for an entry in the session table instead, the software can create an entry in the forwarding cache.

Each entry in the IP forwarding cache has an age timer. If the entry remains unused for ten minutes, the software removes the entry. The age timer is not configurable.

Here is an example of an entry in the IP forwarding cache.

	IP Address	Next Hop	MAC	Type	Port	Vlan	Pri
1	192.168.1.11	DIRECT	0000.0000.0000	PU	n/a		0

Each IP forwarding cache entry contains the IP address of the destination, and the IP address and MAC address of the next-hop router interface to the destination. If the destination is actually an interface configured on the Layer 3 Switch itself, as shown here, then next-hop information indicates this. The port through which the destination is reached is also listed, as well as the VLAN and Layer 4 QoS priority associated with the destination if applicable.

To display the IP forwarding cache, refer to [“Displaying the forwarding cache”](#) on page 1073.

NOTE

You cannot add static entries to the IP forwarding cache, although you can increase the number of entries the cache can contain. Refer to the section [“Displaying and modifying system parameter default settings”](#) on page 578.

Layer 4 session table

The Layer 4 session provides a fast path for forwarding packets. A **session** is an entry that contains complete Layer 3 and Layer 4 information for a flow of traffic. Layer 3 information includes the source and destination IP addresses. Layer 4 information includes the source and destination TCP and UDP ports. For comparison, the IP forwarding cache contains the Layer 3 destination address but does not contain the other source and destination address information of a Layer 4 session table entry.

The Layer 2 Switch or Layer 3 Switch selects the session table instead of the IP forwarding table for fast-path forwarding for the following features:

- Layer 4 Quality-of-Service (QoS) policies
- IP access policies

To increase the size of the session table, refer to the section [“Displaying and modifying system parameter default settings”](#) on page 578. The ip-qos-session parameter controls the size of the session table.

IP route exchange protocols

Brocade Layer 3 Switches support the following IP route exchange protocols:

- Routing Information Protocol (RIP)
- Open Shortest Path First (OSPF)
- Border Gateway Protocol version 4 (BGP4)

All these protocols provide routes to the IP route table. You can use one or more of these protocols, in any combination. The protocols are disabled by default. For configuration information, refer to the following:

- [Chapter 29, “RIP \(IPv4\)”](#)
- [Chapter 31, “OSPF version 2 \(IPv4\)”](#)
- [Chapter 33, “BGP \(IPv4\)”](#)

IP multicast protocols

Brocade Layer 3 Switches also support the following Internet Group Membership Protocol (IGMP) based IP multicast protocols:

- Protocol Independent Multicast – Dense mode (PIM-DM)
- Protocol Independent Multicast – Sparse mode (PIM-SM)
- Distance Vector Multicast Routing Protocol (DVMRP)

For configuration information, refer to [Chapter 36, “IP Multicast Protocols”](#).

NOTE

Brocade Layer 2 Switches support IGMP and can forward IP multicast packets. Refer to [Chapter 34, “IP Multicast Traffic Reduction on Brocade FastIron X Series switches”](#) and [Chapter 35, “IP Multicast Traffic Reduction for FastIron WS and Brocade FCX and ICX Switches”](#).

IP interface redundancy protocols

You can configure a Brocade Layer 3 Switch to back up an IP interface configured on another Brocade Layer 3 Switch. If the link for the backed up interface becomes unavailable, the other Layer 3 Switch can continue service for the interface. This feature is especially useful for providing a backup to a network default gateway.

Brocade Layer 3 Switches support the following IP interface redundancy protocols:

- Virtual Router Redundancy Protocol (VRRP) – A standard router redundancy protocol based on RFC 2338. You can use VRRP to configure Brocade Layer 3 Switches and third-party routers to back up IP interfaces on other Brocade Layer 3 Switches or third-party routers.
- Virtual Router Redundancy Protocol Extended (VRRP-E) – A Brocade extension to standard VRRP that adds additional features and overcomes limitations in standard VRRP. You can use VRRP-E only on Brocade Layer 3 Switches.

For configuration information, refer to the [Chapter 39, “VRRP and VRRP-E”](#).

ACLs and IP access policies

Brocade Layer 3 Switches provide two mechanisms for filtering IP traffic:

- Access Control Lists (ACLs)
- IP access policies

Both methods allow you to filter packets based on Layer 3 and Layer 4 source and destination information.

ACLs also provide great flexibility by providing the input to various other filtering mechanisms such as route maps, which are used by BGP4.

IP access policies allow you to configure QoS based on sessions (Layer 4 traffic flows).

Only one of these filtering mechanisms can be enabled on a Brocade device at a time. Brocade devices can store forwarding information for both methods of filtering in the session table.

For configuration information, [Chapter 40, “Rule-Based IP ACLs”](#)

Basic IP parameters and defaults – Layer 3 Switches

IP is enabled by default. The following IP-based protocols are all disabled by default:

- Routing protocols:
 - Routing Information Protocol (RIP) – refer to [Chapter 29, “RIP \(IPv4\)”](#)
 - Open Shortest Path First (OSPF) – refer to [Chapter 31, “OSPF version 2 \(IPv4\)”](#)
 - Border Gateway Protocol version 4 (BGP4) – refer to [Chapter 33, “BGP \(IPv4\)”](#)
- Multicast protocols:
 - Internet Group Membership Protocol (IGMP) – refer to [“Global IP multicast parameters”](#) on page 1517
 - Protocol Independent Multicast Dense (PIM-DM) – refer to [“PIM Dense”](#) on page 1522
 - Protocol Independent Multicast Sparse (PIM-SM) – refer to [“PIM Sparse”](#) on page 1531
- Router redundancy protocols:
 - Virtual Router Redundancy Protocol Extended (VRRP-E) – refer to [Chapter 39, “VRRP and VRRP-E”](#)
 - Virtual Router Redundancy Protocol (VRRP) – refer to [Chapter 39, “VRRP and VRRP-E”](#)

The following tables list the Layer 3 Switch IP parameters, their default values, and where to find configuration information.

NOTE

For information about parameters in other protocols based on IP, such as RIP, OSPF, and so on, refer to the configuration chapters for those protocols.

When parameter changes take effect

Most IP parameters described in this chapter are dynamic. They take effect immediately, as soon as you enter the CLI command or select the Web Management Interface option. You can verify that a dynamic change has taken effect by displaying the running-config. To display the running-config, enter the **show running-config** or **write terminal** command at any CLI prompt. (You cannot display the running-config from the Web Management Interface.)

To save a configuration change permanently so that the change remains in effect following a system reset or software reload, save the change to the startup-config file:

- To save configuration changes to the startup-config file, enter the **write memory** command from the Privileged EXEC level of any configuration level of the CLI.
- To save the configuration changes using the Web Management Interface, select the Save link at the bottom of the dialog. Select Yes when prompted to save the configuration change to the startup-config file on the device flash memory. You also can access the dialog for saving configuration changes by clicking on Command in the tree view, then clicking on *Save to Flash*.

Changes to memory allocation require you to reload the software after you save the changes to the startup-config file. When reloading the software is required to complete a configuration change described in this chapter, the procedure that describes the configuration change includes a step for reloading the software.

IP global parameters – Layer 3 Switches

[Table 164](#) lists the IP global parameters for Layer 3 Switches.

TABLE 164 IP global parameters – Layer 3 Switches

Parameter	Description	Default	For more information
IP state	The Internet Protocol, version 4	Enabled NOTE: You cannot disable IP.	n/a
IP address and mask notation	Format for displaying an IP address and its network mask information. You can enable one of the following: <ul style="list-style-type: none"> • Class-based format; example: 192.168.1.1 255.255.255.0 • Classless Interdomain Routing (CIDR) format; example: 192.168.1.1/24 	Class-based NOTE: Changing this parameter affects the display of IP addresses, but you can enter addresses in either format regardless of the display setting.	page 1065
Router ID	The value that routers use to identify themselves to other routers when exchanging route information. OSPF and BGP4 use router IDs to identify routers. RIP does not use the router ID.	The IP address configured on the lowest-numbered loopback interface. If no loopback interface is configured, then the lowest-numbered IP address configured on the device.	page 976

TABLE 164 IP global parameters – Layer 3 Switches (Continued)

Parameter	Description	Default	For more information
Maximum Transmission Unit (MTU)	The maximum length an Ethernet packet can be without being fragmented.	1500 bytes for Ethernet II encapsulation 1492 bytes for SNAP encapsulation	page 974
Address Resolution Protocol (ARP)	A standard IP mechanism that routers use to learn the Media Access Control (MAC) address of a device on the network. The router sends the IP address of a device in the ARP request and receives the device MAC address in an ARP reply.	Enabled	page 981
ARP rate limiting	Lets you specify a maximum number of ARP packets the device will accept each second. If the device receives more ARP packets than you specify, the device drops additional ARP packets for the remainder of the one-second interval.	Disabled	page 982
ARP age	The amount of time the device keeps a MAC address learned through ARP in the device ARP cache. The device resets the timer to zero each time the ARP entry is refreshed and removes the entry if the timer reaches the ARP age. NOTE: You also can change the ARP age on an individual interface basis. Refer to Table 165 on page 959.	Ten minutes	page 983
Proxy ARP	An IP mechanism a router can use to answer an ARP request on behalf of a host, by replying with the router own MAC address instead of the host.	Disabled	page 983
Static ARP entries	An ARP entry you place in the static ARP table. Static entries do not age out.	No entries	page 985
Time to Live (TTL)	The maximum number of routers (hops) through which a packet can pass before being discarded. Each router decreases a packet TTL by 1 before forwarding the packet. If decreasing the TTL causes the TTL to be 0, the router drops the packet instead of forwarding it.	64 hops	page 987
Directed broadcast forwarding	A directed broadcast is a packet containing all ones (or in some cases, all zeros) in the host portion of the destination IP address. When a router forwards such a broadcast, it sends a copy of the packet out each of its enabled IP interfaces. NOTE: You also can enable or disable this parameter on an individual interface basis. Refer to Table 165 on page 959.	Disabled	page 987
Directed broadcast mode	The packet format the router treats as a directed broadcast. The following formats can be directed broadcast: <ul style="list-style-type: none"> All ones in the host portion of the packet destination address. All zeroes in the host portion of the packet destination address. 	All ones NOTE: If you enable all-zeroes directed broadcasts, all-ones directed broadcasts remain enabled.	page 988

TABLE 164 IP global parameters – Layer 3 Switches (Continued)

Parameter	Description	Default	For more information
Source-routed packet forwarding	A source-routed packet contains a list of IP addresses through which the packet must pass to reach its destination.	Enabled	page 988
Internet Control Message Protocol (ICMP) messages	The Brocade Layer 3 Switch can send the following types of ICMP messages: <ul style="list-style-type: none"> • Echo messages (ping messages) • Destination Unreachable messages 	Enabled	page 989
ICMP Router Discovery Protocol (IRDP)	An IP protocol a router can use to advertise the IP addresses of its router interfaces to directly attached hosts. You can enable or disable the protocol, and change the following protocol parameters: <ul style="list-style-type: none"> • Forwarding method (broadcast or multicast) • Hold time • Maximum advertisement interval • Minimum advertisement interval • Router preference level NOTE: You also can enable or disable IRDP and configure the parameters on an individual interface basis. Refer to Table 165 on page 959.	Disabled	page 1004
Reverse ARP (RARP)	An IP mechanism a host can use to request an IP address from a directly attached router when the host boots.	Enabled	page 1007
Static RARP entries	An IP address you place in the RARP table for RARP requests from hosts. NOTE: You must enter the RARP entries manually. The Layer 3 Switch does not have a mechanism for learning or dynamically generating RARP entries.	No entries	page 1008
Maximum BootP relay hops	The maximum number of hops away a BootP server can be located from a router and still be used by the router clients for network booting.	Four	page 1013
Domain name for Domain Name Server (DNS) resolver	A domain name (example: brocade.router.com) you can use in place of an IP address for certain operations such as IP pings, trace routes, and Telnet management connections to the router.	None configured	page 970
DNS default gateway addresses	A list of gateways attached to the router through which clients attached to the router can reach DNSs.	None configured	page 970
IP load sharing	A Brocade feature that enables the router to balance traffic to a specific destination across multiple equal-cost paths. <p>IP load sharing uses a hashing algorithm based on the source IP address, destination IP address, protocol field in the IP header, TCP, and UDP information.</p> NOTE: Load sharing is sometimes called Equal Cost Multi Path (ECMP).	Enabled	page 1001

TABLE 164 IP global parameters – Layer 3 Switches (Continued)

Parameter	Description	Default	For more information
Maximum IP load sharing paths	The maximum number of equal-cost paths across which the Layer 3 Switch is allowed to distribute traffic.	Four	page 1004
Origination of default routes	You can enable a router to originate default routes for the following route exchange protocols, on an individual protocol basis: <ul style="list-style-type: none"> • RIP • OSPF • BGP4 	Disabled	page 1202 page 1236 page 1352
Default network route	The router uses the default network route if the IP route table does not contain a route to the destination and also does not contain an explicit default route (0.0.0.0 0.0.0.0 or 0.0.0.0/0).	None configured	page 1000
Static route	An IP route you place in the IP route table.	No entries	page 991
Source interface	The IP address the router uses as the source address for Telnet, RADIUS, or TACACS/TACACS+ packets originated by the router. The router can select the source address based on either of the following: <ul style="list-style-type: none"> • The lowest-numbered IP address on the interface the packet is sent on. • The lowest-numbered IP address on a specific interface. The address is used as the source for all packets of the specified type regardless of interface the packet is sent on. 	The lowest-numbered IP address on the interface the packet is sent on.	page 977

IP interface parameters – Layer 3 Switches

[Table 165](#) lists the interface-level IP parameters for Layer 3 Switches.

TABLE 165 IP interface parameters – Layer 3 Switches

Parameter	Description	Default	For more information
IP state	The Internet Protocol, version 4	Enabled NOTE: You cannot disable IP.	n/a
IP address	A Layer 3 network interface address NOTE: Layer 2 Switches have a single IP address used for management access to the entire device. Layer 3 Switches have separate IP addresses on individual interfaces.	None configured ¹	page 964
Encapsulation type	The format of the packets in which the router encapsulates IP datagrams. The encapsulation format can be one of the following: <ul style="list-style-type: none"> • Ethernet II • SNAP 	Ethernet II	page 973

TABLE 165 IP interface parameters – Layer 3 Switches (Continued)

Parameter	Description	Default	For more information
Maximum Transmission Unit (MTU)	The maximum length (number of bytes) of an encapsulated IP datagram the router can forward.	1500 for Ethernet II encapsulated packets 1492 for SNAP encapsulated packets	page 975
ARP age	Locally overrides the global setting. Refer to Table 164 on page 956.	Ten minutes	page 983
Metric	A numeric cost the router adds to RIP routes learned on the interface. This parameter applies only to RIP routes.	1 (one)	page 1203
Directed broadcast forwarding	Locally overrides the global setting. Refer to Table 164 on page 956.	Disabled	page 987
ICMP Router Discovery Protocol (IRDP)	Locally overrides the global IRDP settings. Refer to Table 164 on page 956.	Disabled	page 1006
DHCP gateway stamp	The router can assist DHCP/BootP Discovery packets from one subnet to reach DHCP/BootP servers on a different subnet by placing the IP address of the router interface that receives the request in the request packet Gateway field. You can override the default and specify the IP address to use for the Gateway field in the packets. NOTE: UDP broadcast forwarding for client DHCP/BootP requests (bootps) must be enabled (this is enabled by default) and you must configure an IP helper address (the server IP address or a directed broadcast to the server subnet) on the port connected to the client.	The lowest-numbered IP address on the interface that receives the request	page 1012
DHCP Client-Based Auto-Configuration	Allows the switch to obtain IP addresses from a DHCP host automatically, for either a specified (leased) or infinite period of time.	Enabled	page 1028
DHCP Server	All FastIron devices can be configured to function as DHCP servers.	Disabled	page 1013

TABLE 165 IP interface parameters – Layer 3 Switches (Continued)

Parameter	Description	Default	For more information
UDP broadcast forwarding	<p>The router can forward UDP broadcast packets for UDP applications such as BootP. By forwarding the UDP broadcasts, the router enables clients on one subnet to find servers attached to other subnets.</p> <p>NOTE: To completely enable a client UDP application request to find a server on another subnet, you must configure an IP helper address consisting of the server IP address or the directed broadcast address for the subnet that contains the server. See the next row.</p>	<p>The router helps forward broadcasts for the following UDP application protocols:</p> <ul style="list-style-type: none"> • bootps • dns • netbios-dgm • netbios-ns • tacacs • tftp • time 	page 1010
IP helper address	The IP address of a UDP application server (such as a BootP or DHCP server) or a directed broadcast address. IP helper addresses allow the router to forward requests for certain UDP applications from a client on one subnet to a server on another subnet.	None configured	page 1011

1. Some devices have a factory default, such as 209.157.22.154, used for troubleshooting during installation. For Layer 3 Switches, the address is on module 1 port 1 (or 1/1).

Basic IP parameters and defaults – Layer 2 Switches

IP is enabled by default. The following tables list the Layer 2 Switch IP parameters, their default values, and where to find configuration information.

NOTE

Brocade Layer 2 Switches also provide IP multicast forwarding, which is enabled by default. For information about this feature, refer to [Chapter 34, “IP Multicast Traffic Reduction on Brocade FastIron X Series switches”](#).

IP global parameters – Layer 2 Switches

[Table 166](#) lists the IP global parameters for Layer 2 Switches.

TABLE 166 IP global parameters – Layer 2 Switches

Parameter	Description	Default	For more information
IP address and mask notation	Format for displaying an IP address and its network mask information. You can enable one of the following: <ul style="list-style-type: none"> Class-based format; example: 192.168.1.1 255.255.255.0 Classless Interdomain Routing (CIDR) format; example: 192.168.1.1/24 	Class-based NOTE: Changing this parameter affects the display of IP addresses, but you can enter addresses in either format regardless of the display setting.	page 1065
IP address	A Layer 3 network interface address NOTE: Layer 2 Switches have a single IP address used for management access to the entire device. Layer 3 Switches have separate IP addresses on individual interfaces.	None configured ¹	page 1037
Default gateway	The IP address of a locally attached router (or a router attached to the Layer 2 Switch by bridges or other Layer 2 Switches). The Layer 2 Switch and clients attached to it use the default gateway to communicate with devices on other subnets.	None configured	page 1037
Address Resolution Protocol (ARP)	A standard IP mechanism that networking devices use to learn the Media Access Control (MAC) address of another device on the network. The Layer 2 Switch sends the IP address of a device in the ARP request and receives the device MAC address in an ARP reply.	Enabled NOTE: You cannot disable ARP.	n/a
ARP age	The amount of time the device keeps a MAC address learned through ARP in the device ARP cache. The device resets the timer to zero each time the ARP entry is refreshed and removes the entry if the timer reaches the ARP age.	Ten minutes NOTE: You cannot change the ARP age on Layer 2 Switches.	n/a

TABLE 166 IP global parameters – Layer 2 Switches (Continued)

Parameter	Description	Default	For more information
Time to Live (TTL)	The maximum number of routers (hops) through which a packet can pass before being discarded. Each router decreases a packet TTL by 1 before forwarding the packet. If decreasing the TTL causes the TTL to be 0, the router drops the packet instead of forwarding it.	64 hops	page 1039
Domain name for Domain Name Server (DNS) resolver	A domain name (example: brocade.router.com) you can use in place of an IP address for certain operations such as IP pings, trace routes, and Telnet management connections to the router.	None configured	page 1038
DNS default gateway addresses	A list of gateways attached to the router through which clients attached to the router can reach DNSs.	None configured	page 1038
Source interface	The IP address the Layer 2 Switch uses as the source address for Telnet, RADIUS, or TACACS/TACACS+ packets originated by the router. The Layer 2 Switch uses its management IP address as the source address for these packets.	The management IP address of the Layer 2 Switch. NOTE: This parameter is not configurable on Layer 2 Switches.	n/a
DHCP gateway stamp	The device can assist DHCP/BootP Discovery packets from one subnet to reach DHCP/BootP servers on a different subnet by placing the IP address of the router interface that forwards the packet in the packet Gateway field. You can specify up to 32 gateway lists. A gateway list contains up to eight gateway IP addresses. You activate DHCP assistance by associating a gateway list with a port. When you configure multiple IP addresses in a gateway list, the Layer 2 Switch inserts the addresses into the DHCP Discovery packets in a round robin fashion.	None configured	page 1043
DHCP Client-Based Auto-Configuration	Allows the switch to obtain IP addresses from a DHCP host automatically, for either a specified (leased) or infinite period of time.	Enabled	page 1028

1. Some devices have a factory default, such as 209.157.22.154, used for troubleshooting during installation. For Layer 3 Switches, the address is on port 1 (or 1/1).

Interface IP parameters – Layer 2 Switches

[Table 167](#) lists the interface-level IP parameters for Layer 2 Switches.

TABLE 167 Interface IP parameters – Layer 2 Switches

Parameter	Description	Default	For more information
DHCP gateway stamp	You can configure a list of DHCP stamp addresses for a port. When the port receives a DHCP/BootP Discovery packet from a client, the port places the IP addresses in the gateway list into the packet Gateway field.	None configured	page 1043

Configuring IP parameters – Layer 3 Switches

The following sections describe how to configure IP parameters. Some parameters can be configured globally while others can be configured on individual interfaces. Some parameters can be configured globally and overridden for individual interfaces.

NOTE

This section describes how to configure IP parameters for Layer 3 Switches. For IP configuration information for Layer 2 Switches, refer to [“Configuring IP parameters – Layer 2 Switches”](#) on page 1037.

Configuring IP addresses

You can configure an IP address on the following types of Layer 3 Switch interfaces:

- Ethernet port
- Virtual routing interface (also called a Virtual Ethernet or “VE”)
- Loopback interface

By default, you can configure up to 24 IP addresses on each interface.

You can increase this amount to up to 128 IP subnet addresses per port by increasing the size of the ip-subnet-port table.

On FWS devices, you can increase this to 128 IP addresses on each interface.

Refer to the section [“Displaying system parameter default values”](#) on page 578.

NOTE

Once you configure a virtual routing interface on a VLAN, you cannot configure Layer 3 interface parameters on individual ports. Instead, you must configure the parameters on the virtual routing interface itself.

Brocade devices support both classical IP network masks (Class A, B, and C subnet masks, and so on) and Classless Interdomain Routing (CIDR) network prefix masks:

- To enter a classical network mask, enter the mask in IP address format. For example, enter “209.157.22.99 255.255.255.0” for an IP address with a Class-C subnet mask.
- To enter a prefix network mask, enter a forward slash (/) and the number of bits in the mask immediately after the IP address. For example, enter “209.157.22.99/24” for an IP address that has a network mask with 24 significant bits (ones).

By default, the CLI displays network masks in classical IP address format (example: 255.255.255.0). You can change the display to prefix format. Refer to [“Changing the network mask display to prefix format”](#) on page 1065.

Assigning an IP address to an Ethernet port

To assign an IP address to port 1/1, enter the following commands.

```
Brocade(config)# interface ethernet 1/1
Brocade(config-if-1/1)# ip address 192.45.6.1 255.255.255.0
```

You also can enter the IP address and mask in CIDR format, as follows.

```
Brocade(config-if-1/1)# ip address 192.45.6.1/24
```

Syntax: [no] ip address <ip-addr> <ip-mask> [ospf-ignore | ospf-passive | secondary]

or

Syntax: [no] ip address <ip-addr>/<mask-bits> [ospf-ignore | ospf-passive | secondary]

The **ospf-ignore** | **ospf-passive** parameters modify the Layer 3 Switch defaults for adjacency formation and interface advertisement. Use one of these parameters if you are configuring multiple IP subnet addresses on the interface but you want to prevent OSPF from running on some of the subnets:

- **ospf-passive** – This option disables adjacency formation with OSPF neighbors. By default, when OSPF is enabled on an interface, the software forms OSPF router adjacencies between each primary IP address on the interface and the OSPF neighbor attached to the interface.
- **ospf-ignore** – This option disables OSPF adjacency formation and also disables advertisement of the interface into OSPF. The subnet is completely ignored by OSPF.

NOTE

The **ospf-passive** option disables adjacency formation but does not disable advertisement of the interface into OSPF. To disable advertisement in addition to disabling adjacency formation, you must use the **ospf-ignore** option.

Use the **secondary** parameter if you have already configured an IP address within the same subnet on the interface.

NOTE

When you configure more than one address in the same subnet, all but the first address are secondary addresses and do not form OSPF adjacencies.

NOTE

All physical IP interfaces on Brocade FastIron Layer 3 devices share the same MAC address. For this reason, if more than one connection is made between two devices, one of which is a Brocade FastIron Layer 3 device, Brocade recommends the use of virtual interfaces. It is not recommended to connect two or more physical IP interfaces between two routers.

Assigning an IP address to a loopback interface

Loopback interfaces are always up, regardless of the states of physical interfaces. They can add stability to the network because they are not subject to route flap problems that can occur due to unstable links between a Layer 3 Switch and other devices. You can configure up to eight loopback interfaces on a Chassis Layer 3 Switch and FWS devices. You can configure up to four loopback interfaces on a Compact Layer 3 Switch.

You can add up to 24 IP addresses to each loopback interface.

NOTE

If you configure the Brocade Layer 3 Switch to use a loopback interface to communicate with a BGP4 neighbor, you also must configure a loopback interface on the neighbor and configure the neighbor to use that loopback interface to communicate with the Brocade Layer 3 Switch. Refer to [“Adding a loopback interface”](#) on page 1353.

To add a loopback interface, enter commands such as those shown in the following example.

```
Brocade(config-bgp-router)# exit
Brocade(config)# interface loopback 1
Brocade(config-lbif-1)# ip address 10.0.0.1/24
```

Syntax: interface loopback <num>

The <num> parameter specifies the virtual interface number. You can specify from 1 to the maximum number of virtual interfaces supported on the device. To display the maximum number of virtual interfaces supported on the device, enter the **show default values** command. The maximum is listed in the System Parameters section, in the Current column of the virtual-interface row.

Refer to the syntax description in [“Assigning an IP address to an Ethernet port”](#) on page 965.

Assigning an IP address to a virtual interface

A virtual interface is a logical port associated with a Layer 3 Virtual LAN (VLAN) configured on a Layer 3 Switch. You can configure routing parameters on the virtual interface to enable the Layer 3 Switch to route protocol traffic from one Layer 3 VLAN to the other, without using an external router.¹

You can configure IP routing interface parameters on a virtual interface. This section describes how to configure an IP address on a virtual interface. Other sections in this chapter that describe how to configure interface parameters also apply to virtual interfaces.

NOTE

The Layer 3 Switch uses the lowest MAC address on the device (the MAC address of port 1 or 1/1) as the MAC address for all ports within all virtual interfaces you configure on the device.

1. The Brocade feature that allows routing between VLANs within the same device, without the need for external routers, is called Integrated Switch Routing (ISR).

To add a virtual interface to a VLAN and configure an IP address on the interface, enter commands such as the following.

```
Brocade(config)# vlan 2 name IP-Subnet_1.1.2.0/24
Brocade(config-vlan-2)# untag ethernet 1 to 4
Brocade(config-vlan-2)# router-interface ve1
Brocade(config-vlan-2)# interface ve1
Brocade(config-vif-1)# ip address 1.1.2.1/24
```

The first two commands in this example create a Layer 3 protocol-based VLAN name “IP-Subnet_1.1.2.0/24” and add a range of untagged ports to the VLAN. The **router-interface** command creates virtual interface 1 as the routing interface for the VLAN.

Syntax: **router-interface ve** <num>

The <num> variable specifies the virtual interface number. You can enter a number from 1 through 4095.

When configuring virtual routing interfaces on a device, you can specify a number from 1 through 4095. However, the total number of virtual routing interfaces that are configured must not exceed the system-max limit of 512. For more information on the number of virtual routing interfaces supported, refer to [“Allocating memory for more VLANs or virtual routing interfaces”](#) on page 795.

The last two commands change to the interface configuration level for the virtual interface and assign an IP address to the interface.

Syntax: **interface ve** <num>

Refer to the syntax description in [“Assigning an IP address to an Ethernet port”](#) on page 965.

Configuring IP follow on a virtual routing interface

IP Follow allows multiple virtual routing interfaces to share the same IP address. With this feature, one virtual routing interface is configured with an IP address, while the other virtual routing interfaces are configured to use that IP address, thus, they “follow” the virtual routing interface that has the IP address. This feature is helpful in conserving IP address space.

Configuration limitations and feature limitations for IP Follow on a virtual routing interface

- When configuring IP Follow, the primary virtual routing interface should not have ACL or DoS Protection configured. It is recommended that you create a dummy virtual routing interface as the primary and use the IP-follow virtual routing interface for the network.
- Global Policy Based Routing is not supported when IP Follow is configured.
- IPv6 is not supported with **ip-follow**.
- FastIron devices support **ip-follow** with OSPF and VRRP protocols only.

Configuration syntax for IP Follow on a virtual routing interface

Configure IP Follow by entering commands such as the following.

```
Brocade(config)# vlan 2 name IP-Subnet_1.1.2.0/24
Brocade(config-vlan-2)# untag ethernet 1 to 4
Brocade(config-vlan-2)# router-interface ve1
Brocade(config-vlan-2)# interface ve 1
Brocade(config-vif-1)# ip address 10.10.2.1/24
```

```
Brocade(config-vif-1)# interface ve 2
Brocade(config-vif-2)# ip follow ve 1
Brocade(config-vif-2)# interface ve 3
Brocade(config-vif-3)# ip follow ve 1
```

Syntax: [no] ip follow ve <number>

For <number>, enter the ID of the virtual routing interface.

Use the **no** form of the command to disable the configuration.

Virtual routing interface 2 and 3 do not have their own IP subnet addresses, but are sharing the IP address of virtual routing interface 1.

Deleting an IP address

To delete an IP address, enter the **no ip address** command.

```
Brocade(config-if-e1000-1)# no ip address 1.1.2.1
```

This command deletes IP address 1.1.2.1. You do not need to enter the subnet mask.

To delete all IP addresses from an interface, enter the **no ip address *** command.

```
Brocade(config-if-e1000-1)# no ip address *
```

Syntax: no ip address <ip-addr> | *

Configuring 31-bit subnet masks on point-to-point networks

NOTE

31-bit subnet masks are supported on FSX, FCX, and ICX 6610 devices running the full Layer 3 image.

To conserve IPv4 address space, a 31-bit subnet mask can be assigned to point-to-point networks. Support for an IPv4 address with a 31-bit subnet mask is described in RFC 3021.

With IPv4, four IP addresses with a 30-bit subnet mask are allocated on point-to-point networks. In contrast, a 31-bit subnet mask uses only two IP addresses: all zero bits and all one bits in the host portion of the IP address. The two IP addresses are interpreted as host addresses, and do not require broadcast support because any packet that is transmitted by one host is always received by the other host at the receiving end. Therefore, directed broadcast on a point-to-point interface is eliminated.

IP-directed broadcast CLI configuration at the global level, or the per interface level, is not applicable on interfaces configured with a 31-bit subnet mask IP address.

When the 31-bit subnet mask address is configured on a point-to-point link, using network addresses for broadcast purposes is not allowed. For example, in an IPV4 broadcast scheme, the following subnets can be configured:

- 10.10.10.1 - Subnet for directed broadcast: {<Network-number>, -1}
- 10.10.10.0 - Subnet for network address: {<Network-number>, 0}

In a point-to-point link with a 31-bit subnet mask, the previous two addresses are interpreted as host addresses and packets are not rebroadcast.

Configuring an IPv4 address with a 31-bit subnet mask

To configure an IPv4 address with a 31-bit subnet mask, enter the following commands.

You can configure an IPv4 address with a 31-bit subnet mask on any interface (for example, Ethernet, loopback, VE, or tunnel interfaces).

```
Brocade(config)# interface ethernet 1/1/5
Brocade(config-if-e1000-1/5)# ip address 9.9.9.9 255.255.255.254
```

You can also enter the IP address and mask in the Classless Inter-domain Routing (CIDR) format, as follows.

```
Brocade(config-if-e1000-1/1/5)# ip address 9.9.9.9/31
```

Syntax: [no] ip address <ip-address> <ip-mask>

Syntax: [no] ip address <ip-address>/<subnet mask-bits>

The <ip-address> variable specifies the host address. The <ip-mask> variable specifies the IP network mask. The <subnet mask-bits> variable specifies the network prefix mask.

To disable configuration for an IPv4 address with a 31-bit subnet mask on any interface, use the **no** form of the command.

You cannot configure a secondary IPv4 address with a 31-bit subnet mask on any interface. The following error message is displayed when a secondary IPv4 address with a 31-bit subnet mask is configured.

```
Error: Cannot assign /31 subnet address as secondary
```

Configuration example

Figure 111 shows the usage of 31- and 24-bit subnet masks in configuring IP addresses.

FIGURE 111 Configured 31-bit and 24-bit subnet masks

Router A is connected to Router B as a point-to-point link with 1.1.1.0/31 subnet. There are only two available addresses in this subnet, 1.1.1.0 on Router A and 1.1.1.1 on Router B,

Routers B and C are connected by a regular 24-bit subnet. Router C can either be a switch with many hosts belonging to the 2.2.2.2/24 subnet connected to it, or it can be a router.

Router A

```
RouterA(config)# interface ethernet 1/1/1
RouterA(config-if-e1000-1/1/1)# ip address 1.1.1.0/31
```

Router B

```
RouterB(config)# interface ethernet 1/1/1
RouterB(config-if-e1000-1/1/1)# ip address 1.1.1.1/31
RouterB(config-if-e1000-1/1/1)# exit
```

```
RouterB(config# interface ethernet 1/3/1
RouterB(config-if-e1000-1/3/1)# ip address 2.2.2.1/24
```

Router C

```
RouterC(config# interface ethernet 1/3/1
RouterC(config-if-e1000-1/3/1)# ip address 2.2.2.2/24
```

Displaying information for a 31-bit subnet mask

Use the following commands to display information for the 31-bit subnet mask:

- **show run interface**
- **show ip route**
- **show ip cache**

Configuring DNS resolver

The Domain Name System (DNS) resolver is a feature in a Layer 2 or Layer 3 switch that sends and receives queries to and from the DNS server on behalf of a client.

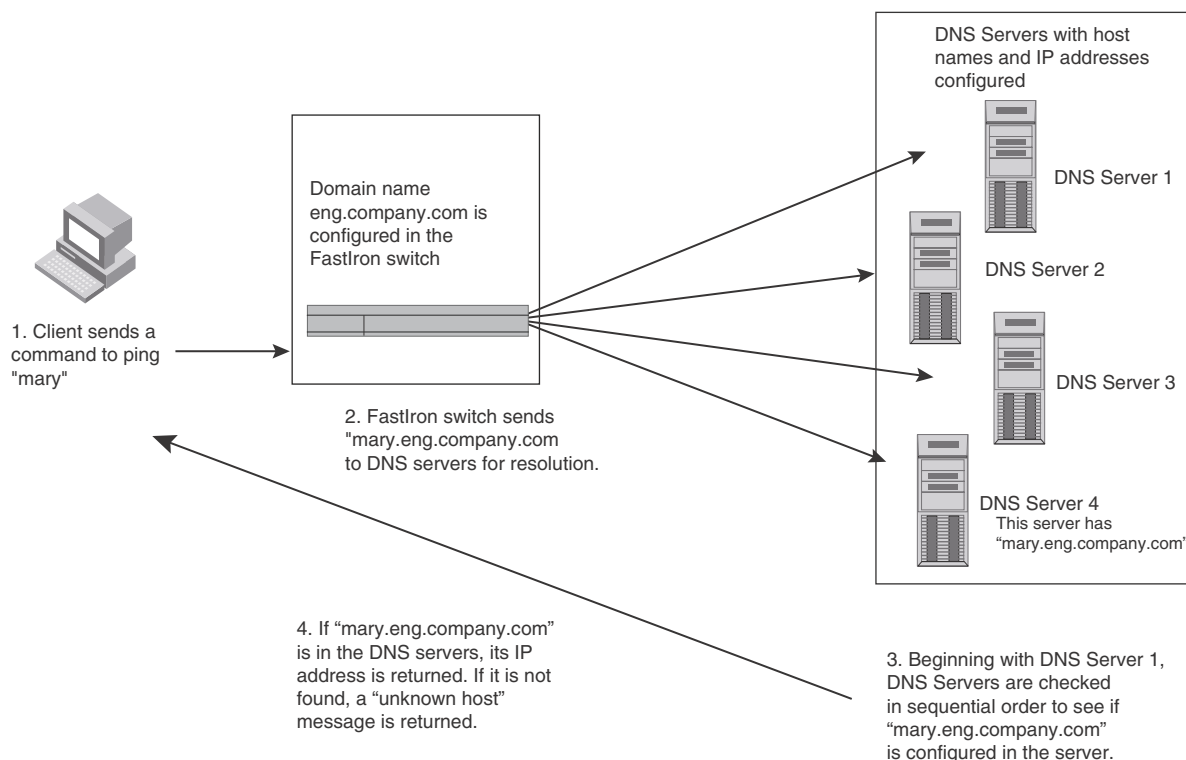

You can create a list of domain names that can be used to resolve host names. This list can have more than one domain name. When a client performs a DNS query, all hosts within the domains in the list can be recognized and queries can be sent to any domain on the list.

After you define a domain name, the Brocade device automatically appends the appropriate domain to a host and forwards it to the DNS servers for resolution.

For example, if the domain “ds.company.com” is defined on a Layer 2 or Layer 3 switch and you want to initiate a ping to “mary”, you must reference only the host name instead of the host name and its domain name. For example, you could enter the following command to initiate the ping.

```
U:> ping mary
```

The Layer 2 or Layer 3 switch qualifies the host name by appending a domain name (for example, mary.ds1.company.com). This qualified name is sent to the DNS server for resolution. If there are four DNS servers configured, it is sent to the first DNS server. If the host name is not resolved, it is sent to the second DNS server. If a match is found, a response is sent back to the client with the host IP address. If no match is found, an “unknown host” message is returned. (Refer to [Figure 112.](#))

FIGURE 112 DNS resolution with one domain name

Defining a domain name

To define a domain to resolve host names, enter the **ip dns domain-name** command.

```
Brocade(config)# ip dns domain-name ds.company.com
```

Syntax: [no] **ip dns domain-name** <domain-name>

Enter the domain name for <domain-name>.

Defining DNS server addresses

You can configure the Brocade device to recognize up to four DNS servers. The first entry serves as the primary default address. If a query to the primary address fails to be resolved after three attempts, the next DNS address is queried (also up to three times). This process continues for each defined DNS address until the query is resolved. The order in which the default DNS addresses are polled is the same as the order in which you enter them.

To define DNS servers, enter the **ip dns server-address** command.

```
Brocade(config)# ip dns server-address 209.157.22.199 205.96.7.15 208.95.7.25  
201.98.7.15
```

Syntax: [no] **ip dns server-address** <ip-addr> [<ip-addr>] [<ip-addr>] [<ip-addr>]

In this example, the first IP address entered becomes the primary DNS address and all others are secondary addresses. Because IP address 201.98.7.15 is the last address listed, it is also the last address consulted to resolve a query.

Defining a domain list

If you want to use more than one domain name to resolve host names, you can create a list of domain names. For example, enter the commands such as the following.

```
Brocade(config)# ip dns domain-list company.com
Brocade(config)# ip dns domain-list ds.company.com
Brocade(config)# ip dns domain-list hw_company.com
Brocade(config)# ip dns domain-list qa_company.com
Brocade(config)#
```

The domain names are tried in the order you enter them

Syntax: [no] ip dns domain-list <domain-name>

Using a DNS name to initiate a trace route

Suppose you want to trace the route from a Brocade Layer 3 Switch to a remote server identified as NYC02 on domain newyork.com. Because the NYC02@ds1.newyork.com domain is already defined on the Layer 3 Switch, you need to enter only the host name, NYC02, as noted in the following example.

```
Brocade# traceroute nyc02
```

Syntax: traceroute <host-ip-addr> [maxttl <value>] [minttl <value>] [numeric] [timeout <value>]
[source-ip <ip addr>]

The only required parameter is the IP address of the host at the other end of the route.

After you enter the command, a message indicating that the DNS query is in process and the current gateway address (IP address of the domain name server) being queried appear on the screen.

```
Type Control-c to abort
Sending DNS Query to 209.157.22.199
Tracing Route to IP node 209.157.22.80
To ABORT Trace Route, Please use stop-traceroute command.
Traced route to target IP node 209.157.22.80:
  IP Address      Round Trip Time1    Round Trip Time2
  207.95.6.30     93 msec            121 msec
```

NOTE

In the previous example, 209.157.22.199 is the IP address of the domain name server (default DNS gateway address), and 209.157.22.80 represents the IP address of the NYC02 host.

Configuring packet parameters

You can configure the following packet parameters on Layer 3 Switches. These parameters control how the Layer 3 Switch sends IP packets to other devices on an Ethernet network. The Layer 3 Switch always places IP packets into Ethernet packets to forward them on an Ethernet port.

- **Encapsulation type** – The format for the Layer 2 packets within which the Layer 3 Switch sends IP packets.
- **Maximum Transmission Unit (MTU)** – The maximum length of IP packet that a Layer 2 packet can contain. IP packets that are longer than the MTU are fragmented and sent in multiple Layer 2 packets. You can change the MTU globally or on individual ports:
 - **Global MTU** – The default MTU value depends on the encapsulation type on a port and is 1500 bytes for Ethernet II encapsulation and 1492 bytes for SNAP encapsulation.
 - **Port MTU** – A port default MTU depends on the encapsulation type enabled on the port.

Changing the encapsulation type

The Layer 3 Switch encapsulates IP packets into Layer 2 packets, to send the IP packets on the network. (A Layer 2 packet is also called a MAC layer packet or an Ethernet frame.) The source address of a Layer 2 packet is the MAC address of the Layer 3 Switch interface sending the packet. The destination address can be one of the following:

- The MAC address of the IP packet destination. In this case, the destination device is directly connected to the Layer 3 Switch.
- The MAC address of the next-hop gateway toward the packet destination.
- An Ethernet broadcast address.

The entire IP packet, including the source and destination address and other control information and the data, is placed in the data portion of the Layer 2 packet. Typically, an Ethernet network uses one of two different formats of Layer 2 packet:

- Ethernet II
- Ethernet SNAP (also called IEEE 802.3)

The control portions of these packets differ slightly. All IP devices on an Ethernet network must use the same format. Brocade Layer 3 Switches use Ethernet II by default. You can change the IP encapsulation to Ethernet SNAP on individual ports if needed.

NOTE

All devices connected to the Layer 3 Switch port must use the same encapsulation type.

To change the IP encapsulation type on interface 5 to Ethernet SNAP, enter the following commands.

```
Brocade(config)# interface ethernet 5
Brocade(config-if-e1000-5)# ip encapsulation snap
```

Syntax: `ip encapsulation snap | ethernet_ii`

Changing the MTU

The Maximum Transmission Unit (MTU) is the maximum length of IP packet that a Layer 2 packet can contain. IP packets that are longer than the MTU are fragmented and sent in multiple Layer 2 packets. You can change the MTU globally or on individual ports.

The default MTU is 1500 bytes for Ethernet II packets and 1492 for Ethernet SNAP packets.

MTU enhancements

Brocade devices contain the following enhancements to jumbo packet support:

- Hardware forwarding of Layer 3 jumbo packets – Layer 3 IP unicast jumbo packets received on a port that supports the frame MTU size and forwarded to another port that also supports the frame MTU size are forwarded in hardware. Previous releases support hardware forwarding of Layer 2 jumbo frames only.
- ICMP unreachable message if a frame is too large to be forwarded – If a jumbo packet has the Do not Fragment (DF) bit set, and the outbound interface does not support the packet MTU size, the Brocade device sends an ICMP unreachable message to the device that sent the packet.

NOTE

These enhancements apply only to transit traffic forwarded through the Brocade device.

Configuration considerations for increasing the MTU

- The MTU command is applicable to VEs and physical IP interfaces. It applies to traffic routed between networks.
- You cannot use this command to set Layer 2 maximum frame sizes per interface. The global **jumbo** command causes all interfaces to accept Layer 2 frames.
- When you increase the MTU size of a port, the increase uses system resources. Increase the MTU size only on the ports that need it. For example, if you have one port connected to a server that uses jumbo frames and two other ports connected to clients that can support the jumbo frames, increase the MTU only on those three ports. Leave the MTU size on the other ports at the default value (1500 bytes). Globally increase the MTU size only if needed.

Forwarding traffic to a port with a smaller MTU size

NOTE

This feature is not supported on FastIron X Series devices.

In order to forward traffic from a port with 1500 MTU configured to a port that has a smaller MTU (for example, 750) size, you must apply the **mtu-exceed forward** global command. To remove this setting, enter the **mtu-exceed hard-drop** command. **MTU-exceed hard-drop** is the default state of the router.

Syntax:mtu-exceed [forward | hard-drop]

- **forward** - forwards a packet from a port with a larger MTU to a port with a smaller MTU
- **hard-drop** - resets to default, removes the forward function.

Globally changing the Maximum Transmission Unit

The Maximum Transmission Unit (MTU) is the maximum size an IP packet can be when encapsulated in a Layer 2 packet. If an IP packet is larger than the MTU allowed by the Layer 2 packet, the Layer 3 Switch fragments the IP packet into multiple parts that will fit into the Layer 2 packets, and sends the parts of the fragmented IP packet separately, in different Layer 2 packets. The device that receives the multiple fragments of the IP packet reassembles the fragments into the original packet.

You can increase the MTU size to accommodate jumbo packet sizes up to up to 10,232 bytes in an IronStack. Devices that are not part of an IronStack support up to 10,240 bytes.

To globally enable jumbo support on all ports of a FastIron device, enter commands such as the following.

```
Brocade(config)# jumbo
Brocade(config)# write memory
Brocade(config)# end
Brocade# reload
```

Syntax: [no] jumbo

NOTE

You must save the configuration change and then reload the software to enable jumbo support.

Changing the MTU on an individual port

By default, the maximum Ethernet MTU sizes are as follows:

- 1500 bytes – The maximum for Ethernet II encapsulation
- 1492 bytes – The maximum for SNAP encapsulation

When jumbo mode is enabled, the maximum Ethernet MTU sizes are as follows:

- 10,240 bytes– The maximum for Ethernet II encapsulation
- 10,240 bytes – The maximum for SNAP encapsulation

NOTE

If you set the MTU of a port to a value lower than the global MTU and from 576 through 1499, the port fragments the packets. However, if the port MTU is exactly 1500 and this is larger than the global MTU, the port drops the packets.

NOTE

The **ip mtu** command is not supported on FWS devices.

NOTE

You must save the configuration change and then reload the software to enable jumbo support.

To change the MTU for interface 1/5 to 1000, enter the following commands.

```
Brocade(config)# interface ethernet 1/5
Brocade(config-if-1/5)# ip mtu 1000
Brocade(config-if-1/5)# write memory
Brocade(config-if-1/5)# end
Brocade# reload
```

Syntax: [no] ip mtu <num>

The `<num>` parameter specifies the MTU. Ethernet II packets can hold IP packets from 576 through 1500 bytes long. If jumbo mode is enabled, Ethernet II packets can hold IP packets up to 10,240 bytes long. Ethernet SNAP packets can hold IP packets from 576 through 1492 bytes long. If jumbo mode is enabled, SNAP packets can hold IP packets up to 10,240 bytes long. The default MTU for Ethernet II packets is 1500. The default MTU for SNAP packets is 1492.

Path MTU discovery (RFC 1191) support

FastIron X Series devices support the path MTU discovery method described in RFC 1191. When the Brocade device receives an IP packet that has its Do not Fragment (DF) bit set, and the packet size is greater than the MTU value of the outbound interface, then the Brocade device returns an ICMP Destination Unreachable message to the source of the packet, with the Code indicating "fragmentation needed and DF set". The ICMP Destination Unreachable message includes the MTU of the outbound interface. The source host can use this information to help determine the maximum MTU of a path to a destination.

RFC 1191 is supported on all interfaces.

Changing the router ID

In most configurations, a Layer 3 Switch has multiple IP addresses, usually configured on different interfaces. As a result, a Layer 3 Switch identity to other devices varies depending on the interface to which the other device is attached. Some routing protocols, including Open Shortest Path First (OSPF) and Border Gateway Protocol version 4 (BGP4), identify a Layer 3 Switch by just one of the IP addresses configured on the Layer 3 Switch, regardless of the interfaces that connect the Layer 3 Switches. This IP address is the router ID.

NOTE

Routing Information Protocol (RIP) does not use the router ID.

NOTE

If you change the router ID, all current BGP4 sessions are cleared.

By default, the router ID on a Brocade Layer 3 Switch is one of the following:

- If the router has loopback interfaces, the default router ID is the IP address configured on the lowest numbered loopback interface configured on the Layer 3 Switch. For example, if you configure loopback interfaces 1, 2, and 3 as follows, the default router ID is 9.9.9.9/24:
 - Loopback interface 1, 9.9.9.9/24
 - Loopback interface 2, 4.4.4.4/24
 - Loopback interface 3, 1.1.1.1/24
- If the device does not have any loopback interfaces, the default router ID is the lowest numbered IP interface configured on the device.

If you prefer, you can explicitly set the router ID to any valid IP address. The IP address cannot be in use on another device in the network.

NOTE

Brocade Layer 3 Switches use the same router ID for both OSPF and BGP4. If the router is already configured for OSPF, you may want to use the router ID that is already in use on the router rather than set a new one. To display the router ID, enter the **show ip** command at any CLI level or select the IP->General links from the Configure tree in the Web Management Interface.

To change the router ID, enter a command such as the following.

```
Brocade(config)# ip router-id 209.157.22.26
```

Syntax: `ip router-id <ip-addr>`

The `<ip-addr>` can be any valid, unique IP address.

NOTE

You can specify an IP address used for an interface on the Brocade Layer 3 Switch, but do not specify an IP address in use by another device.

Specifying a single source interface for specified packet types

NOTE

This feature is supported on FWS, Brocade FCX Series switches, FastIron X Series Layer 3 switches, ICX 6430 and ICX 6450 switches.

When the Layer 3 Switch originates a packet of one of the following types, the source address of the packet is the lowest-numbered IP address on the interface that sends the packet:

- Telnet
- TACACS/TACACS+
- TFTP
- RADIUS
- Syslog
- SNMP
- SSH
- SNMP traps

You can configure the Layer 3 Switch to always use the lowest-numbered IP address on a specific Ethernet, loopback, or virtual interface as the source addresses for these packets. When configured, the Layer 3 Switch uses the same IP address as the source for all packets of the specified type, regardless of the ports that actually sends the packets.

Identifying a single source IP address for specified packets provides the following benefits:

- If your server is configured to accept packets only from specific IP addresses, you can use this feature to simplify configuration of the server by configuring the Brocade device to always send the packets from the same link or source address.
- If you specify a loopback interface as the single source for specified packets, servers can receive the packets regardless of the states of individual links. Thus, if a link to the server becomes unavailable but the client or server can be reached through another link, the client or server still receives the packets, and the packets still have the source IP address of the loopback interface.

The software contains separate CLI commands for specifying the source interface for specific packets. You can configure a source interface for one or more of these types of packets separately.

The following sections show the syntax for specifying a single source IP address for specific packet types.

Telnet packets

To specify the lowest-numbered IP address configured on a virtual interface as the device source for all Telnet packets, enter commands such as the following.

```
Brocade(config)# interface loopback 2
Brocade(config-lbif-2)# ip address 10.0.0.2/24
Brocade(config-lbif-2)# exit
Brocade(config)# ip telnet source-interface loopback 2
```

The commands in this example configure loopback interface 2, assign IP address 10.0.0.2/24 to the interface, then designate the interface as the source for all Telnet packets from the Layer 3 Switch.

The following commands configure an IP interface on an Ethernet port and designate the address port as the source for all Telnet packets from the Layer 3 Switch.

```
Brocade(config)# interface ethernet 1/4
Brocade(config-if-1/4)# ip address 209.157.22.110/24
Brocade(config-if-1/4)# exit
Brocade(config)# ip telnet source-interface ethernet 1/4
```

Syntax: [no] ip telnet source-interface ethernet [<slotnum>/]<portnum> | loopback <num> | ve <num>

The <slotnum> variable is required on chassis devices.

The <portnum> variable is a valid port number.

The <num> variable is a loopback interface or virtual interface number.

TACACS/TACACS+ packets

To specify the lowest-numbered IP address configured on a virtual interface as the device source for all TACACS/TACACS+ packets, enter commands such as the following.

```
Brocade(config)# interface ve 1
Brocade(config-vif-1)# ip address 10.0.0.3/24
Brocade(config-vif-1)# exit
Brocade(config)# ip tacacs source-interface ve 1
```

The commands in this example configure virtual interface 1, assign IP address 10.0.0.3/24 to the interface, then designate the interface as the source for all TACACS/TACACS+ packets from the Layer 3 Switch.

Syntax: [no] ip tacacs source-interface ethernet [<slotnum>/]<portnum> | loopback <num> | ve <num>

The <slotnum> variable is required on chassis devices.

The <portnum> variable is a valid port number.

The <num> variable is a loopback interface or virtual interface number.

RADIUS packets

To specify the lowest-numbered IP address configured on a virtual interface as the device source for all RADIUS packets, enter commands such as the following.

```

Brocade(config)# interface ve 1
Brocade(config-vif-1)# ip address 10.0.0.3/24
Brocade(config-vif-1)# exit
Brocade(config)# ip radius source-interface ve 1

```

The commands in this example configure virtual interface 1, assign IP address 10.0.0.3/24 to the interface, then designate the interface as the source for all RADIUS packets from the Layer 3 Switch.

Syntax: [no] **ip radius source-interface ethernet** [<slotnum>/<portnum> | **loopback** <num> | **ve** <num>]

The <slotnum> variable is required on chassis devices.

The <portnum> variable is a valid port number.

The <num> variable is a loopback interface or virtual interface number.

TFTP packets

To specify the lowest-numbered IP address configured on a virtual interface as the device source for all TFTP packets, enter commands such as the following.

```

Brocade(config)# interface ve 1
Brocade(config-vif-1)# ip address 10.0.0.3/24
Brocade(config-vif-1)# exit
Brocade(config)# ip tftp source-interface ve 1

```

The commands in this example configure virtual interface 1, assign IP address 10.0.0.3/24 to the interface, then designate the interface's address as the source address for all TFTP packets.

Syntax: [no] **ip tftp source-interface ethernet** [<slotnum>/<portnum> | **loopback** <num> | **ve** <num>]

The <slotnum> variable is required on chassis devices.

The <portnum> variable is a valid port number.

The <num> variable is a loopback interface or virtual interface number.

The default is the lowest-numbered IP address configured on the port through which the packet is sent. The address therefore changes, by default, depending on the port.

Syslog packets

To specify the lowest-numbered IP address configured on a virtual interface as the device source for all Syslog packets, enter commands such as the following.

```

Brocade(config)# interface ve 1
Brocade(config-vif-1)# ip address 10.0.0.4/24
Brocade(config-vif-1)# exit
Brocade(config)# ip syslog source-interface ve 1

```

The commands in this example configure virtual interface 1, assign IP address 10.0.0.4/24 to the interface, then designate the interface's address as the source address for all Syslog packets.

Syntax: [no] **ip syslog source-interface ethernet** [<slotnum>/<portnum> | **loopback** <num> | **ve** <num>]

The <slotnum> variable is required on chassis devices.

The `<portnum>` variable is a valid port number.

The `<num>` variable is a loopback interface or virtual interface number.

The default is the lowest-numbered IP or IPv6 address configured on the port through which the packet is sent. The address therefore changes, by default, depending on the port.

SNTP packets

To specify the lowest-numbered IP address configured on a virtual interface as the device source for all SNTP packets, enter commands such as the following.

```
Brocade(config)# interface ve 1
Brocade(config-vif-1)# ip address 10.0.0.5/24
Brocade(config-vif-1)# exit
Brocade(config)# ip sntp source-interface ve 1
```

The commands in this example configure virtual interface 1, assign IP address 10.0.0.5/24 to the interface, then designate the interface's address as the source address for all SNTP packets.

Syntax: `[no] ip sntp source-interface ethernet [<slotnum>]/<portnum> | loopback <num> | ve <num>`

The `<slotnum>` variable is required on chassis devices.

The `<portnum>` variable is a valid port number.

The `<num>` variable is a loopback interface or virtual interface number.

The default is the lowest-numbered IP or IPv6 address configured on the port through which the packet is sent. The address therefore changes, by default, depending on the port.

SSH packets

NOTE

When you specify a single SSH source, you can use only that source address to establish SSH management sessions with the Brocade device.

To specify the numerically lowest IP address configured on a loopback interface as the device source for all SSH packets, enter commands such as the following.

```
Brocade(config)# interface loopback 2
Brocade(config-lbif-2)# ip address 10.0.0.2/24
Brocade(config-lbif-2)# exit
Brocade(config)# ip ssh source-interface loopback 2
```

The commands in this example configure loopback interface 2, assign IP address 10.0.0.2/24 to the interface, then designate the interface as the source for all SSH packets from the Layer 3 Switch.

Syntax: `[no] ip ssh source-interface ethernet [<slotnum>]/<portnum> | loopback <num> | ve <num>`

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter is a valid port number.

The `<num>` parameter is a loopback interface or virtual interface number.

SNMP packets

To specify a loopback interface as the SNMP single source trap, enter commands such as the following.

```
Brocade(config)# interface loopback 1
Brocade(config-lbif-1)# ip address 10.0.0.1/24
Brocade(config-lbif-1)# exit
Brocade(config)# snmp-server trap-source loopback 1
```

The commands in this example configure loopback interface 1, assign IP address 10.00.1/24 to the loopback interface, then designate the interface as the SNMP trap source for this device. Regardless of the port the Brocade device uses to send traps to the receiver, the traps always arrive from the same source IP address.

Syntax: [no] **snmp-server trap-source ethernet** [<slotnum>/<portnum> | **loopback** <num> | **ve** <num>]

The <slotnum> variable is required on chassis devices.

The <portnum> variable is a valid port number.

The <num> variable is a loopback interface or virtual interface number.

ARP parameter configuration

Address Resolution Protocol (ARP) is a standard IP protocol that enables an IP Layer 3 Switch to obtain the MAC address of another device interface when the Layer 3 Switch knows the IP address of the interface. ARP is enabled by default and cannot be disabled.

NOTE

Brocade Layer 2 Switches also support ARP. The description in [“How ARP works”](#) also applies to ARP on Brocade Layer 2 Switches. However, the configuration options described later in this section apply only to Layer 3 Switches, not to Layer 2 Switches.

How ARP works

A Layer 3 Switch needs to know a destination MAC address when forwarding traffic, because the Layer 3 Switch encapsulates the IP packet in a Layer 2 packet (MAC layer packet) and sends the Layer 2 packet to a MAC interface on a device directly attached to the Layer 3 Switch. The device can be the packet final destination or the next-hop router toward the destination.

The Layer 3 Switch encapsulates IP packets in Layer 2 packets regardless of whether the ultimate destination is locally attached or is multiple router hops away. Since the Layer 3 Switch IP route table and IP forwarding cache contain IP address information but not MAC address information, the Layer 3 Switch cannot forward IP packets based solely on the information in the route table or forwarding cache. The Layer 3 Switch needs to know the MAC address that corresponds with the IP address of either the packet locally attached destination or the next-hop router that leads to the destination.

For example, to forward a packet whose destination is multiple router hops away, the Layer 3 Switch must send the packet to the next-hop router toward its destination, or to a default route or default network route if the IP route table does not contain a route to the packet destination. In each case, the Layer 3 Switch must encapsulate the packet and address it to the MAC address of a locally attached device, the next-hop router toward the IP packet destination.

To obtain the MAC address required for forwarding a datagram, the Layer 3 Switch does the following:

- First, the Layer 3 Switch looks in the ARP cache (not the static ARP table) for an entry that lists the MAC address for the IP address. The ARP cache maps IP addresses to MAC addresses. The cache also lists the port attached to the device and, if the entry is dynamic, the age of the entry. A dynamic ARP entry enters the cache when the Layer 3 Switch receives an ARP reply or receives an ARP request (which contains the sender IP address and MAC address). A static entry enters the ARP cache from the static ARP table (which is a separate table) when the interface for the entry comes up.

To ensure the accuracy of the ARP cache, each dynamic entry has its own age timer. The timer is reset to zero each time the Layer 3 Switch receives an ARP reply or ARP request containing the IP address and MAC address of the entry. If a dynamic entry reaches its maximum allowable age, the entry times out and the software removes the entry from the table. Static entries do not age out and can be removed only by you.

- If the ARP cache does not contain an entry for the destination IP address, the Layer 3 Switch broadcasts an ARP request out all its IP interfaces. The ARP request contains the IP address of the destination. If the device with the IP address is directly attached to the Layer 3 Switch, the device sends an ARP response containing its MAC address. The response is a unicast packet addressed directly to the Layer 3 Switch. The Layer 3 Switch places the information from the ARP response into the ARP cache.

ARP requests contain the IP address and MAC address of the sender, so all devices that receive the request learn the MAC address and IP address of the sender and can update their own ARP caches accordingly.

NOTE

The ARP request broadcast is a MAC broadcast, which means the broadcast goes only to devices that are directly attached to the Layer 3 Switch. A MAC broadcast is not routed to other networks. However, some routers, including Brocade Layer 3 Switches, can be configured to reply to ARP requests from one network on behalf of devices on another network. Refer to [“Enabling proxy ARP”](#) on page 983.

NOTE

If the router receives an ARP request packet that it is unable to deliver to the final destination because of the ARP timeout and no ARP response is received (the Layer 3 Switch knows of no route to the destination address), the router sends an ICMP Host Unreachable message to the source.

Rate limiting ARP packets

You can limit the number of ARP packets the Brocade device accepts during each second. By default, the software does not limit the number of ARP packets the device can receive. Since the device sends ARP packets to the CPU for processing, if a device in a busy network receives a high number of ARP packets in a short period of time, some CPU processing might be deferred while the CPU processes the ARP packets.

To prevent the CPU from becoming flooded by ARP packets in a busy network, you can restrict the number of ARP packets the device will accept each second. When you configure an ARP rate limit, the device accepts up to the maximum number of packets you specify, but drops additional ARP packets received during the one-second interval. When a new one-second interval starts, the counter restarts at zero, so the device again accepts up to the maximum number of ARP packets you specified, but drops additional packets received within the interval.

To limit the number of ARP packets the device will accept each second, enter the **rate-limit-arp** command at the global CONFIG level of the CLI.

```
Brocade(config)# rate-limit-arp 100
```

This command configures the device to accept up to 100 ARP packets each second. If the device receives more than 100 ARP packets during a one-second interval, the device drops the additional ARP packets during the remainder of that one-second interval.

Syntax: [no] **rate-limit-arp** <num>

The <num> parameter specifies the number of ARP packets and can be from 0 through 100. If you specify 0, the device will not accept any ARP packets.

NOTE

If you want to change a previously configured the ARP rate limiting policy, you must remove the previously configured policy using the **no rate-limit-arp** <num> command before entering the new policy.

Changing the ARP aging period

When the Layer 3 Switch places an entry in the ARP cache, the Layer 3 Switch also starts an aging timer for the entry. The aging timer ensures that the ARP cache does not retain learned entries that are no longer valid. An entry can become invalid when the device with the MAC address of the entry is no longer on the network.

The ARP age affects dynamic (learned) entries only, not static entries. The default ARP age is ten minutes. On Layer 3 Switches, you can change the ARP age to a value from 0 through 240 minutes. You cannot change the ARP age on Layer 2 Switches. If you set the ARP age to zero, aging is disabled and entries do not age out.

To globally change the ARP aging parameter to 20 minutes, enter the **ip arp-age** command.

```
Brocade(config)# ip arp-age 20
```

Syntax: **ip arp-age** <num>

The <num> parameter specifies the number of minutes and can be from 0 through 240. The default is 10. If you specify 0, aging is disabled.

To override the globally configured IP ARP age on an individual interface, enter a command such as the following at the interface configuration level.

```
Brocade(config-if-e1000-1/1)# ip arp-age 30
```

Syntax: [no] **ip arp-age** <num>

The <num> parameter specifies the number of minutes and can be from 0 through 240. The default is the globally configured value, which is 10 minutes by default. If you specify 0, aging is disabled.

Enabling proxy ARP

Proxy ARP allows a Layer 3 Switch to answer ARP requests from devices on one network on behalf of devices in another network. Since ARP requests are MAC-layer broadcasts, they reach only the devices that are directly connected to the sender of the ARP request. Thus, ARP requests do not cross routers.

For example, if Proxy ARP is enabled on a Layer 3 Switch connected to two subnets, 10.10.10.0/24 and 20.20.20.0/24, the Layer 3 Switch can respond to an ARP request from 10.10.10.69 for the MAC address of the device with IP address 20.20.20.69. In standard ARP, a request from a device in the 10.10.10.0/24 subnet cannot reach a device in the 20.20.20.0 subnet if the subnets are on different network cables, and thus is not answered.

NOTE

An ARP request from one subnet can reach another subnet when both subnets are on the same physical segment (Ethernet cable), because MAC-layer broadcasts reach all the devices on the segment.

Proxy ARP is disabled by default on Brocade Layer 3 Switches. This feature is not supported on Brocade Layer 2 Switches.

You can enable proxy ARP at the Interface level, as well as at the Global CONFIG level, of the CLI.

NOTE

Configuring proxy ARP at the Interface level overrides the global configuration.

Enabling proxy ARP globally

To enable IP proxy ARP on a global basis, enter the **ip proxy-arp** command.

```
Brocade(config)# ip proxy-arp
```

To again disable IP proxy ARP on a global basis, enter the **no ip proxy-arp** command.

```
Brocade(config)# no ip proxy-arp
```

Syntax: [no] ip proxy-arp

Enabling IP ARP on an interface

NOTE

Configuring proxy ARP at the Interface level overrides the global configuration.

To enable IP proxy ARP on an interface, enter the following commands.

```
Brocade(config)# interface ethernet 5
Brocade(config-if-e1000-5)# ip proxy-arp enable
```

To again disable IP proxy ARP on an interface, enter the following command.

```
Brocade(config)# interface ethernet 5
Brocade(config-if-e1000-5)# ip proxy-arp disable
```

Syntax: [no] ip proxy-arp enable | disable

Enabling local proxy ARP

Brocade devices support Proxy Address Resolution Protocol (**Proxy ARP**), a feature that enables router ports to respond to ARP requests for subnets it can reach. However, router ports will not respond to ARP requests for IP addresses in the same subnet as the incoming ports, unless Local Proxy ARP per IP interface is enabled. **Local Proxy ARP** enables router ports to reply to ARP requests for IP addresses within the same subnet and to forward all traffic between hosts in the subnet.

When Local Proxy ARP is enabled on a router port, the port will respond to ARP requests for IP addresses within the same subnet, if it has ARP entries for the destination IP addresses in the ARP cache. If it does not have ARP entries for the IP addresses, the port will attempt to resolve them by broadcasting its own ARP requests.

Local Proxy ARP is disabled by default. To use Local Proxy ARP, Proxy ARP (**ip proxy-arp** command) must be enabled globally on the Brocade device. You can enter the CLI command to enable Local Proxy ARP even though Proxy ARP is not enabled, however, the configuration will not take effect until you enable Proxy ARP.

Use the **show run** command to view the ports on which Local Proxy ARP is enabled.

To enable Local Proxy ARP, enter commands such as the following.

```
Brocade(config)# interface ethernet 4
Brocade(config-if-e1000-4)# ip local-proxy-arp
```

Syntax: [no] **ip local-proxy-arp**

Use the **no** form of the command to disable Local Proxy ARP.

Creating static ARP entries

Brocade Layer 3 Switches have a static ARP table, in addition to the regular ARP cache. The static ARP table contains entries that you configure.

Static entries are useful in cases where you want to pre-configure an entry for a device that is not connected to the Layer 3 Switch, or you want to prevent a particular entry from aging out. The software removes a dynamic entry from the ARP cache if the ARP aging interval expires before the entry is refreshed. Static entries do not age out, regardless of whether the Brocade device receives an ARP request from the device that has the entry address.

NOTE

You cannot create static ARP entries on a Layer 2 Switch.

The maximum number of static ARP entries you can configure depends on the software version running on the device. Refer to [“Changing the maximum number of entries the static ARP table can hold”](#) on page 986.

To display the ARP cache and static ARP table, refer to the following:

- To display the ARP table, refer to [“Displaying the ARP cache”](#) on page 1070.
- To display the static ARP table, refer to [“Displaying the static ARP table”](#) on page 1072.

To create a static ARP entry, enter a command such as the following.

```
Brocade(config)# arp 1 192.53.4.2 1245.7654.2348 ethernet 1/2
```

Syntax: **arp** <num> <ip-addr> <mac-addr> **ethernet** <port>

The <num> parameter specifies the entry number. You can specify a number from 1 up to the maximum number of static entries allowed on the device.

The <ip-addr> parameter specifies the IP address of the device that has the MAC address of the entry.

The <mac-addr> parameter specifies the MAC address of the entry.

The **ethernet** <port> command specifies the port number attached to the device that has the MAC address of the entry. Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Changing the maximum number of entries the static ARP table can hold

[Table 168](#) on page 986 lists the default maximum and configurable maximum number of entries in the static ARP table that are supported on a Brocade Layer 3 Switch. If you need to change the maximum number of entries supported on a Layer 3 Switch, use the method described in this section.

NOTE

The basic procedure for changing the static ARP table size is the same as the procedure for changing other configurable cache or table sizes. Refer to the section [“Displaying system parameter default values”](#) on page 578.

To increase the maximum number of static ARP table entries you can configure on a Brocade Layer 3 Switch, enter commands such as the following at the global CONFIG level of the CLI.

```
Brocade(config)# system-max ip-static-arp 1000
Brocade(config)# write memory
Brocade(config)# end
Brocade# reload
```

NOTE

You must save the configuration to the startup-config file and reload the software after changing the static ARP table size to place the change into effect.

Syntax: `system-max ip-static-arp <num>`

The `<num>` parameter indicates the maximum number of static ARP entries and can be within one of the ranges shown in [Table 168](#), depending on the software version running on the device.

TABLE 168 Static ARP entry support

Default maximum	Configurable minimum	Configurable maximum
FastIron X Series and Brocade FCX Series devices		
512	512	6000
ICX 6450 devices		
256	64	1024

Configuring forwarding parameters

The following configurable parameters control the forwarding behavior of Brocade Layer 3 Switches:

- Time-To-Live (TTL) threshold
- Forwarding of directed broadcasts
- Forwarding of source-routed packets
- Ones-based and zero-based broadcasts

All these parameters are global and thus affect all IP interfaces configured on the Layer 3 Switch.

To configure these parameters, use the procedures in the following sections.

Changing the TTL threshold

The time to live (TTL) threshold prevents routing loops by specifying the maximum number of router hops an IP packet originated by the Layer 3 Switch can travel through. Each device capable of forwarding IP that receives the packet decrements (decreases) the packet TTL by one. If a device receives a packet with a TTL of 1 and reduces the TTL to zero, the device drops the packet.

The default TTL is 64. You can change the TTL to a value from 1 through 255.

To modify the TTL threshold to 25, enter the **ip ttl** command.

```
Brocade(config)# ip ttl 25
```

Syntax: **ip ttl** <1-255>

Enabling forwarding of directed broadcasts

A directed broadcast is an IP broadcast to all devices within a single directly-attached network or subnet. A net-directed broadcast goes to all devices on a given network. A subnet-directed broadcast goes to all devices within a given subnet.

NOTE

A less common type, the all-subnets broadcast, goes to all directly-attached subnets. Forwarding for this broadcast type also is supported, but most networks use IP multicasting instead of all-subnet broadcasting.

Forwarding for all types of IP directed broadcasts is disabled by default. You can enable forwarding for all types if needed. You cannot enable forwarding for specific broadcast types.

To enable forwarding of IP directed broadcasts, enter the **ip directed-broadcast** command.

```
Brocade(config)# ip directed-broadcast
```

Syntax: **[no] ip directed-broadcast**

Brocade software makes the forwarding decision based on the router's knowledge of the destination network prefix. Routers cannot determine that a message is unicast or directed broadcast apart from the destination network prefix. The decision to forward or not forward the message is by definition only possible in the last hop router.

To disable the directed broadcasts, enter the **no ip directed-broadcast** command in the CONFIG mode.

```
Brocade(config)# no ip directed-broadcast
```

To enable directed broadcasts on an individual interface instead of globally for all interfaces, enter commands such as the following.

```
Brocade(config)# interface ethernet 1/1
Brocade(config-if-1/1)# ip directed-broadcast
```

Syntax: **[no] ip directed-broadcast**

Disabling forwarding of IP source-routed packets

A source-routed packet specifies the exact router path for the packet. The packet specifies the path by listing the IP addresses of the router interfaces through which the packet must pass on its way to the destination. The Layer 3 Switch supports both types of IP source routing:

- Strict source routing – requires the packet to pass through only the listed routers. If the Layer 3 Switch receives a strict source-routed packet but cannot reach the next hop interface specified by the packet, the Layer 3 Switch discards the packet and sends an ICMP Source-Route-Failure message to the sender.

NOTE

The Layer 3 Switch allows you to disable sending of the Source-Route-Failure messages. Refer to [“Disabling ICMP messages”](#) on page 989.

- Loose source routing – requires that the packet pass through all of the listed routers but also allows the packet to travel through other routers, which are not listed in the packet.

The Layer 3 Switch forwards both types of source-routed packets by default. To disable the feature, use either of the following methods. You cannot enable or disable strict or loose source routing separately.

To disable forwarding of IP source-routed packets, enter the **no ip source-route** command.

```
Brocade(config)# no ip source-route
```

Syntax: [no] ip source-route

To re-enable forwarding of source-routed packets, enter the **ip source-route** command.

```
Brocade(config)# ip source-route
```

Enabling support for zero-based IP subnet broadcasts

By default, the Layer 3 Switch treats IP packets with all ones in the host portion of the address as IP broadcast packets. For example, the Layer 3 Switch treats IP packets with 209.157.22.255/24 as the destination IP address as IP broadcast packets and forwards the packets to all IP hosts within the 209.157.22.x subnet (except the host that sent the broadcast packet to the Layer 3 Switch).

Most IP hosts are configured to receive IP subnet broadcast packets with all ones in the host portion of the address. However, some older IP hosts instead expect IP subnet broadcast packets that have all zeros instead of all ones in the host portion of the address. To accommodate this type of host, you can enable the Layer 3 Switch to treat IP packets with all zeros in the host portion of the destination IP address as broadcast packets.

NOTE

When you enable the Layer 3 Switch for zero-based subnet broadcasts, the Layer 3 Switch still treats IP packets with all ones the host portion as IP subnet broadcasts too. Thus, the Layer 3 Switch can be configured to support all ones only (the default) or all ones **and** all zeroes.

NOTE

This feature applies only to IP subnet broadcasts, not to local network broadcasts. The local network broadcast address is still expected to be all ones.

To enable the Layer 3 Switch for zero-based IP subnet broadcasts in addition to ones-based IP subnet broadcasts, enter the following command.

```

Brocade(config)# ip broadcast-zero
Brocade(config)# write memory
Brocade(config)# end
Brocade# reload

```

NOTE

You must save the configuration and reload the software to place this configuration change into effect.

Syntax: [no] ip broadcast-zero

Disabling ICMP messages

Brocade devices are enabled to reply to ICMP echo messages and send ICMP Destination Unreachable messages by default.

You can selectively disable the following types of Internet Control Message Protocol (ICMP) messages:

- **Echo messages (ping messages)** – The Layer 3 Switch replies to IP pings from other IP devices.
- **Destination Unreachable messages** – If the Layer 3 Switch receives an IP packet that it cannot deliver to its destination, the Layer 3 Switch discards the packet and sends a message back to the device that sent the packet to the Layer 3 Switch. The message informs the device that the destination cannot be reached by the Layer 3 Switch.

Disabling replies to broadcast ping requests

By default, Brocade devices are enabled to respond to broadcast ICMP echo packets, which are ping requests.

To disable response to broadcast ICMP echo packets (ping requests), enter the following command.

```
Brocade(config)# no ip icmp echo broadcast-request
```

Syntax: [no] ip icmp echo broadcast-request

If you need to re-enable response to ping requests, enter the following command.

```
Brocade(config)# ip icmp echo broadcast-request
```

Disabling ICMP destination unreachable messages

By default, when a Brocade device receives an IP packet that the device cannot deliver, the device sends an ICMP Unreachable message back to the host that sent the packet. You can selectively disable a Brocade device response to the following types of ICMP Unreachable messages:

- **Administration** – The packet was dropped by the Brocade device due to a filter or ACL configured on the device.
- **Fragmentation-needed** – The packet has the Do not Fragment bit set in the IP Flag field, but the Brocade device cannot forward the packet without fragmenting it.
- **Host** – The destination network or subnet of the packet is directly connected to the Brocade device, but the host specified in the destination IP address of the packet is not on the network.
- **Port** – The destination host does not have the destination TCP or UDP port specified in the packet. In this case, the host sends the ICMP Port Unreachable message to the Brocade device, which in turn sends the message to the host that sent the packet.

- **Protocol** – The TCP or UDP protocol on the destination host is not running. This message is different from the Port Unreachable message, which indicates that the protocol is running on the host but the requested protocol port is unavailable.
- **Source-route-failure** – The device received a source-routed packet but cannot locate the next-hop IP address indicated in the packet Source-Route option.

You can disable the Brocade device from sending these types of ICMP messages on an individual basis. To do so, use the following CLI method.

NOTE

Disabling an ICMP Unreachable message type does not change the Brocade device ability to forward packets. Disabling ICMP Unreachable messages prevents the device from generating or forwarding the Unreachable messages.

To disable all ICMP Unreachable messages, enter the **no ip icmp unreachable** command.

```
Brocade(config)# no ip icmp unreachable
```

Syntax: [no] ip icmp unreachable [host | protocol | administration | fragmentation-needed | port | source-route-fail]

- If you enter the command without specifying a message type (as in the example above), all types of ICMP Unreachable messages listed above are disabled. If you want to disable only specific types of ICMP Unreachable messages, you can specify the message type. To disable more than one type of ICMP message, enter the **no ip icmp unreachable** command for each messages type.
- The **administration** parameter disables ICMP Unreachable (caused by Administration action) messages.
- The **fragmentation-needed** parameter disables ICMP Fragmentation-Needed But Do not-Fragment Bit Set messages.
- The **host** parameter disables ICMP Host Unreachable messages.
- The **port** parameter disables ICMP Port Unreachable messages.
- The **protocol** parameter disables ICMP Protocol Unreachable messages.
- The **source-route-fail** parameter disables ICMP Unreachable (caused by Source-Route-Failure) messages.

To disable ICMP Host Unreachable messages but leave the other types of ICMP Unreachable messages enabled, enter the following commands instead of the command shown above.

```
Brocade(config)# no ip icmp unreachable host
```

If you have disabled all ICMP Unreachable message types but you want to re-enable certain types, for example ICMP Host Unreachable messages, you can do so by entering the following command.

```
Brocade(config)# ip icmp unreachable host
```

Disabling ICMP Redirect Messages

You can disable or re-enable ICMP redirect messages. By default, a Brocade Layer 3 Switch sends an ICMP redirect message to the source of a misdirected packet in addition to forwarding the packet to the appropriate router. You can disable ICMP redirect messages on a global basis or on an individual port basis.

NOTE

FESX and FSX devices do not generate ICMP redirect and network unreachable messages.

NOTE

The device forwards misdirected traffic to the appropriate router, even if you disable the redirect messages.

To disable ICMP redirect messages globally, enter the following command at the global CONFIG level of the CLI:

```
Brocade(config)# no ip icmp redirect
```

Syntax: [no] ip icmp redirects

To disable ICMP redirect messages on a specific interface, enter the following command at the configuration level for the interface:

```
Brocade(config)# interface ethernet 3/11
Brocade(config-if-e1000-3/11)# no ip redirect
```

Syntax: [no] ip redirect

Static routes configuration

The IP route table can receive routes from the following sources:

- **Directly-connected networks** – When you add an IP interface, the Layer 3 Switch automatically creates a route for the network the interface is in.
- **RIP** – If RIP is enabled, the Layer 3 Switch can learn about routes from the advertisements other RIP routers send to the Layer 3 Switch. If the route has a lower administrative distance than any other routes from different sources to the same destination, the Layer 3 Switch places the route in the IP route table.
- **OSPF** – Refer to RIP, but substitute “OSPF” for “RIP”.
- **BGP4** – Refer to RIP, but substitute “BGP4” for “RIP”.
- **Default network route** – A statically configured default route that the Layer 3 Switch uses if other default routes to the destination are not available. Refer to [“Configuring a default network route”](#) on page 1000.
- **Statically configured route** – You can add routes directly to the route table. When you add a route to the IP route table, you are creating a static IP route. This section describes how to add static routes to the IP route table.

Static route types

You can configure the following types of static IP routes:

- **Standard** – the static route consists of the destination network address and network mask, and the IP address of the next-hop gateway. You can configure multiple standard static routes with the same metric for load sharing or with different metrics to provide a primary route and backup routes.
- **Interface-based** – the static route consists of the destination network address and network mask, and the Layer 3 Switch interface through which you want the Layer 3 Switch to send traffic for the route. Typically, this type of static route is for directly attached destination networks.

- **Null** – the static route consists of the destination network address and network mask, and the “null0” parameter. Typically, the null route is configured as a backup route for discarding traffic if the primary route is unavailable.

Static IP route parameters

When you configure a static IP route, you must specify the following parameters:

- The IP address and network mask for the route destination network.
- The route path, which can be one of the following:
 - The IP address of a next-hop gateway
 - An Ethernet port
 - A virtual interface (a routing interface used by VLANs for routing Layer 3 protocol traffic among one another)
 - A “null” interface. The Layer 3 Switch drops traffic forwarded to the null interface.

You also can specify the following optional parameters:

- The metric for the route – The value the Layer 3 Switch uses when comparing this route to other routes in the IP route table to the same destination. The metric applies only to routes that the Layer 3 Switch has already placed in the IP route table. The default metric for static IP routes is 1.
- The administrative distance for the route – The value that the Layer 3 Switch uses to compare this route with routes from other route sources to the same destination before placing a route in the IP route table. This parameter does not apply to routes that are already in the IP route table. The default administrative distance for static IP routes is 1.

The default metric and administrative distance values ensure that the Layer 3 Switch always prefers static IP routes over routes from other sources to the same destination.

Multiple static routes to the same destination provide load sharing and redundancy

You can add multiple static routes for the same destination network to provide one or more of the following benefits:

- **IP load balancing** – When you add multiple IP static routes for the same destination to different next-hop gateways, and the routes each have the same metric and administrative distance, the Layer 3 Switch can load balance traffic to the routes’ destination. For information about IP load balancing, refer to [“Configuring IP load sharing”](#) on page 1001.
- **Path redundancy** – When you add multiple static IP routes for the same destination, but give the routes different metrics or administrative distances, the Layer 3 Switch uses the route with the lowest administrative distance by default, but uses another route to the same destination if the first route becomes unavailable.

Refer to the following sections for examples and configuration information:

- [“Configuring load balancing and redundancy using multiple static routes to the same destination”](#) on page 996
- [“Configuring standard static IP routes and interface or null static routes to the same destination”](#) on page 997

Static route states follow port states

IP static routes remain in the IP route table only so long as the port or virtual interface used by the route is available. If the port or virtual routing interface becomes unavailable, the software removes the static route from the IP route table. If the port or virtual routing interface becomes available again later, the software adds the route back to the route table.

This feature allows the Layer 3 Switch to adjust to changes in network topology. The Layer 3 Switch does not continue trying to use routes on unavailable paths but instead uses routes only when their paths are available.

Figure 113 shows an example of a network containing a static route. The static route is configured on Switch A, as shown in the CLI example following the figure.

FIGURE 113 Example of a static route

The following command configures a static route to 207.95.7.0, using 207.95.6.157 as the next-hop gateway.

```
Brocade(config)# ip route 207.95.7.0/24 207.95.6.157
```

When you configure a static IP route, you specify the destination address for the route and the next-hop gateway or Layer 3 Switch interface through which the Layer 3 Switch can reach the route. The Layer 3 Switch adds the route to the IP route table. In this case, Switch A knows that 207.95.6.157 is reachable through port 1/2, and also assumes that local interfaces within that subnet are on the same port. Switch A deduces that IP interface 207.95.7.188 is also on port 1/2.

The software automatically removes a static IP route from the IP route table if the port used by that route becomes unavailable. When the port becomes available again, the software automatically re-adds the route to the IP route table.

Configuring a static IP route

To configure an IP static route with a destination address of 192.0.0.0 255.0.0.0 and a next-hop router IP address of 195.1.1.1, enter a command such as the following.

```
Brocade(config)# ip route 192.0.0.0 255.0.0.0 195.1.1.1
```

To configure a static IP route with an Ethernet port instead of a next-hop address, enter a command such as the following.

```
Brocade(config)# ip route 192.128.2.69 255.255.255.0 ethernet 4/1
```

The command in the previous example configures a static IP route for destination network 192.128.2.69/24. Since an Ethernet port is specified instead of a gateway IP address as the next hop, the Layer 3 Switch always forwards traffic for the 192.128.2.69/24 network to port 4/1. The command in the following example configures an IP static route that uses virtual interface 3 as its next hop.

```
Brocade(config)# ip route 192.128.2.71 255.255.255.0 ve 3
```

The command in the following example configures an IP static route that uses port 2/2 as its next hop.

```
Brocade(config)# ip route 192.128.2.73 255.255.255.0 ethernet 2/2
```

Syntax: **ip route** *<dest-ip-addr>* *<dest-mask>*
 <next-hop-ip-addr> |
 ethernet [*<slotnum>/<portnum>*] | **ve** *<num>*
 [*<metric>*] [**distance** *<num>*]

or

Syntax: **ip route** *<dest-ip-addr>/<mask-bits>*
 <next-hop-ip-addr> |
 ethernet [*<slotnum>/<portnum>*] | **ve** *<num>*
 [*<metric>*] [**distance** *<num>*]

The *<dest-ip-addr>* is the route destination. The *<dest-mask>* is the network mask for the route destination IP address. Alternatively, you can specify the network mask information by entering a forward slash followed by the number of bits in the network mask. For example, you can enter 192.0.0.0 255.255.255.0 as 192.0.0.0/.24.

The *<next-hop-ip-addr>* is the IP address of the next-hop router (gateway) for the route.

If you do not want to specify a next-hop IP address, you can instead specify a port or interface number on the Layer 3 Switch. The *<num>* parameter is a virtual interface number. If you instead specify an Ethernet port, the *<portnum>* is the port number (including the slot number, if you are configuring a Chassis device). In this case, the Layer 3 Switch forwards packets destined for the static route destination network to the specified interface. Conceptually, this feature makes the destination network like a directly connected network, associated with a specific Layer 3 Switch interface.

NOTE

The port or virtual interface you use for the static route next hop must have at least one IP address configured on it. The address does not need to be in the same subnet as the destination network.

The *<metric>* parameter can be a number from 1 through 16. The default is 1.

NOTE

If you specify 16, RIP considers the metric to be infinite and thus also considers the route to be unreachable.

The **distance** *<num>* parameter specifies the administrative distance of the route. When comparing otherwise equal routes to a destination, the Layer 3 Switch prefers lower administrative distances over higher ones, so make sure you use a low value for your default route. The default is 1.

NOTE

The Layer 3 Switch will replace the static route if the it receives a route with a lower administrative distance. Refer to [“Administrative distance”](#) on page 1265 for a list of the default administrative distances for all types of routes.

NOTE

You can also assign the default router as the destination by entering 0.0.0.0 0.0.0.0 xxx.xxx.xxx.xxx.

Configuring a “Null” route

You can configure the Layer 3 Switch to drop IP packets to a specific network or host address by configuring a “null” (sometimes called “null0”) static route for the address. When the Layer 3 Switch receives a packet destined for the address, the Layer 3 Switch drops the packet instead of forwarding it.

To configure a null static route, use the following CLI method.

To configure a null static route to drop packets destined for network 209.157.22.x, enter the following commands.

```
Brocade(config)# ip route 209.157.22.0 255.255.255.0 null0
Brocade(config)# write memory
```

Syntax: `ip route <ip-addr> <ip-mask> null0 [<metric>] [distance <num>]`

or

Syntax: `ip route <ip-addr>/<mask-bits> null0 [<metric>] [distance <num>]`

To display the maximum value for your device, enter the **show default values** command. The maximum number of static IP routes the system can hold is listed in the ip-static-route row in the System Parameters section of the display. To change the maximum value, use the **system-max ip-static-route <num>** command at the global CONFIG level.

The `<ip-addr>` parameter specifies the network or host address. The Layer 3 Switch will drop packets that contain this address in the destination field instead of forwarding them.

The `<ip-mask>` parameter specifies the network mask. Ones are significant bits and zeros allow any value. For example, the mask 255.255.255.0 matches on all hosts within the Class C subnet address specified by `<ip-addr>`. Alternatively, you can specify the number of bits in the network mask. For example, you can enter 209.157.22.0/24 instead of 209.157.22.0 255.255.255.0.

The **null0** parameter indicates that this is a null route. You must specify this parameter to make this a null route.

The `<metric>` parameter adds a cost to the route. You can specify from 1 through 16. The default is 1.

The distance `<num>` parameter configures the administrative distance for the route. You can specify a value from 1 through 255. The default is 1. The value 255 makes the route unusable.

NOTE

The last two parameters are optional and do not affect the null route, unless you configure the administrative distance to be 255. In this case, the route is not used and the traffic might be forwarded instead of dropped.

Configuring load balancing and redundancy using multiple static routes to the same destination

You can configure multiple static IP routes to the same destination, for the following benefits:

- **IP load sharing** – If you configure more than one static route to the same destination, and the routes have different next-hop gateways but have the same metrics, the Layer 3 Switch load balances among the routes using basic round-robin. For example, if you configure two static routes with the same metrics but to different gateways, the Layer 3 Switch alternates between the two routes. For information about IP load balancing, refer to [“Configuring IP load sharing”](#) on page 1001.
- **Backup Routes** – If you configure multiple static IP routes to the same destination, but give the routes different next-hop gateways and different metrics, the Layer 3 Switch will always use the route with the lowest metric. If this route becomes unavailable, the Layer 3 Switch will fail over to the static route with the next-lowest metric, and so on.

NOTE

You also can bias the Layer 3 Switch to select one of the routes by configuring them with different administrative distances. However, make sure you do not give a static route a higher administrative distance than other types of routes, unless you want those other types to be preferred over the static route. For a list of the default administrative distances, refer to [“Administrative distance”](#) on page 1265.

The steps for configuring the static routes are the same as described in the previous section. The following sections provide examples.

To configure multiple static IP routes, enter commands such as the following.

```
Brocade(config)# ip route 192.128.2.69 255.255.255.0 209.157.22.1
Brocade(config)# ip route 192.128.2.69 255.255.255.0 192.111.10.1
```

The commands in the previous example configure two static IP routes. The routes go to different next-hop gateways but have the same metrics. These commands use the default metric value (1), so the metric is not specified. These static routes are used for load sharing among the next-hop gateways.

The following commands configure static IP routes to the same destination, but with different metrics. The route with the lowest metric is used by default. The other routes are backups in case the first route becomes unavailable. The Layer 3 Switch uses the route with the lowest metric if the route is available.

```
Brocade(config)# ip route 192.128.2.69 255.255.255.0 209.157.22.1
Brocade(config)# ip route 192.128.2.69 255.255.255.0 192.111.10.1 2
Brocade(config)# ip route 192.128.2.69 255.255.255.0 201.1.1.1 3
```

In this example, each static route has a different metric. The metric is not specified for the first route, so the default (1) is used. A metric is specified for the second and third static IP routes. The second route has a metric of two and the third route has a metric of 3. Thus, the second route is used only if the first route (which has a metric of 1) becomes unavailable. Likewise, the third route is used only if the first and second routes (which have lower metrics) are both unavailable.

For complete syntax information, refer to [“Configuring a static IP route”](#) on page 993.

Configuring standard static IP routes and interface or null static routes to the same destination

You can configure a null0 or interface-based static route to a destination and also configure a normal static route to the same destination, so long as the route metrics are different.

When the Layer 3 Switch has multiple routes to the same destination, the Layer 3 Switch always prefers the route with the lowest metric. Generally, when you configure a static route to a destination network, you assign the route a low metric so that the Layer 3 Switch prefers the static route over other routes to the destination.

This feature is especially useful for the following configurations. These are not the only allowed configurations but they are typical uses of this enhancement:

- When you want to ensure that if a given destination network is unavailable, the Layer 3 Switch drops (forwards to the null interface) traffic for that network instead of using alternate paths to route the traffic. In this case, assign the normal static route to the destination network a lower metric than the null route.
- When you want to use a specific interface by default to route traffic to a given destination network, but want to allow the Layer 3 Switch to use other interfaces to reach the destination network if the path that uses the default interface becomes unavailable. In this case, give the interface route a lower metric than the normal static route.

NOTE

You cannot add a null or interface-based static route to a network if there is already a static route of any type with the same metric you specify for the null or interface-based route.

Figure 114 shows an example of two static routes configured for the same destination network. In this example, one of the routes is a standard static route and has a metric of 1. The other static route is a null route and has a higher metric than the standard static route. The Layer 3 Switch always prefers the static route with the lower metric. In this example, the Layer 3 Switch always uses the standard static route for traffic to destination network 192.168.7.0/24, unless that route becomes unavailable, in which case the Layer 3 Switch sends traffic to the null route instead.

FIGURE 114 Standard and null static routes to the same destination network

Configuring IP parameters – Layer 3 Switches

Two static routes to 192.168.7.0/24:

--Standard static route through gateway 192.168.6.157, with metric 1

--Null route, with metric 2

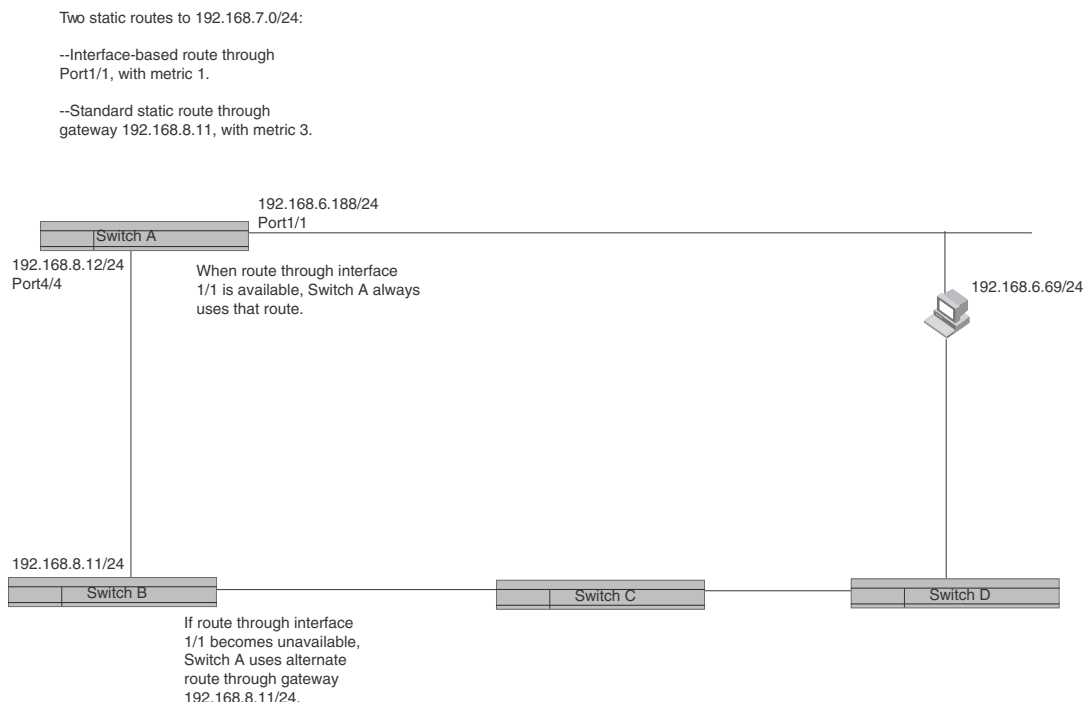

Figure 115 shows another example of two static routes. In this example, a standard static route and an interface-based static route are configured for destination network 192.168.6.0/24. The interface-based static route has a lower metric than the standard static route. As a result, the Layer 3 Switch always prefers the interface-based route when the route is available. However, if the interface-based route becomes unavailable, the Layer 3 Switch still forwards the traffic toward the destination using an alternate route through gateway 192.168.8.11/24.

FIGURE 115 Standard and interface routes to the same destination network

To configure a standard static IP route and a null route to the same network as shown in [Figure 114](#) on page 997, enter commands such as the following.

```
Brocade(config)# ip route 192.168.7.0/24 192.168.6.157/24 1
Brocade(config)# ip route 192.168.7.0/24 null0 3
```

The first command configures a standard static route, which includes specification of the next-hop gateway. The command also gives the standard static route a metric of 1, which causes the Layer 3 Switch to always prefer this route when the route is available.

The second command configures another static route for the same destination network, but the second route is a null route. The metric for the null route is 3, which is higher than the metric for the standard static route. If the standard static route is unavailable, the software uses the null route.

For complete syntax information, refer to [“Configuring a static IP route”](#) on page 993.

To configure a standard static route and an interface-based route to the same destination, enter commands such as the following.

```
Brocade(config)# ip route 192.168.6.0/24 ethernet 1/1 1
Brocade(config)# ip route 192.168.6.0/24 192.168.8.11/24 3
```

The first command configured an interface-based static route through Ethernet port 1/1. The command assigns a metric of 1 to this route, causing the Layer 3 Switch to always prefer this route when it is available. If the route becomes unavailable, the Layer 3 Switch uses an alternate route through the next-hop gateway 192.168.8.11/24.

Configuring a default network route

The Layer 3 Switch enables you to specify a candidate default route without the need to specify the next hop gateway. If the IP route table does not contain an explicit default route (for example, 0.0.0.0/0) or propagate an explicit default route through routing protocols, the software can use the default network route as a default route instead.

When the software uses the default network route, it also uses the default network route's next hop gateway as the gateway of last resort.

This feature is especially useful in environments where network topology changes can make the next hop gateway unreachable. This feature allows the Layer 3 Switch to perform default routing even if the default network route's default gateway changes.

The feature thus differs from standard default routes. When you configure a standard default route, you also specify the next hop gateway. If a topology change makes the gateway unreachable, the default route becomes unusable.

For example, if you configure 10.10.10.0/24 as a candidate default network route, if the IP route table does not contain an explicit default route (0.0.0.0/0), the software uses the default network route and automatically uses that route's next hop gateway as the default gateway. If a topology change occurs and as a result the default network route's next hop gateway changes, the software can still use the default network route. To configure a default network route, use the following CLI method.

If you configure more than one default network route, the Layer 3 Switch uses the following algorithm to select one of the routes.

1. Use the route with the lowest administrative distance.
2. If the administrative distances are equal:
 - Are the routes from different routing protocols (RIP, OSPF, or BGP4)? If so, use the route with the lowest IP address.
 - If the routes are from the same routing protocol, use the route with the best metric. The meaning of “best” metric depends on the routing protocol:
 - **RIP** – The metric is the number of hops (additional routers) to the destination. The best route is the route with the fewest hops.
 - **OSPF** – The metric is the path cost associated with the route. The path cost does not indicate the number of hops but is instead a numeric value associated with each route. The best route is the route with the lowest path cost.
 - **BGP4** – The metric is the Multi-exit Discriminator (MED) associated with the route. The MED applies to routes that have multiple paths through the same AS. The best route is the route with the lowest MED.

Configuring a default network route

You can configure up to four default network routes.

To configure a default network route, enter commands such as the following.

```
Brocade(config)# ip default-network 209.157.22.0
Brocade(config)# write memory
```

Syntax: `ip default-network <ip-addr>`

The `<ip-addr>` parameter specifies the network address.

To verify that the route is in the route table, enter the following command at any level of the CLI.

```
Brocade# show ip route
Total number of IP routes: 2
Start index: 1  B:BGP D:Connected  R:RIP  S:Static  O:OSPF  *:Candidate default
      Destination      NetMask      Gateway      Port    Cost    Type
1      209.157.20.0      255.255.255.0  0.0.0.0      lb1      1      D
2      209.157.22.0      255.255.255.0  0.0.0.0      4/11     1      *D
```

This example shows two routes. Both of the routes are directly attached, as indicated in the Type column. However, one of the routes is shown as type “*D”, with an asterisk (*). The asterisk indicates that this route is a candidate default network route.

Configuring IP load sharing

The IP route table can contain more than one path to a given destination. When this occurs, the Layer 3 Switch selects the path with the lowest cost as the path for forwarding traffic to the destination. If the IP route table contains more than one path to a destination and the paths each have the lowest cost, then the Layer 3 Switch uses **IP load sharing** to select a path to the destination.¹

IP load sharing uses a hashing algorithm based on the source IP address, destination IP address, and protocol field in the IP header, TCP, and UDP information.

NOTE

IP load sharing is based on next-hop routing, and not on source routing.

NOTE

The term “path” refers to the next-hop router to a destination, not to the entire route to a destination. Thus, when the software compares multiple equal-cost paths, the software is comparing paths that use different next-hop routers, with equal costs, to the same destination.

In many contexts, the terms “route” and “path” mean the same thing. Most of the user documentation uses the term “route” throughout. The term “path” is used in this section to refer to an individual next-hop router to a destination, while the term “route” refers collectively to the multiple paths to the destination. Load sharing applies when the IP route table contains multiple, equal-cost paths to a destination.

NOTE

Brocade devices also perform load sharing among the ports in aggregate links. Refer to [“Trunk group load sharing”](#) on page 705.

How multiple equal-cost paths enter the IP route table

IP load sharing applies to equal-cost paths in the IP route table. Routes that are eligible for load sharing can enter the table from any of the following sources:

- IP static routes
- Routes learned through RIP
- Routes learned through OSPF

1. IP load sharing is also called “Equal-Cost Multi-Path (ECMP)” load sharing or just “ECMP”

- Routes learned through BGP4

Administrative distance for each IP route

The administrative distance is a unique value associated with each type (source) of IP route. Each path has an administrative distance. The administrative distance is not used when performing IP load sharing, but the administrative distance is used when evaluating multiple equal-cost paths to the same destination from different sources, such as RIP, OSPF and so on.

The value of the administrative distance is determined by the source of the route. The Layer 3 Switch is configured with a unique administrative distance value for each IP route source.

When the software receives multiple paths to the same destination and the paths are from different sources, the software compares the administrative distances of the paths and selects the path with the lowest distance. The software then places the path with the lowest administrative distance in the IP route table. For example, if the Layer 3 Switch has a path learned from OSPF and a path learned from RIP for a given destination, only the path with the lower administrative distance enters the IP route table.

Here are the default administrative distances on the Brocade Layer 3 Switch:

- Directly connected – 0 (this value is not configurable)
- Static IP route – 1 (applies to all static routes, including default routes and default network routes)
- Exterior Border Gateway Protocol (EBGP) – 20
- OSPF – 110
- RIP – 120
- Interior Gateway Protocol (IBGP) – 200
- Local BGP – 200
- Unknown – 255 (the router will not use this route)

Lower administrative distances are preferred over higher distances. For example, if the router receives routes for the same network from OSPF and from RIP, the router will prefer the OSPF route by default.

NOTE

You can change the administrative distances individually. Refer to the configuration chapter for the route source for information.

Since the software selects only the path with the lowest administrative distance, and the administrative distance is determined by the path source, IP load sharing does not apply to paths from different route sources. IP load sharing applies only when the IP route table contains multiple paths to the same destination, from the same IP route source.

IP load sharing does not apply to paths that come from different sources.

Path cost

The cost parameter provides a common basis of comparison for selecting from among multiple paths to a given destination. Each path in the IP route table has a cost. When the IP route table contains multiple paths to a destination, the Layer 3 Switch chooses the path with the lowest cost. When the IP route table contains more than one path with the lowest cost to a destination, the Layer 3 Switch uses IP load sharing to select one of the lowest-cost paths.

The source of a path cost value depends on the source of the path:

- **IP static route** – The value you assign to the metric parameter when you configure the route. The default metric is 1. Refer to [“Configuring load balancing and redundancy using multiple static routes to the same destination”](#) on page 996.
- **RIP** – The number of next-hop routers to the destination.
- **OSPF** – The Path Cost associated with the path. The paths can come from any combination of inter-area, intra-area, and external Link State Advertisements (LSAs).
- **BGP4** – The path Multi-Exit Discriminator (MED) value.

NOTE

If the path is redistributed between two or more of the above sources before entering the IP route table, the cost can increase during the redistribution due to settings in redistribution filters.

Static route, OSPF, and BGP4 load sharing

IP load sharing and load sharing for static routes, OSPF routes, and BGP4 routes are individually configured. Multiple equal-cost paths for a destination can enter the IP route table only if the source of the paths is configured to support multiple equal-cost paths. For example, if BGP4 allows only one path with a given cost for a given destination, the BGP4 route table cannot contain equal-cost paths to the destination. Consequently, the IP route table will not receive multiple equal-cost paths from BGP4.

[Table 169](#) lists the default and configurable maximum numbers of paths for each IP route source that can provide equal-cost paths to the IP route table. The table also lists where to find configuration information for the route source load sharing parameters.

The load sharing state for all the route sources is based on the state of IP load sharing. Since IP load sharing is enabled by default on all Brocade Layer 3 Switches, load sharing for static IP routes, RIP routes, OSPF routes, and BGP4 routes also is enabled by default.

TABLE 169 Default load sharing parameters for route sources

Route source	Default maximum number of paths	Maximum number of paths		See...
		FSX	FCX	
Static IP route	4 ¹	6 ¹	8 ¹	page 1004
RIP	4 ¹	6 ¹	8 ¹	page 1004
OSPF	4	6	8	page 1004
BGP4	1	4	4	page 1352

1. This value depends on the value for IP load sharing, and is not separately configurable.

How IP load sharing works

When the Layer 3 Switch receives traffic for a destination and the IP route table contains multiple, equal-cost paths to that destination, the device checks the IP forwarding cache for a forwarding entry for the destination. The IP forwarding cache provides a fast path for forwarding IP traffic, including load-balanced traffic. The cache contains entries that associate a destination host or network with a path (next-hop router).

- If the IP forwarding sharing cache contains a forwarding entry for the destination, the device uses the entry to forward the traffic.

- If the IP load forwarding cache does not contain a forwarding entry for the destination, the software selects a path from among the available equal-cost paths to the destination, then creates a forwarding entry in the cache based on the calculation. Subsequent traffic for the same destination uses the forwarding entry.

Response to path state changes

If one of the load-balanced paths to a cached destination becomes unavailable, or the IP route table receives a new equal-cost path to a cached destination, the software removes the unavailable path from the IP route table. Then the software selects a new path. Disabling or re-enabling load sharing

To disable IP load sharing, enter the following commands.

```
Brocade(config)# no ip load-sharing
```

Syntax: [no] ip load-sharing

Changing the maximum number of ECMP (load sharing) paths

You can change the maximum number of paths the Layer 3 Switch supports to a value from 2 through 8. Table 170 shows the maximum number of paths supported per device.

TABLE 170 Maximum number of ECMP load sharing paths per device

FESX FSX 800 FSX 1600	FWS	FCX
6	2	8

For optimal results, set the maximum number of paths to a value at least as high as the maximum number of equal-cost paths your network typically contains. For example, if the Layer 3 Switch you are configuring for IP load sharing has six next-hop routers, set the maximum paths value to six.

NOTE

If the setting for the maximum number of paths is lower than the actual number of equal-cost paths, the software does not use all the paths for load sharing for RIP routes. Run the **clear ip route** command to fix this issue.

To change the number of IP load sharing paths, enter a command such as the following.

```
Brocade(config)# ip load-sharing 6
```

Syntax: [no] ip load-sharing [<num>]

The <num> parameter specifies the number of paths and can be from 2 through 8, depending on the device you are configuring.

ICMP Router Discovery Protocol configuration

The ICMP Router Discovery Protocol (IRDP) is used by Brocade Layer 3 Switches to advertise the IP addresses of its router interfaces to directly attached hosts. IRDP is disabled by default. You can enable the feature on a global basis or on an individual port basis:

- If you enable the feature globally, all ports use the default values for the IRDP parameters.

- If you leave the feature disabled globally but enable it on individual ports, you also can configure the IRDP parameters on an individual port basis.

NOTE

You can configure IRDP parameters only on an individual port basis. To do so, IRDP must be disabled globally and enabled only on individual ports. You cannot configure IRDP parameters if the feature is globally enabled.

When IRDP is enabled, the Layer 3 Switch periodically sends Router Advertisement messages out the IP interfaces on which the feature is enabled. The messages advertise the Layer 3 Switch IP addresses to directly attached hosts who listen for the messages. In addition, hosts can be configured to query the Layer 3 Switch for the information by sending Router Solicitation messages.

Some types of hosts use the Router Solicitation messages to discover their default gateway. When IRDP is enabled on the Brocade Layer 3 Switch, the Layer 3 Switch responds to the Router Solicitation messages. Some clients interpret this response to mean that the Layer 3 Switch is the default gateway. If another router is actually the default gateway for these clients, leave IRDP disabled on the Brocade Layer 3 Switch.

IRDP parameters

IRDP uses the following parameters. If you enable IRDP on individual ports instead of enabling the feature globally, you can configure these parameters on an individual port basis:

- **Packet type** – The Layer 3 Switch can send Router Advertisement messages as IP broadcasts or as IP multicasts addressed to IP multicast group 224.0.0.1. The packet type is IP broadcast.
- **Maximum message interval and minimum message interval** – When IRDP is enabled, the Layer 3 Switch sends the Router Advertisement messages every 450 – 600 seconds by default. The time within this interval that the Layer 3 Switch selects is random for each message and is not affected by traffic loads or other network factors. The random interval minimizes the probability that a host will receive Router Advertisement messages from other routers at the same time. The interval on each IRDP-enabled Layer 3 Switch interface is independent of the interval on other IRDP-enabled interfaces. The default maximum message interval is 600 seconds. The default minimum message interval is 450 seconds.
- **Hold time** – Each Router Advertisement message contains a hold time value. This value specifies the maximum amount of time the host should consider an advertisement to be valid until a newer advertisement arrives. When a new advertisement arrives, the hold time is reset. The hold time is always longer than the maximum advertisement interval. Therefore, if the hold time for an advertisement expires, the host can reasonably conclude that the router interface that sent the advertisement is no longer available. The default hold time is three times the maximum message interval.
- **Preference** – If a host receives multiple Router Advertisement messages from different routers, the host selects the router that sent the message with the highest preference as the default gateway. The preference can be a number from 0-4294967296 to 0-4294967295. The default is 0.

Enabling IRDP globally

To globally enable IRDP, enter the following command.

```
Brocade(config)# ip irdp
```

This command enables IRDP on the IP interfaces on all ports. Each port uses the default values for the IRDP parameters. The parameters are not configurable when IRDP is globally enabled.

Enabling IRDP on an individual port

To enable IRDP on an individual interface and change IRDP parameters, enter commands such as the following.

```
Brocade(config)# interface ethernet 1/3
Brocade(config-if-1/3)# ip irdp maxadvertinterval 400
```

This example shows how to enable IRDP on a specific port and change the maximum advertisement interval for Router Advertisement messages to 400 seconds.

NOTE

To enable IRDP on individual ports, you must leave the feature globally disabled.

Syntax: [no] ip irdp [broadcast | multicast] [holdtime <seconds>] [maxadvertinterval <seconds>] [minadvertinterval <seconds>] [preference <number>]

The **broadcast** | **multicast** parameter specifies the packet type the Layer 3 Switch uses to send Router Advertisement:

- **broadcast** – The Layer 3 Switch sends Router Advertisement as IP broadcasts. This is the default.
- **multicast** – The Layer 3 Switch sends Router Advertisement as multicast packets addressed to IP multicast group 224.0.0.1.

The **holdtime** <seconds> parameter specifies how long a host that receives a Router Advertisement from the Layer 3 Switch should consider the advertisement to be valid. When a host receives a new Router Advertisement message from the Layer 3 Switch, the host resets the hold time for the Layer 3 Switch to the hold time specified in the new advertisement. If the hold time of an advertisement expires, the host discards the advertisement, concluding that the router interface that sent the advertisement is no longer available. The value must be greater than the value of the **maxadvertinterval** parameter and cannot be greater than 9000. The default is three times the value of the **maxadvertinterval** parameter.

The **maxadvertinterval** parameter specifies the maximum amount of time the Layer 3 Switch waits between sending Router Advertisements. You can specify a value from 1 to the current value of the **holdtime** parameter. The default is 600 seconds.

The **minadvertinterval** parameter specifies the minimum amount of time the Layer 3 Switch can wait between sending Router Advertisements. The default is three-fourths (0.75) the value of the **maxadvertinterval** parameter. If you change the **maxadvertinterval** parameter, the software automatically adjusts the **minadvertinterval** parameter to be three-fourths the new value of the **maxadvertinterval** parameter. If you want to override the automatically configured value, you can specify an interval from 1 to the current value of the **maxadvertinterval** parameter.

The **preference** <number> parameter specifies the IRDP preference level of this Layer 3 Switch. If a host receives Router Advertisements from multiple routers, the host selects the router interface that sent the message with the highest interval as the host default gateway. The valid range is 0-4294967296 to 0-4294967295. The default is 0.

Reverse Address Resolution Protocol configuration

The Reverse Address Resolution Protocol (RARP) provides a simple mechanism for directly-attached IP hosts to boot over the network. RARP allows an IP host that does not have a means of storing its IP address across power cycles or software reloads to query a directly-attached router for an IP address.

RARP is enabled by default. However, you must create a RARP entry for each host that will use the Layer 3 Switch for booting. A RARP entry consists of the following information:

- The entry number – the entry sequence number in the RARP table.
- The MAC address of the boot client.
- The IP address you want the Layer 3 Switch to give to the client.

When a client sends a RARP broadcast requesting an IP address, the Layer 3 Switch responds to the request by looking in the RARP table for an entry that contains the client MAC address:

- If the RARP table contains an entry for the client, the Layer 3 Switch sends a unicast response to the client that contains the IP address associated with the client MAC address in the RARP table.
- If the RARP table does not contain an entry for the client, the Layer 3 Switch silently discards the RARP request and does not reply to the client.

How RARP Differs from BootP and DHCP

RARP and BootP/DHCP are different methods for providing IP addresses to IP hosts when they boot. These methods differ in the following ways:

- Location of configured host addresses:
 - RARP requires static configuration of the host IP addresses on the Layer 3 Switch. The Layer 3 Switch replies directly to a host request by sending an IP address you have configured in the RARP table.
 - The Layer 3 Switch forwards BootP and DHCP requests to a third-party BootP/DHCP server that contains the IP addresses and other host configuration information.
- Connection of host to boot source (Layer 3 Switch or BootP/DHCP server):
 - RARP requires the IP host to be directly attached to the Layer 3 Switch.
 - An IP host and the BootP/DHCP server can be on different networks and on different routers, so long as the routers are configured to forward (“help”) the host boot request to the boot server.
 - You can centrally configure other host parameters on the BootP/DHCP server, in addition to the IP address, and supply those parameters to the host along with its IP address.

To configure the Layer 3 Switch to forward BootP/DHCP requests when boot clients and the boot servers are on different subnets on different Layer 3 Switch interfaces, refer to [“BootP and DHCP relay parameter configuration”](#) on page 1011.

Disabling RARP

RARP is enabled by default. To disable RARP, enter the following command at the global CONFIG level.

```
Brocade(config)# no ip rarp
```

Syntax: [no] ip rarp

To re-enable RARP, enter the following command.

```
Brocade(config)# ip rarp
```

Creating static RARP entries

You must configure the RARP entries for the RARP table. The Layer 3 Switch can send an IP address in reply to a client RARP request only if create a RARP entry for that client.

To assign a static IP RARP entry for static routes on a Brocade router, enter a command such as the following.

```
Brocade(config)# rarp 1 1245.7654.2348 192.53.4.2
```

This command creates a RARP entry for a client with MAC address 1245.7654.2348. When the Layer 3 Switch receives a RARP request from this client, the Layer 3 Switch replies to the request by sending IP address 192.53.4.2 to the client.

Syntax: rarp <number> <mac-addr>.<ip-addr>

The <number> parameter identifies the RARP entry number. You can specify an unused number from 1 to the maximum number of RARP entries supported on the device. To determine the maximum number of entries supported on the device, refer to the section [“Displaying and modifying system parameter default settings”](#) on page 578.

The <mac-addr> parameter specifies the MAC address of the RARP client.

The <ip-addr> parameter specifies the IP address the Layer 3 Switch will give the client in response to the client RARP request.

Changing the maximum number of static RARP entries supported

The number of RARP entries the Layer 3 Switch supports depends on how much memory the Layer 3 Switch has. To determine how many RARP entries your Layer 3 Switch can have, display the system default information using the procedure in the section [“Displaying system parameter default values”](#) on page 578.

If your Layer 3 Switch allows you to increase the maximum number of RARP entries, you can use a procedure in the same section to do so.

NOTE

You must save the configuration to the startup-config file and reload the software after changing the RARP cache size to place the change into effect.

Configuring UDP broadcast and IP helper parameters

Some applications rely on client requests sent as limited IP broadcasts addressed to the UDP application port. If a server for the application receives such a broadcast, the server can reply to the client. Routers do not forward subnet directed broadcasts, so the client and server must be on the same network for the broadcast to reach the server. If the client and server are on different networks (on opposite sides of a router), the client request cannot reach the server.

You can configure the Layer 3 Switch to forward clients' requests to UDP application servers. To do so:

- Enable forwarding support for the UDP application port, if forwarding support is not already enabled.
- Configure a helper address on the interface connected to the clients. Specify the helper address to be the IP address of the application server or the subnet directed broadcast address for the IP subnet the server is in. A helper address is associated with a specific interface and applies only to client requests received on that interface. The Layer 3 Switch forwards client requests for any of the application ports the Layer 3 Switch is enabled to forward to the helper address.

Forwarding support for the following application ports is enabled by default:

- bootps (port 67)
- dns (port 53)
- tftp (port 69)
- time (port 37)
- netbios-ns (port 137)
- netbios-dgm (port 138)
- tacacs (port 65)

NOTE

The application names are the names for these applications that the Layer 3 Switch software recognizes, and might not match the names for these applications on some third-party devices. The numbers listed in parentheses are the UDP port numbers for the applications. The numbers come from RFC 1340.

NOTE

Forwarding support for BootP/DHCP is enabled by default. If you are configuring the Layer 3 Switch to forward BootP/DHCP requests, refer to [“BootP and DHCP relay parameter configuration”](#) on page 1011.

You can enable forwarding for other applications by specifying the application port number.

You also can disable forwarding for an application.

NOTE

If you disable forwarding for a UDP application, forwarding of client requests received as broadcasts to helper addresses is disabled. Disabling forwarding of an application does not disable other support for the application. For example, if you disable forwarding of Telnet requests to helper addresses, other Telnet support on the Layer 3 Switch is not also disabled.

Enabling forwarding for a UDP application

If you want the Layer 3 Switch to forward client requests for UDP applications that the Layer 3 Switch does not forward by default, you can enable forwarding support for the port. To enable forwarding support for a UDP application, use the following method. You also can disable forwarding for an application using this method.

NOTE

You also must configure a helper address on the interface that is connected to the clients for the application. The Layer 3 Switch cannot forward the requests unless you configure the helper address. Refer to [“Configuring an IP helper address”](#) on page 1012.

To enable the forwarding of NTP broadcasts, enter the following command.

```
Brocade(config)# ip forward-protocol udp ntp
```

Syntax: [no] ip forward-protocol udp <udp-port-name> | <udp-port-num>

The <udp-port-name> parameter can have one of the following values. For reference, the corresponding port numbers from RFC 1340 are shown in parentheses. If you specify an application name, enter the name only, not the parentheses or the port number shown here:

- bootpc (port 68)
- bootps (port 67)
- discard (port 9)
- dns (port 53)
- dnsix (port 90)
- echo (port 7)
- mobile-ip (port 434)
- netbios-dgm (port 138)
- netbios-ns (port 137)
- ntp (port 123)
- tacacs (port 65)
- talk (port 517)
- time (port 37)
- tftp (port 69)

In addition, you can specify any UDP application by using the application UDP port number.

The <udp-port-num> parameter specifies the UDP application port number. If the application you want to enable is not listed above, enter the application port number. You also can list the port number for any of the applications listed above.

To disable forwarding for an application, enter a command such as the following.

```
Brocade(config)# no ip forward-protocol udp ntp
```

This command disables forwarding of SNMP requests to the helper addresses configured on Layer 3 Switch interfaces.

Configuring an IP helper address

To forward a client broadcast request for a UDP application when the client and server are on different networks, you must configure a helper address on the interface connected to the client. Specify the server IP address or the subnet directed broadcast address of the IP subnet the server is in as the helper address.

You can configure up to 16 helper addresses on each interface. You can configure a helper address on an Ethernet port or a virtual interface.

To configure a helper address on interface 2 on chassis module 1, enter the following commands.

```
Brocade(config)# interface ethernet 1/2
Brocade(config-if-1/2)# ip helper-address 1 207.95.7.6
```

The commands in this example change the CLI to the configuration level for port 1/2, then add a helper address for server 207.95.7.6 to the port. If the port receives a client request for any of the applications that the Layer 3 Switch is enabled to forward, the Layer 3 Switch forwards the client request to the server.

Syntax: `ip helper-address <num> <ip-addr>`

The `<num>` parameter specifies the helper address number and can be from 1 through 16.

The `<ip-addr>` command specifies the server IP address or the subnet directed broadcast address of the IP subnet the server is in.

BootP and DHCP relay parameter configuration

A host on an IP network can use BootP or DHCP to obtain its IP address from a BootP/DHCP server. To obtain the address, the client sends a BootP or DHCP request. The request is a subnet directed broadcast and is addressed to UDP port 67. A limited IP broadcast is addressed to IP address 255.255.255.255 and is not forwarded by the Brocade Layer 3 Switch or other IP routers.

When the BootP or DHCP client and server are on the same network, the server receives the broadcast request and replies to the client. However, when the client and server are on different networks, the server does not receive the client request, because the Layer 3 Switch does not forward the request.

You can configure the Layer 3 Switch to forward BootP/DHCP requests. To do so, configure a helper address on the interface that receives the client requests, and specify the BootP/DHCP server IP address as the address you are helping the BootP/DHCP requests to reach. Instead of the server IP address, you can specify the subnet directed broadcast address of the IP subnet the server is in.

BootP and DHCP relay parameters

The following parameters control the Layer 3 Switch forwarding of BootP and DHCP requests:

- **Helper address** – The BootP/DHCP server IP address. You must configure the helper address on the interface that receives the BootP/DHCP requests from the client. The Layer 3 Switch cannot forward a request to the server unless you configure a helper address for the server.

- **Gateway address** – The Layer 3 Switch places the IP address of the interface that received the BootP/DHCP request in the request packet Gateway Address field (sometimes called the Router ID field). When the server responds to the request, the server sends the response as a unicast packet to the IP address in the Gateway Address field. (If the client and server are directly attached, the Gateway ID field is empty and the server replies to the client using a unicast or broadcast packet, depending on the server.)

By default, the Layer 3 Switch uses the lowest-numbered IP address on the interface that receives the request as the Gateway address. You can override the default by specifying the IP address you want the Layer 3 Switch to use.

- **Hop count** – Each router that forwards a BootP/DHCP packet increments the hop count by 1. Routers also discard a forwarded BootP/DHCP request instead of forwarding the request if the hop count is greater than the maximum number of BootP/DHCP hops allowed by the router. By default, a Brocade Layer 3 Switch forwards a BootP/DHCP request if its hop count is four or less, but discards the request if the hop count is greater than four. You can change the maximum number of hops the Layer 3 Switch will allow to a value from 1 through 15.

NOTE

The BootP/DHCP hop count is not the TTL parameter.

Configuring an IP helper address

The procedure for configuring a helper address for BootP/DHCP requests is the same as the procedure for configuring a helper address for other types of UDP broadcasts. Refer to [“Configuring an IP helper address”](#) on page 1011.

Configuring the BOOTP and DHCP reply source address

NOTE

This feature is supported on FastIron X Series and Brocade FCX Series devices. This feature is **not** supported on FastIron WS devices.

You can configure the Brocade device so that a BOOTP/DHCP reply to a client contains the server IP address as the source address instead of the router IP address. To do so, enter the following command at the Global CONFIG level of the CLI.

```
Brocade(config)# ip helper-use-responder-ip
```

Syntax: [no] ip helper-use-responder-ip

Changing the IP address used for stamping BootP and DHCP requests

When the Layer 3 Switch forwards a BootP/DHCP request, the Layer 3 Switch “stamps” the Gateway Address field. The default value the Layer 3 Switch uses to stamp the packet is the lowest-numbered IP address configured on the interface that received the request. If you want the Layer 3 Switch to use a different IP address to stamp requests received on the interface, use either of the following methods to specify the address.

The BootP/DHCP stamp address is an interface parameter. Change the parameter on the interface that is connected to the BootP/DHCP client.

To change the IP address used for stamping BootP/DHCP requests received on interface 1/1, enter commands such as the following.

```
Brocade(config)# interface ethernet 1/1
Brocade(config-if-1/1)# ip bootp-gateway 109.157.22.26
```

These commands change the CLI to the configuration level for port 1/1, then change the BootP/DHCP stamp address for requests received on port 1/1 to 192.157.22.26. The Layer 3 Switch will place this IP address in the Gateway Address field of BootP/DHCP requests that the Layer 3 Switch receives on port 1/1 and forwards to the BootP/DHCP server.

Syntax: `ip bootp-gateway <ip-addr>`

Changing the maximum number of hops to a BootP relay server

Each BootP or DHCP request includes a field Hop Count field. The Hop Count field indicates how many routers the request has passed through. When the Layer 3 Switch receives a BootP/DHCP request, the Layer 3 Switch looks at the value in the Hop Count field:

- If the hop count value is equal to or less than the maximum hop count the Layer 3 Switch allows, the Layer 3 Switch increments the hop count by one and forwards the request.
- If the hop count is greater than the maximum hop count the Layer 3 Switch allows, the Layer 3 Switch discards the request.

To change the maximum number of hops the Layer 3 Switch allows for forwarded BootP/DHCP requests, use either of the following methods.

NOTE

The BootP and DHCP hop count is not the TTL parameter.

To modify the maximum number of BootP/DHCP hops, enter the following command.

```
Brocade(config)#bootp-relay-max-hops 10
```

This command allows the Layer 3 Switch to forward BootP/DHCP requests that have passed through ten previous hops before reaching the Layer 3 Switch. Requests that have traversed 11 hops before reaching the switch are dropped. Since the hop count value initializes at zero, the hop count value of an ingressing DHCP Request packet is the number of Layer 3 routers that the packet has already traversed.

Syntax: `bootp-relay-max-hops <1 through 15>`

DHCP Server

All FastIron devices can be configured to function as DHCP Servers.

NOTE

The DHCP server is platform independent and has no differences in behavior or configuration across all FastIron platforms (FESX, FSX,FWS, FCX, and ICX).

Dynamic Host Configuration Protocol (DHCP) is a computer networking protocol used by devices (DHCP clients) to obtain leased (or permanent) IP addresses. DHCP is an extension of the Bootstrap Protocol (BOOTP). The differences between DHCP and BOOTP are the address allocation and renewal process.

DHCP introduces the concept of a lease on an IP address. Refer to [“How DHCP Client-Based Auto-Configuration and Flash image update works”](#) on page 1030. The DHCP server can allocate an IP address for a specified amount of time, or can extend a lease for an indefinite amount of time. DHCP provides greater control of address distribution within a subnet. This feature is crucial if the subnet has more devices than available IP address. In contrast to BOOTP, which has two types of messages that can be used for leased negotiation, DHCP provides 7 types of messages. Refer to [“Supported Options for DHCP Servers”](#) on page 1033.

DHCP allocates temporary or permanent network IP addresses to clients. When a client requests the use of an address for a time interval, the DHCP server guarantees not to reallocate that address within the requested time and tries to return the same network address each time the client makes a request. The period of time for which a network address is allocated to a client is called a lease. The client may extend the lease through subsequent requests. When the client is done with the address, they can release the address back to the server. By asking for an indefinite lease, clients may receive a permanent assignment.

In some environments, it may be necessary to reassign network addresses due to exhaustion of the available address pool. In this case, the allocation mechanism reuses addresses with expired leases.

Configuration Notes for configuring DHCP servers

- DHCP server is supported in the Layer 2, base Layer 3, edge Layer 3, and full Layer 3 software images.
- In the event of a controlled or forced switchover, a DHCP client will request from the DHCP server the same IP address and lease assignment that it had before the switchover. After the switchover, the DHCP Server feature will be automatically re-initialized on the new active controller or management module.
- For DHCP client hitless support in an IronStack, the **stack mac** command must be used to configure the IronStack MAC address, so that the MAC address does not change in the event of a switchover or failover. If **stack mac** is not configured, the MAC address/IP address pair assigned to a DHCP client will not match after a switchover or failover. Furthermore, in the Layer 3 router image, if the **stack mac** configuration is changed or removed and the management port has a dynamic IP address, when a DHCP client tries to renew its lease from the DHCP server, the DHCP server will assign a different IP address.
- If any address from the configured DHCP pool is used, for example by the DHCP server, TFTP server, etc., you must exclude the address from the network pool. For configuration instructions, refer to [“Specifying addresses to exclude from the address pool”](#) on page 1023.

DHCP Option 82 support

The DHCP relay agent information option (DHCP option 82) enables a DHCP relay agent to include information about itself when forwarding client-originated DHCP packets to a DHCP server. The DHCP server uses this information to implement IP address or other parameter-assignment policies.

In a metropolitan Ethernet-access environment, the DHCP server can centrally manage IP address assignments for a large number of subscribers. If DHCP option 82 is disabled, a DHCP policy can only be applied per subnet, rather than per physical port. When DHCP option 82 is enabled, a subscriber is identified by the physical port through which it connects to the network.

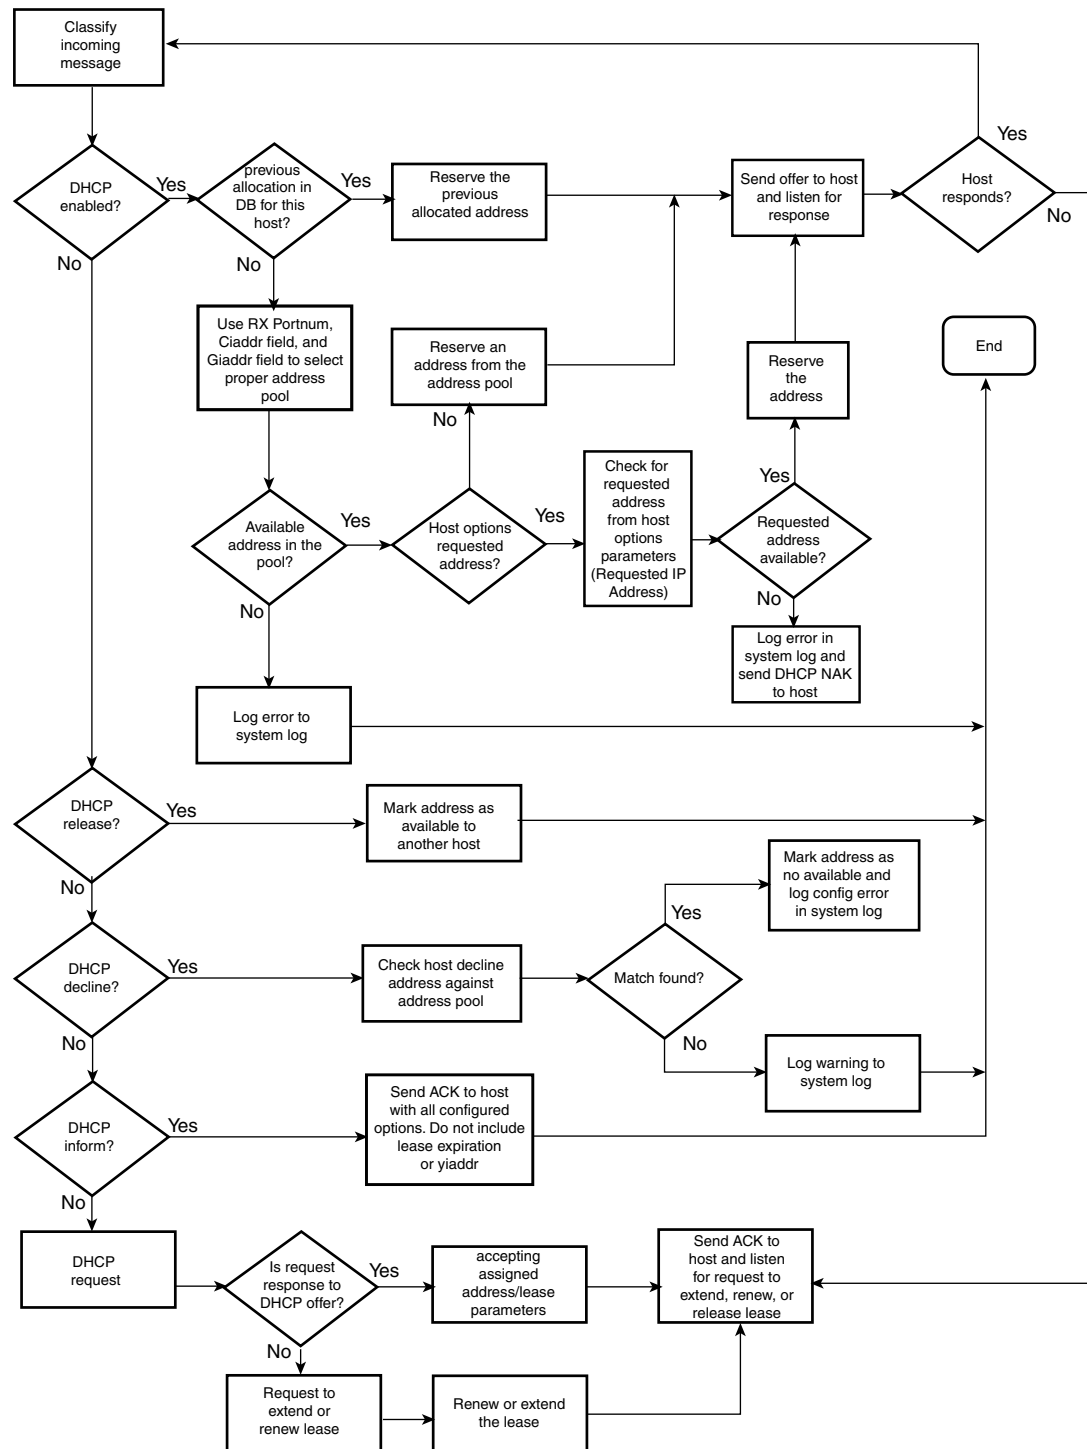

DHCP Server options

A FastIron configured as a DHCP server can support up to 1000 DHCP clients, offering them the following options:

- **NetBIOS over TCP/IP Name Server** - Specifies a list of RFC1001/1002 NBNS name servers listed in order of preference.
- **Domain Name Server** - Specifies a list of Domain Name System (RFC 1035) name servers available to the client. Servers are listed in order of preference.
- **Domain Name** - Specifies the domain name the client should use when resolving hostnames using the Domain Name system.
- **Router Option** - specifies a list of IP addresses for routers on the client subnet. Routers are listed in order of preference.
- **Subnet Mask** - Specifies the client subnet mask (per RFC950).
- **Vendor Specific Information** - Allows clients and servers to exchange vendor-specific information.
- **Boot File** - Specifies a boot image to be used by the client
- **Next Bootstrap Server** - Configures the IP address of the next server to be used for startup by the client.
- **TFTP Server** - Configures the address or name of the TFTP server available to the client.

A DHCP server assigns and manages IPv4 addresses from multiple address pools, using dynamic address allocation. The DHCP server also contains the relay agent to forward DHCP broadcast messages to network segments that do not support these types of messages.

FIGURE 116 DHCP Server configuration flow chart

Configuring DHCP Server on a device

Perform the following steps to configure the DHCP Server feature on your FastIron device:

1. Enable DHCP Server by entering a command similar to the following.

```
Brocade(config)# ip dhcp-server enable
```

2. Create a DHCP Server address pool by entering a command similar to the following.

```
Brocade(config)# ip dhcp-server pool cabo
```

3. Configure the DHCP Server address pool by entering commands similar to the following.

```
Brocade(config-dhcp-cabo)# network 172.16.1.0/24
Brocade(config-dhcp-cabo)# domain-name brocade.com
Brocade(config-dhcp-cabo)# dns-server 172.16.1.2 172.16.1.3
Brocade(config-dhcp-cabo)# netbios-name-server 172.16.1.2
Brocade(config-dhcp-cabo)# lease 0 0 5
```

4. To disable DHCP, enter a command similar to the following.

```
Brocade(config)# no ip dhcp-server enable
```

The following sections describe the default DHCP settings, CLI commands and the options you can configure for the DHCP Server feature.

Default DHCP server settings

Table 171 shows the default DHCP server settings.

TABLE 171 DHCP server default settings

Parameter	Default Value
DHCP server	Disabled
Lease database expiration time	86400 seconds
The duration of the lease for an assigned IP address	43200 seconds (one day)
Maximum lease database expiration time	86400 seconds
DHCP server with option 82	Disabled
DHCP server unknown circuit-ID for Option 82	Permit range lookup
IP distribution mechanism	Linear

DHCP server CLI commands**TABLE 172** DHCP server optional parameters commands

Command	Description
<code>dbexpire</code>	Specifies how long, in seconds, the DHCP server should wait before aborting a database transfer
<code>option domain-name</code>	Specifies the domain name for the DHCP clients.
<code>option domain-nameservers</code>	Specifies the Domain Name System (DNS) IP servers that are available to the DHCP clients.
<code>option merit-dump</code>	Specifies the path name of a file into which the client's core image should be placed in the event that the client crashes (the DHCP application issues an exception in case of errors such as division by zero).
<code>option root-path</code>	Specifies the name of the path that contains the client's root filesystem in NFS notation.
<code>option router</code>	Adds the default router and gateway for the DHCP clients.
<code>option subnet-mask</code>	Defines the subnet mask for the network.
<code>option broadcastaddress</code>	Defines a broadcast address for the network.
<code>option wins-server</code>	Defines the NetBIOS Windows Internet Naming Service (WINS) name servers that are available to Microsoft DHCP clients.
<code>option log-servers</code>	Defines a list of log servers available to the client.
<code>option bootstrapserver</code>	Specifies the IP address of the bootstrap server (the command fills the "siaddr" field in the DHCP packet).

This section describes the CLI commands that are available in the DHCP Server feature.

TABLE 173 DHCP Server CLI commands

Command	Description
ip dhcp-server arp-ping-timeout <#>	Specifies the time (in seconds) the server will wait for a response to an arp-ping packet before deleting the client from the binding database. The minimum setting is 5 seconds and the maximum time is 30 seconds. NOTE: Do not alter the default value unless it is necessary. Increasing the value of this timer may increase the time to get console access after a reboot.
clear ip dhcp-server binding	Deletes a specific, or all leases from the binding database. Refer to “Removing DHCP leases” on page 1020.
ip dhcp-server enable	Enables the DHCP server feature. Refer to “Enabling DHCP Server” on page 1020.
no ip dhcp-server mgmt	Disables DHCP server on the management port. Refer to “Disabling DHCP Server on the management port” on page 1020.
ip dhcp-server pool <name>	Switches to pool configuration mode (config-dhcp-name# prompt) and creates an address pool. Refer to “Creating an address pool” on page 1021.
ip dhcp-server relay-agent-echo enable	Enables relay agent echo (Option 82). Refer to “Enabling relay agent echo (Option 82)” on page 1021.
ip dhcp-server <server-id>	Specifies the IP address of the selected DHCP server. Refer to “Configuring the IP address of the DHCP server” on page 1021.
show ip dhcp-server binding [<address>]	Displays a specific lease entry, or all lease entries. Refer to “Displaying active lease entries” on page 1024.
show ip dhcp-server address-pool <name>	Displays a specific address pool or all address pools. Refer to “Displaying address-pool information” on page 1025.
show ip dhcp-server flash	Displays the lease binding database that is stored in flash memory. Refer to “Displaying lease-binding information in flash memory” on page 1026.
show ip dhcp-server summary	Displays a summary of active leases, deployed address pools, undeployed address pools, and server uptime. “Displaying summary DHCP server information” on page 1027.
bootfile <name>	Specifies a boot image to be used by the client. Refer to “Configuring the boot image” on page 1022.
deploy	Deploys an address pool configuration to the server. Refer to “Deploying an address pool configuration to the server” on page 1022.
dhcp-default-router <addresses>	Specifies the IP address of the default router or routers for a client. Refer to “Specifying default routers available to the client” on page 1022.
dns-server <addresses>	Specifies the IP addresses of a DNS server or servers available to the client. Refer to “Specifying DNS servers available to the client” on page 1022.
domain-name <domain>	Configures the domain name for the client. Refer to “Configuring the domain name for the client” on page 1022.
lease <days><hours><minutes>	Specifies the lease duration for an address pool. The default is a one-day lease. Refer to “Configuring the lease duration for the address pool” on page 1022.
excluded-address [<address> <address-low> <address-high>]	Specifies an address or range of addresses to be excluded from the address pool. Refer to “Specifying addresses to exclude from the address pool” on page 1023.

TABLE 173 DHCP Server CLI commands (Continued)

Command	Description
netbios-name-server <address> [<address2> <address3>]	Specifies the IP address of a NetBIOS WINS server or servers that are available to Microsoft DHCP clients. Refer to “Configuring the NetBIOS server for DHCP clients” on page 1023.
network <subnet>/<mask>	Configures the subnet network and mask of the DHCP address pool. Refer to “Configuring the subnet and mask of a DHCP address pool” on page 1023.
next-bootstrap-server <address>	Configures the IP address of the next server to be used for startup by the client. Refer to “Configuring a next-bootstrap server” on page 1023.
tftp-server <address> name <name>	Configures the address or name of the TFTP server available to the client. Refer to “Configuring the TFTP server” on page 1024.
vendor-class [<ascii> <ip> <hex> > <value>]	Specifies the vendor type and configuration value for the DHCP client. Refer to “Configuring a vendor type and configuration value for a DHCP client” on page 1024.

Removing DHCP leases

The **clear ip dhcp-server binding** command can be used to delete a specific lease, or all lease entries from the lease binding database.

```
Brocade(config)# clear ip dhcp-server binding *
```

Syntax: **clear ip dhcp-server binding** [<address> | <*>]

- <address> - The IP address to be deleted
- <*> - Clears all IP addresses

Enabling DHCP Server

The **ip dhcp-server enable** command enables DHCP Server, which is disabled by default.

Syntax: **[no] ip dhcp-server enable**

The **no** version of this command disables DHCP Server.

Disabling DHCP Server on the management port

By default, when DHCP Server is enabled, it responds to DHCP client requests received on the management port. If desired, you can prevent the response to DHCP client requests received on the management port, by disabling DHCP Server support on the port. When disabled, DHCP client requests that are received on the management port are silently discarded.

To disable DHCP Server on the management port, enter the following command at the global configuration level of the CLI.

```
Brocade(config)# no ip dhcp-server mgmt
```

To re-enable DHCP Server on the management port after it has been disabled, enter the **ip dhcp-server mgmt** command:

```
Brocade(config)# ip dhcp-server mgmt
```

Syntax: **[no] ip dhcp-server mgmt**

Setting the wait time for ARP-ping response

At startup, the server reconciles the lease-binding database by sending an ARP-ping packet out to every client. If there is no response to the ARP-ping packet within a set amount of time (set in seconds), the server deletes the client from the lease-binding database. The minimum setting is 5 seconds and the maximum is 30 seconds.

Syntax: `ip dhcp-server arp-ping-timeout <num>`

- `<num>` - The number of seconds to wait for a response to an ARP-ping packet.

NOTE

Do not alter the default value unless it is necessary. Increasing the value of this timer may increase the time to get console access after a reboot.

Creating an address pool

The `ip dhcp-server pool` command puts you in pool configuration mode, and allows you to create an address pool.

```
Brocade(config)# ip dhcp-server pool
Brocade(config-dhcp-name)# ip dhcp-server pool monterey
Brocade(config-dhcp-monterey)#
```

These commands create an address pool named monterey.

Syntax: `ip dhcp-server pool <name>`

Configuration notes for creating an address pool

- If the DHCP server address is part of a configured DHCP address pool, you must exclude the DHCP server address from the network pool. Refer to [“Specifying addresses to exclude from the address pool”](#) on page 1023.
- While in DHCP server pool configuration mode, the system will place the DHCP server pool in *pending* mode and the DHCP server will not use the address pool to distribute information to clients. To activate the pool, use the **deploy** command. Refer to [“Deploying an address pool configuration to the server”](#) on page 1022.

Enabling relay agent echo (Option 82)

The `ip dhcp-server relay-agent-echo enable` command activates DHCP Option 82, and enables the DHCP server to echo relay agent information in all replies.

```
Brocade(config)# ip dhcp-server relay-agent-echo enable
```

Syntax: `ip dhcp-server relay-agent-echo enable`

Configuring the IP address of the DHCP server

The `ip dhcp-server` command specifies the IP address of the selected DHCP server, as shown in this example:

```
Brocade(config)# ip dhcp-server 102.1.1.144
```

Syntax: `ip dhcp-server <server-identifier>`

- *<server-identifier>* - The IP address of the DHCP server

This command assigns an IP address to the selected DHCP server.

Configuring the boot image

The **bootfile** command specifies a boot image name to be used by the DHCP client.

```
Brocade(config-dhcp-cabo)# bootfile foxhound
```

In this example, the DHCP client should use the boot image called “foxhound”.

Syntax: **bootfile** *<name>*

Deploying an address pool configuration to the server

The **deploy** command sends an address pool configuration to the DHCP server.

```
Brocade(config-dhcp-cabo)# deploy
```

Syntax: **deploy**

Specifying default routers available to the client

The **dhcp-default-router** command specifies the ip addresses of the default routers for a client.

Syntax: **dhcp-default-router** *<address>* [*<address>*, *<address>*]

Specifying DNS servers available to the client

The **dns-server** command specifies DNS servers that are available to DHCP clients.

```
Brocade(config-dhcp-cabo)# dns-server 102.2.1.143, 101.2.2.142
```

Syntax: **dns-server** *<address>* [*<address>*, *<address>*]

Configuring the domain name for the client

The **domain-name** command configures the domain name for the client.

```
Brocade(config-dhcp-cabo)# domain-name sierra
```

Syntax: **domain-name** *<domain>*

Configuring the lease duration for the address pool

The **lease** command specifies the lease duration for the address pool. The default is a one-day lease.

```
Brocade(config-dhcp-cabo)# lease 1 4 32
```

In this example, the lease duration has been set to one day, four hours, and 32 minutes. You can set a lease duration for just days, just hours, or just minutes, or any combination of the three.

Syntax: **lease** *<days>* *<hours>* *<minutes>*

Specifying addresses to exclude from the address pool

The **excluded-address** command specifies either a single address, or a range of addresses that are to be excluded from the address pool.

```
Brocade(config-dhcp-cabo)# excluded-address 101.2.3.44
```

Syntax: **excluded-address** [<address> | <address-low address-high>]>

- <address> - Specifies a single address
- <address-low address-high> - Specifies a range of addresses

Configuring the NetBIOS server for DHCP clients

The **netbios-name-server** command specifies the IP address of a NetBIOS WINS server or servers that are available to Microsoft DHCP clients.

```
Brocade(config-dhcp-cabo)# netbios-name-server 192.168.1.55
```

Syntax: **netbios-name-server** <address> [<address2>, <address3>]

Configuring the subnet and mask of a DHCP address pool

This **network** command configures the subnet network and mask of the DHCP address pool.

```
Brocade(config-dhcp-cabo)# network 101.2.3.44/24
```

Syntax: **network** <subnet>/<mask>

Configuring a next-bootstrap server

The **next-bootstrap-server** command specifies the IP address of the next server the client should use for boot up.

```
Brocade(config-dhcp-cabo)# next-bootstrap-server 101.2.5.44
```

Syntax: **next-bootstrap-server** <address>

Configuring the TFTP server

The **tftp-server** command specifies the address or name of the TFTP server to be used by the DHCP clients.

To configure a TFTP server by specifying its IP address, enter a command similar to the following.

```
Brocade(config-dhcp-cabo)# tftp-server 101.7.5.48
```

To configure a TFTP server by specifying its server name, enter a command similar to the following.

```
Brocade(config-dhcp-cabo)# tftp-server tftp.domain.com
```

Syntax: **tftp-server** <address> | **name** <server-name>

- <address> is the IP address of the TFTP server.
- **name** configures the TFTP server specified by <server-name>.

If DHCP options 66 (TFTP server name) and 150 (TFTP server IP address) are both configured, the DHCP client ignores option 150 and tries to resolve the TFTP server name (option 66) using DNS.

Configuring a vendor type and configuration value for a DHCP client

The **vendor-class** command specifies the vendor-type and configuration value for a DHCP client.

```
Brocade(config-dhcp-cabo)# vendor class ascii waikiki
```

Syntax: **vendor-class** [<ascii> | <ip> | <hex>]> <value>

Displaying DHCP Server information

The following DHCP **show** commands can be entered from any level of the CLI.

Displaying active lease entries

The **show ip dhcp-server binding** command displays a specific active lease, or all active leases, as shown in the following example:

```
Brocade# show ip dhcp-server binding
```

The following output is displayed:

```
Brocade# show ip dhcp-server binding
```

Bindings from all pools:

IP Address	Client-ID/ Hardware address	Lease expiration	Type
192.168.1.2	001b.ed5d.a440	0d:0h:29m:31s	Automatic
192.168.1.3	0012.f2e1.26c0	0d:0h:29m:38s	Automatic

Syntax: **show ip dhcp-server binding** [<address>]

- <address> - Displays entries for this address only

The following table describes this output.

TABLE 174 CLI display of **show ip dhcp-server binding** command

Field	Description
IP address	The IP addresses currently in the binding database
Client ID/Hardware address	The hardware address for the client
Lease expiration	The time when this lease will expire
Type	The type of lease

Displaying address-pool information

This **show ip dhcp-server address-pool** command displays information about a specific address pool, or for all address pools.

```
Brocade# show ip dhcp-server address-pools
```

Output similar to the following is displayed, as shown here.

```
Showing all address pool(s):
```

```
Pool Name: one
Time elapsed since last save: 0d:0h:6m:52s
Total number of active leases: 2
Address Pool State: active
IP Address Exclusions: 192.168.1.45
IP Address Exclusions: 192.168.1.99 192.168.1.103
Pool Configured Options:
bootfile: example.bin
      dhcp-default-router: 192.168.1.1
      dns-server: 192.168.1.100
      domain-name: example.com
      lease: 0 0 30
      netbios-name-server: 192.168.1.101
      network: 192.168.1.0 255.255.255.0
      next-bootstrap-server: 192.168.1.102
      tftp-server: 192.168.1.103
```

Syntax: **show ip dhcp-server address-pool[s] [<name>]**

- **address-pool[s]** - If you enter address-pools, the display will show all address pools
- **<name>** - Displays information about a specific address pool

The following table describes this output.

TABLE 175 CLI display of **show ip dhcp-server address pools** command

Field	Description
Pool name	The name of the address pool
Time elapsed since last save	The time that has elapsed since the last save.
Total number of active leases	The number of leases that are currently active.
Address pool state	The state of the address pool (active or inactive).
IP Address exclusions	IP addresses that are not included in the address pool
Pool configured options	
bootfile	The name of the bootfile
dhcp-server-router	The address of the DHCP server router
dns-server	The address of the dns server
domain-name	The name of the domain
lease	The identifier for the lease
netbios-name server	The address of the netbios name server
network	The address of the network
next-bootstrap-server	The address of the next-bootstrap server
tftp-server	The address of the TFTP server

Displaying lease-binding information in flash memory

The **show ip dhcp-server flash** command displays the lease-binding database that is stored in flash memory.

```
Brocade# show ip dhcp-server flash
```

The following information is displayed.

```
Brocade# show ip dhcp-server flash
```

Address Pool Binding:

IP Address	Client-ID/ Hardware address	Lease expiration	Type
192.168.1.2	001b.ed5d.a440	0d:0h:18m:59s	Automatic
192.168.1.3	0012.f2e1.26c0	0d:0h:19m:8s	Automatic

Syntax: **show ip dhcp-server flash**

The following table describes this output.

TABLE 176 CLI display of **show ip dhcp-server flash** command

Field	Description
IP address	The IP address of the flash memory lease-binding database
Client-ID/Hardware address	The address of the client
Lease expiration	The time when the lease will expire
Type	The type of lease

Displaying summary DHCP server information

The **show ip dhcp-server summary** command displays information about active leases, deployed address-pools, undeployed address-pools, and server uptime.

```
Brocade# show ip dhcp-server summary
```

The following information is displayed.

DHCP Server Summary:

```

                Total number of active leases:  2
        Total number of deployed address-pools:  1
Total number of undeployed address-pools:  0
                Server uptime: 0d:0h:8m:27s
```

Syntax: **show ip dhcp-server summary**

The following table describes this output.

TABLE 177 CLI display of `show ip dhcp-server summary` command

Field	Description
Total number of active leases	Indicates the number of leases that are currently active
Total number of deployed address-pools	The number of address pools currently in use.
Total number of undeployed address-pools	The number of address-pools being held in reserve.
Server uptime	The amount of time that the server has been active.

TABLE 178 DHCP Server commands

Command	Description
<code>option bootstrapfilename</code>	Sets the name of the bootstrap file. The no form of this command removes the name of the bootstrap file.
<code>default-lease-time</code>	Specifies the duration of the lease for an IP address that is assigned from a DHCP server to a DHCP client.
<code>database tftp</code>	Defines the TFTP IP address server for storing the DHCP database, the name of the stored file and the time period at which the stored database is synchronized with the database on the device.
<code>database ftp</code>	Defines the FTP IP address server for storing the DHCP database, the name of the stored file and the time period at which the stored database is synchronized with the database on the device.
<code>max-lease-time</code>	Specifies the maximal duration of the leases in seconds.
<code>option bootfile-name</code>	Specifies the pathname of the boot file.
<code>option tftp-server</code>	Specifies the IP address of a TFTP server.

DHCP Client-Based Auto-Configuration and Flash image update

NOTE

The DHCP Client-Based Auto-Configuration and Flash image update are platform independent and have no differences in behavior or configuration across all platforms (FESX, FSX, FWS, and FCX).

DHCP Client-Based Auto-Configuration allows Layer 2 and Layer 3 devices to automatically obtain leased IP addresses through a DHCP server, negotiate address lease renewal, and obtain flash image and configuration files.

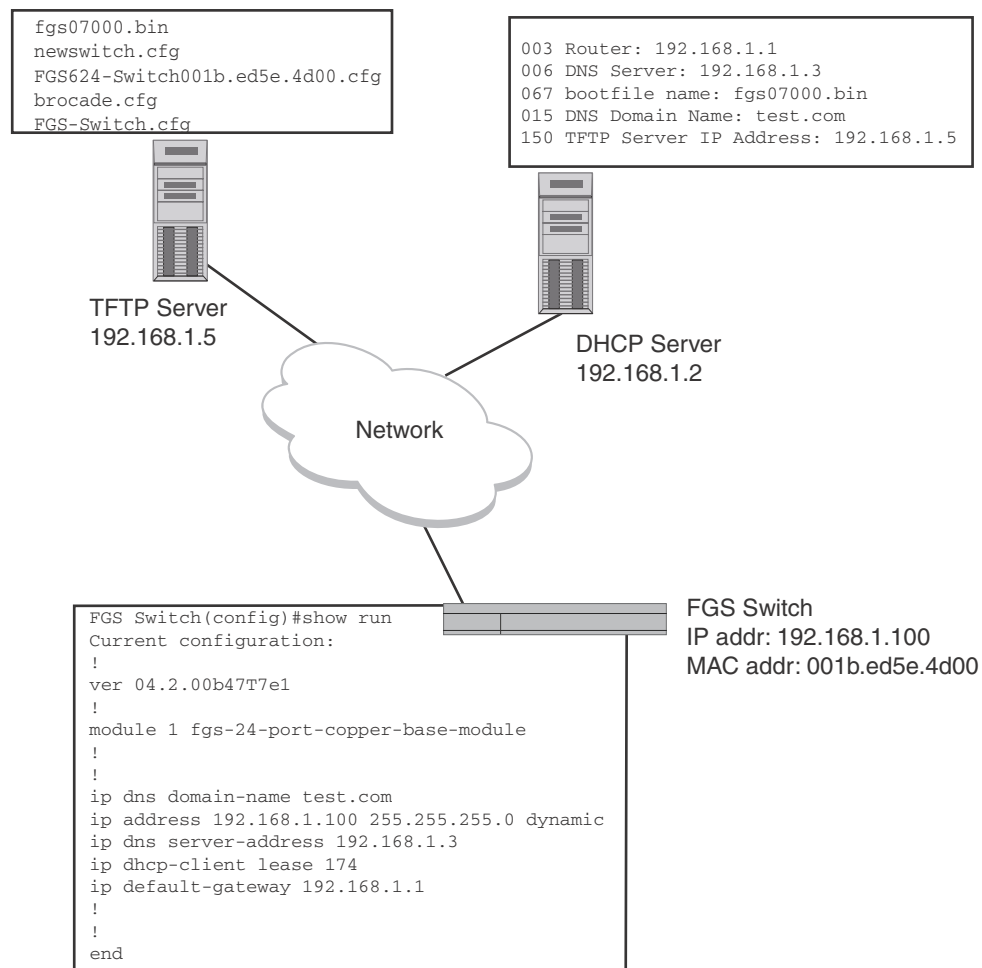

DHCP Client-Based Auto-Configuration occurs as follows.

1. The IP address validation and lease negotiation enables the DHCP client (a Brocade Layer 2 or Layer 3 device) to automatically obtain and configure an IP address, as follows:
 - One lease is granted for each Layer 2 device. If the device is configured with a static IP address, the DHCP Auto-Configuration feature is automatically disabled.
 - For a Layer 3 device, one leased address is granted (per device) to the interface that first receives a response from the DHCP server.

2. If **auto-update** is enabled, the TFTP flash image is downloaded and updated. The device compares the filename of the requested flash image with the image stored in flash. If the filenames are different, then the device will download the new image from a TFTP server, write the downloaded image to flash, then reload the device or stack.
3. In the final step, TFTP configuration download and update, the device downloads a configuration file from a TFTP server and saves it as the running configuration.

Figure 117 shows how DHCP Client-Based Auto Configuration works.

FIGURE 117 DHCP Client-Based Auto-Configuration

Configuration notes and feature limitations for DHCP client-based auto-configuration

- For Layer 3 devices, this feature is available for the default VLAN only. For Layer 2 devices, this feature is available for default VLANs and management VLANs. This feature is not supported on virtual interfaces (VEs), trunked ports, or LACP ports.
- Although the DHCP server may provide multiple addresses, only one IP address is installed at a time.

- This feature is not supported together with DHCP snooping.

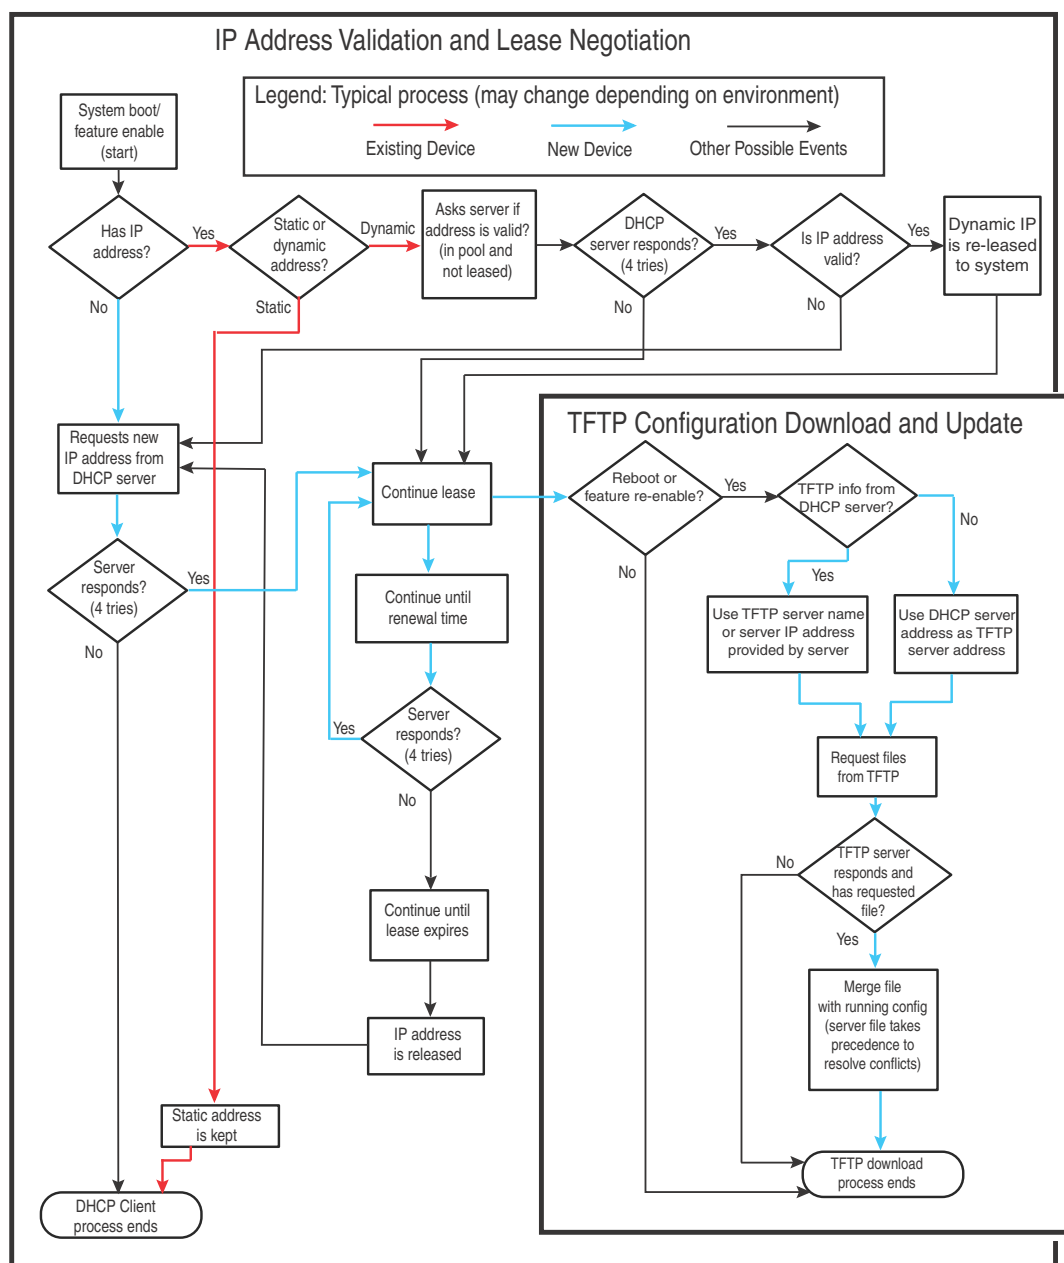

The following configuration rules apply to flash image update:

- To enable flash image update (**ip dhcp-client auto-update enable** command), also enable auto-configuration (**ip dhcp-client enable** command).
- The image filename to be updated must have the extension **.bin**.
- The DHCP option 067 bootfile name will be used for image update if it has the extension **.bin**.
- The DHCP option 067 bootfile name will be used for configuration download if it does not have the extension **.bin**.
- If the DHCP option 067 bootfile name is not configured or does not have the extension **.bin**, then the auto-update image will not occur.

How DHCP Client-Based Auto-Configuration and Flash image update works

Auto-Configuration and Auto-update are enabled by default. To disable this feature, refer to [“Disabling or re-enabling Auto-Configuration”](#) on page 1034 and [“Disabling or re-enabling Auto-Update”](#) on page 1034, respectively.

The steps of the Auto-Configuration and Auto-update process are described in [Figure 118](#), and in the description that follows the flowchart.

FIGURE 118 The DHCP Client-Based Auto-Configuration steps

Step 1. Validate the IP address and lease negotiation

1. At boot-up, the device automatically checks its configuration for an IP address.
2. If the device **does not have** a static IP address, it requests the lease of an address from the DHCP server:
 - If the server responds, it leases an IP address to the device for the specified lease period.
 - If the server does not respond (after four tries) the DHCP Client process is ended.

3. If the device **has a dynamic** address, the device asks the DHCP server to validate that address. If the server does not respond, the device will continue to use the existing address until the lease expires. If the server responds, and the IP address is outside of the DHCP address pool or has been leased to another device, it is automatically rejected, and the device receives a new IP address from the server. If the existing address is valid, the lease continues.

NOTE

The lease time interval is configured on the DHCP server, not on the client device. The **ip dhcp-client lease** command is set by the system, and is non-operational to a user.

4. If the existing address is **static**, the device keeps it and the DHCP Client process is ended.
5. For a leased IP address, when the lease interval reaches the renewal point, the device requests a renewal from the DHCP server:
 - If the device is **able** to contact the DHCP server at the renewal point in the lease, the DHCP server extends the lease. This process can continue indefinitely.
 - If the device is **unable** to reach the DHCP server after four attempts, it continues to use the existing IP address until the lease expires. When the lease expires, the dynamic IP address is removed and the device contacts the DHCP server for a new address. If the device is still unable to contact the DHCP server after four attempts, the process is ended.

The TFTP Flash image download and update step

NOTE

This process only occurs when the client device reboots, or when DHCP-client has been disabled and then re-enabled.

Once a lease is obtained from the server (described in [“Step 1. Validate the IP address and lease negotiation”](#) on page 1031), the device compares the filename of the requested flash image with the image stored in flash. In a stacking configuration, the device compares the filename with the image stored in the Active controller only.

- If the .bin filenames match, then the DHCP client skips the flash image download. If **auto-configuration** is enabled, the DHCP client proceeds with downloading the configuration files as described in [“The TFTP configuration download and update step”](#).
- If the .bin filenames are different, then the DHCP client downloads the new image from a TFTP server, then writes the downloaded image to flash. In a stacking configuration, the device copies the flash image to flash in all stack member units.

The code determines which flash (i.e., primary or secondary) to use based on how the device is booted. In a stacking configuration, the member units use the same flash as the Active controller. Once the flash is updated with the newer flash image, the device is reloaded and any member units in a stacking configuration are reloaded as well. If **auto-configuration** is enabled, the DHCP client then proceeds to download the configuration files described in [“The TFTP configuration download and update step”](#).

NOTE

In a stacking environment, the DHCP client flash image download waits 5 minutes for all member units to join and update. Then the DHCP client downloads the new image from the TFTP server using the TFTP server IP address (option 150), if it is available. If the TFTP server IP address is not available, the DHCP client requests the TFTP file from the DHCP server.

The TFTP configuration download and update step

NOTE

This process only occurs when the client device reboots, or when Auto-Configuration has been disabled and then re-enabled.

1. When the device reboots, or the Auto-Configuration feature has been disabled and then re-enabled, the device uses information from the DHCP server to contact the TFTP server to update the running-configuration file:
 - If the DHCP server provides a TFTP server name or IP address, the device uses this information to request files from the TFTP server.
 - If the DHCP server does not provide a TFTP server name or IP address, the device requests the configuration files from the DHCP server.
2. The device requests the configuration files from the TFTP server by asking for filenames in the following order:
 - **bootfile name provided by the DHCP server** (if configured)
 - **hostnameMAC-config.cfg**, for example:
FGS624p-Switch001b.ed5e.4d00-config.cfg
 - **hostnameMAC.cfg**, for example:
FGS624p-Switch001b.ed5e.4d00.cfg
 - **brocade.cfg** (applies to all devices), for example:
brocade.cfg
 - **<fcx | fgs | fls>-<switch | router>.cfg** (applies to Layer 2 or base Layer 3 devices), for example:

```
fgs-switch.cfg(FGS Layer 2)
fls-switch.cfg(FLS Layer 2)
fgs-router.cfg(FGS Base-Layer 3)
fls-router.cfg(FLS Base Layer 3)
fcx-switch.cfg(FCX Layer 2)
fcx-router.cfg(FCX Layer 3)
```

If the device is successful in contacting the TFTP server and the server has the configuration file, the files are merged. If there is a conflict, the server file takes precedence.

If the device is **unable** to contact the TFTP server or if the files are not found on the server, the TFTP part of the configuration download process ends.

Supported Options for DHCP Servers

DHCP Client supports the following options:

- 001 - subnetmask
- 003 - router ip
- 015 - domain name
- 006 - domain name server
- 012 - hostname (optional)
- 066 - TFTP server name (only used for Client-Based Auto Configuration)

- 067 - bootfile name
- 150 - TFTP server IP address (private option, datatype = IP Address)

Configuration notes for DHCP servers

- When using DHCP on a router, if you have a DHCP address for one interface, and you want to connect to the DHCP server from another interface, you must disable DHCP on the first interface, then enable DHCP on the second interface.
- When DHCP is disabled, and then re-enabled, or if the system is rebooted, the TFTP process requires approximately three minutes to run in the background before file images can be downloaded manually.
- Once a port is assigned a leased IP address, it is bound by the terms of the lease regardless of the link state of the port.

Disabling or re-enabling Auto-Configuration

For a switch, you can disable or enable this feature using the following commands.

```
Brocade(config)# ip dhcp-client enable
Brocade(config)# no ip dhcp-client enable
```

For a router, you can disable or enable this feature using the following commands.

```
Brocade(config-if-e1000-0/1/1)# ip dhcp-client enable
Brocade(config-if-e1000-0/1/1)# no ip dhcp-client enable
```

Syntax: [no] ip dhcp-client enable

Disabling or re-enabling Auto-Update

Auto-update is enabled by default. To disable it, use the following command.

```
Brocade(config)# no ip dhcp-client auto-update enabled
```

To re-enable auto-update after it has been disabled, use the following command.

```
Brocade(config)# ip dhcp-client auto-update enabled
```

Syntax: [no] ip dhcp-client auto-update enabled

Displaying DHCP configuration information

The following example shows output from the **show ip** command for Layer 2 devices.

```
Brocade(config)# show ip

Switch IP address: 10.44.16.116

Subnet mask: 255.255.255.0

Default router address: 10.44.16.1
TFTP server address: 10.44.16.41
Configuration filename: foundry.cfg
Image filename: None
```

The following example shows output from the **show ip address** command for a Layer 2 device.

```
Brocade(config)# show ip address
  IP Address      Type      Lease Time      Interface
10.44.16.116      Dynamic    174              0/1/1
```

The following example shows output from the **show ip address** command for a Layer 3 device.

```
Brocade(config)# show ip address
  IP Address      Type      Lease Time      Interface
10.44.3.233        Dynamic    672651          0/1/2
  1.0.0.1          Static     N/A              0/1/15
```

The following example shows a Layer 2 device configuration as a result of the **show run** command.

```
Brocade(config)# show run
Current configuration:
!
ver 04.2.00b47T7e1
!
module 1 fls-24-port-copper-base-module
!
!
ip address 10.44.16.116 255.255.255.0 dynamic
ip dns server-address 10.44.16.41
ip dhcp-client lease 174
ip default-gateway 10.44.16.1
!
!
end
```

NOTE

The **ip dhcp-client lease** entry in the example above applies to FastIron X Series devices only.

The following example shows a Layer 3 device configuration as a result of the **show run** command.

```
Brocade(config)# show run
Current configuration:
!
ver 04.2.00b47T7e1
!
module 1 fgs-24-port-management-module
module 2 fgs-cx4-2-port-10g-module
module 3 fgs-xfp-1-port-10g-module
!
vlan 1 name DEFAULT-VLAN by port
!
ip dns domain-name test.com
ip dns server-address 10.44.3.111
interface ethernet 0/1/2
    ip address 10.44.3.233 255.255.255.0 dynamic
    ip dhcp-client lease 691109
!
interface ethernet 0/1/15
    ip address 1.0.0.1 255.0.0.0
    ip helper-address 1 10.44.3.111
!
end
```

NOTE

The **ip dhcp-client lease** entry in the example above applies to FastIron X Series devices only.

DHCP Log messages

The following DHCP notification messages are sent to the log file.

```
2d01h48m21s:I: DHCPC: existing ip address found, no further action needed by DHCPC
2d01h48m21s:I: DHCPC: Starting DHCP Client service
2d01h48m21s:I: DHCPC: Stopped DHCP Client service
2d01h48m21s:I: DHCPC: FGS624P Switch running-configuration changed
2d01h48m21s:I: DHCPC: sending TFTP request for bootfile name fgs-switch.cfg
2d01h48m21s:I: DHCPC: TFTP unable to download running-configuration
2d01h48m21s:I: DHCPC: Found static IP Address 1.1.1.1 subnet mask 255.255.255.0 on
port 0/1/5
2d01h48m21s:I: DHCPC: Client service found no DHCP server(s) on 3 possible subnet
2d01h48m21s:I: DHCPC: changing 0/1/3 protocol from stopped to running
```

Configuring IP parameters – Layer 2 Switches

The following sections describe how to configure IP parameters on a Brocade Layer 2 Switch.

NOTE

This section describes how to configure IP parameters for Layer 2 Switches. For IP configuration information for Layer 3 Switches, refer to [“Configuring IP parameters – Layer 3 Switches”](#) on page 964.

Configuring the management IP address and specifying the default gateway

To manage a Layer 2 Switch using Telnet or Secure Shell (SSH) CLI connections or the Web Management Interface, you must configure an IP address for the Layer 2 Switch. Optionally, you also can specify the default gateway.

Brocade devices support both classical IP network masks (Class A, B, and C subnet masks, and so on) and Classless Interdomain Routing (CIDR) network prefix masks:

- To enter a classical network mask, enter the mask in IP address format. For example, enter “209.157.22.99 255.255.255.0” for an IP address with a Class-C subnet mask.
- To enter a prefix network mask, enter a forward slash (/) and the number of bits in the mask immediately after the IP address. For example, enter “209.157.22.99/24” for an IP address that has a network mask with 24 significant bits (ones).

By default, the CLI displays network masks in classical IP address format (example: 255.255.255.0). You can change the display to prefix format. Refer to [“Changing the network mask display to prefix format”](#) on page 1065.

Assigning an IP address to a Brocade Layer 2 switch

To assign an IP address to a Brocade Layer 2 Switch, enter a command such as the following at the global CONFIG level.

```
Brocade(config)# ip address 192.45.6.110 255.255.255.0
```

Syntax: `ip address <ip-addr> <ip-mask>`

or

Syntax: `ip address <ip-addr>/<mask-bits>`

You also can enter the IP address and mask in CIDR format, as follows.

```
Brocade(config)# ip address 192.45.6.1/24
```

To specify the Layer 2 Switch default gateway, enter a command such as the following.

```
Brocade(config)# ip default-gateway 192.45.6.1
```

Syntax: `ip default-gateway <ip-addr>`

NOTE

When configuring an IP address on a Layer 2 switch that has multiple VLANs, make sure the configuration includes a designated management VLAN that identifies the VLAN to which the global IP address belongs. Refer to [“Designated VLAN for Telnet management sessions to a Layer 2 Switch”](#) on page 120.

Configuring Domain Name Server (DNS) resolver

The Domain Name Server (DNS) resolver feature lets you use a host name to perform Telnet, ping, and traceroute commands. You can also define a DNS domain on a Brocade Layer 2 Switch or Layer 3 Switch and thereby recognize all hosts within that domain. After you define a domain name, the Brocade Layer 2 Switch or Layer 3 Switch automatically appends the appropriate domain to the host and forwards it to the domain name server.

For example, if the domain “newyork.com” is defined on a Brocade Layer 2 Switch or Layer 3 Switch and you want to initiate a ping to host “NYC01” on that domain, you need to reference only the host name in the command instead of the host name and its domain name. For example, you could enter either of the following commands to initiate the ping.

```
Brocade# ping nyc01
Brocade# ping nyc01.newyork.com
```

Defining a DNS entry

You can define up to four DNS servers for each DNS entry. The first entry serves as the primary default address. If a query to the primary address fails to be resolved after three attempts, the next gateway address is queried (also up to three times). This process continues for each defined gateway address until the query is resolved. The order in which the default gateway addresses are polled is the same as the order in which you enter them.

Suppose you want to define the domain name of newyork.com on a Layer 2 Switch and then define four possible default DNS gateway addresses. To do so, enter the following commands.

```
Brocade(config)# ip dns domain-name newyork.com
Brocade(config)# ip dns server-address 209.157.22.199 205.96.7.15 208.95.7.25
201.98.7.15
```

Syntax: `ip dns server-address <ip-addr> [<ip-addr>] [<ip-addr>] [<ip-addr>]`

In this example, the first IP address in the `ip dns server-address...` command becomes the primary gateway address and all others are secondary addresses. Because IP address 201.98.7.15 is the last address listed, it is also the last address consulted to resolve a query.

Using a DNS name to initiate a trace route

Suppose you want to trace the route from a Brocade Layer 2 Switch to a remote server identified as NYC02 on domain newyork.com. Because the newyork.com domain is already defined on the Layer 2 Switch, you need to enter only the host name, NYC02, as noted in the following command.

```
Brocade# traceroute nyc02
```

Syntax: `traceroute <host-ip-addr> [maxttl <value>] [minttl <value>] [numeric] [timeout <value>] [source-ip <ip addr>]`

The only required parameter is the IP address of the host at the other end of the route.

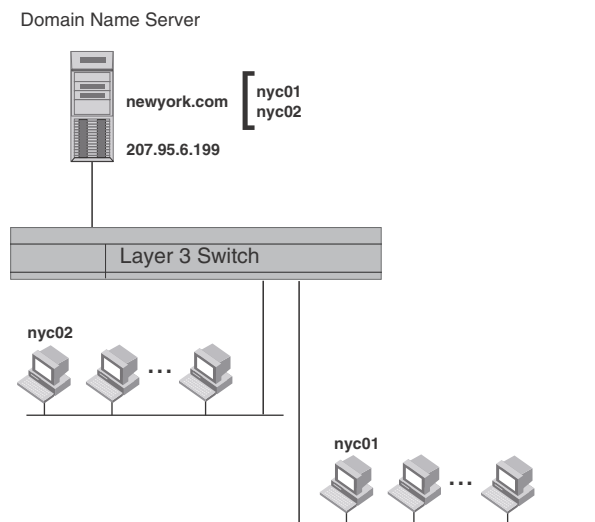

After you enter the command, a message indicating that the DNS query is in process and the current gateway address (IP address of the domain name server) being queried appear on the screen.

```
Type Control-c to abort
Sending DNS Query to 209.157.22.199
Tracing Route to IP node 209.157.22.80
To ABORT Trace Route, Please use stop-traceroute command.
Traced route to target IP node 209.157.22.80:
  IP Address      Round Trip Time1    Round Trip Time2
  207.95.6.30     93 msec            121 msec
```

NOTE

In the previous example, 209.157.22.199 is the IP address of the domain name server (default DNS gateway address), and 209.157.22.80 represents the IP address of the NYC02 host.

FIGURE 119 Querying a Host on the newyork.com Domain

Changing the TTL threshold

The time to live (TTL) threshold prevents routing loops by specifying the maximum number of router hops an IP packet originated by the Layer 2 Switch can travel through. Each device capable of forwarding IP that receives the packet decrements (decreases) the packet TTL by one. If a router receives a packet with a TTL of 1 and reduces the TTL to zero, the router drops the packet.

The default TTL is 64. You can change the TTL to a value from 1 through 255.

To modify the TTL threshold to 25, enter the following commands.

```
Brocade(config)# ip ttl 25
Brocade(config)# exit
```

Syntax: `ip ttl <1-255>`

DHCP Assist configuration

DHCP Assist allows a Brocade Layer 2 Switch to assist a router that is performing multi-netting on its interfaces as part of its DHCP relay function.

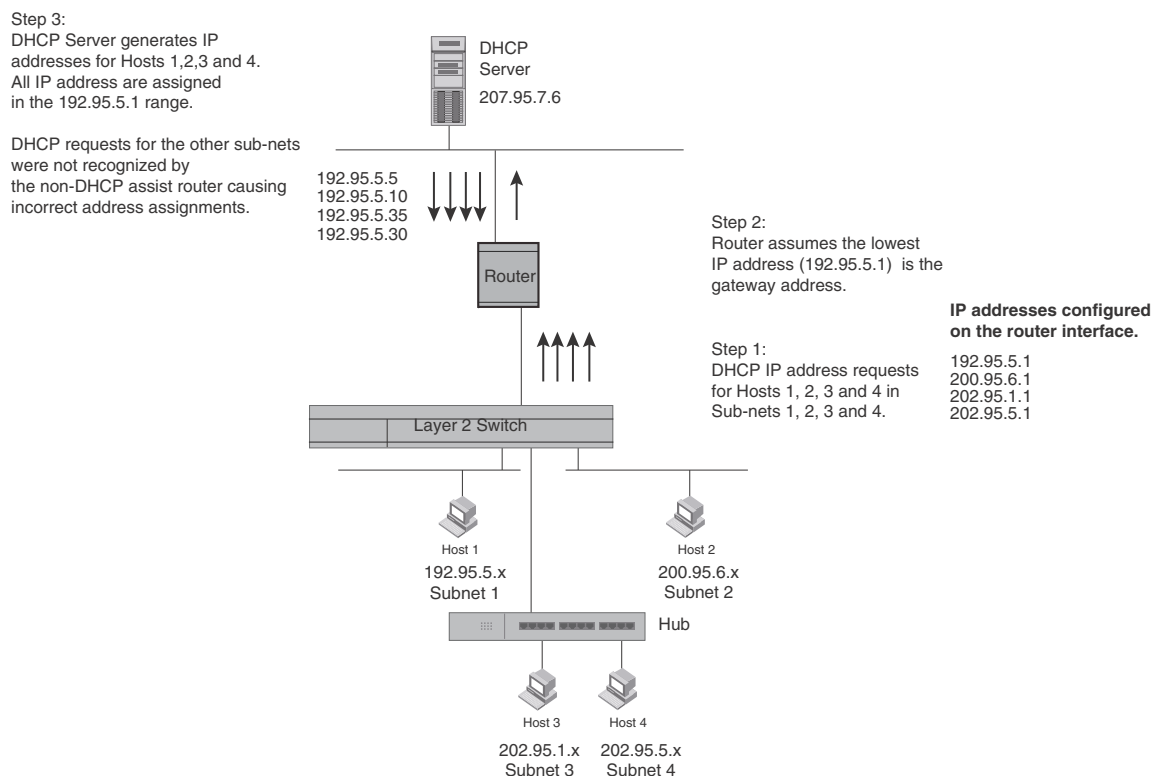

DHCP Assist ensures that a DHCP server that manages multiple IP subnets can readily recognize the requester IP subnet, even when that server is not on the client local LAN segment. The Brocade Layer 2 Switch does so by stamping each request with its IP gateway address in the DHCP discovery packet.

NOTE

Brocade Layer 3 Switches provide BootP/DHCP assistance by default on an individual port basis. Refer to [“Changing the IP address used for stamping BootP and DHCP requests”](#) on page 1012.

By allowing multiple subnet DHCP requests to be sent on the same wire, you can reduce the number of router ports required to support secondary addressing as well as reduce the number of DHCP servers required, by allowing a server to manage multiple subnet address assignments.

FIGURE 120 DHCP requests in a network without DHCP Assist on the Layer 2 Switch

In a network operating without DHCP Assist, hosts can be assigned IP addresses from the wrong subnet range because a router with multiple subnets configured on an interface cannot distinguish among DHCP discovery packets received from different subnets.

For example, in [Figure 120](#), a host from each of the four subnets supported on a Layer 2 Switch requests an IP address from the DHCP server. These requests are sent transparently to the router. Because the router is unable to determine the origin of each packet by subnet, it assumes the lowest IP address or the 'primary address' is the gateway for all ports on the Layer 2 Switch and stamps the request with that address.

When the DHCP request is received at the server, it assigns all IP addresses within that range only.

With DHCP Assist enabled on a Brocade Layer 2 Switch, correct assignments are made because the Layer 2 Switch provides the stamping service.

How DHCP Assist works

Upon initiation of a DHCP session, the client sends out a DHCP discovery packet for an address from the DHCP server as seen in [Figure 121](#). When the DHCP discovery packet is received at a Brocade Layer 2 Switch with the DHCP Assist feature enabled, the gateway address configured on the receiving interface is inserted into the packet. This address insertion is also referred to as stamping.

FIGURE 121 DHCP requests in a network with DHCP Assist operating on a FastIron Switch

When the stamped DHCP discovery packet is then received at the router, it is forwarded to the DHCP server. The DHCP server then extracts the gateway address from each request and assigns an available IP address within the corresponding IP subnet (Figure 122). The IP address is then forwarded back to the workstation that originated the request.

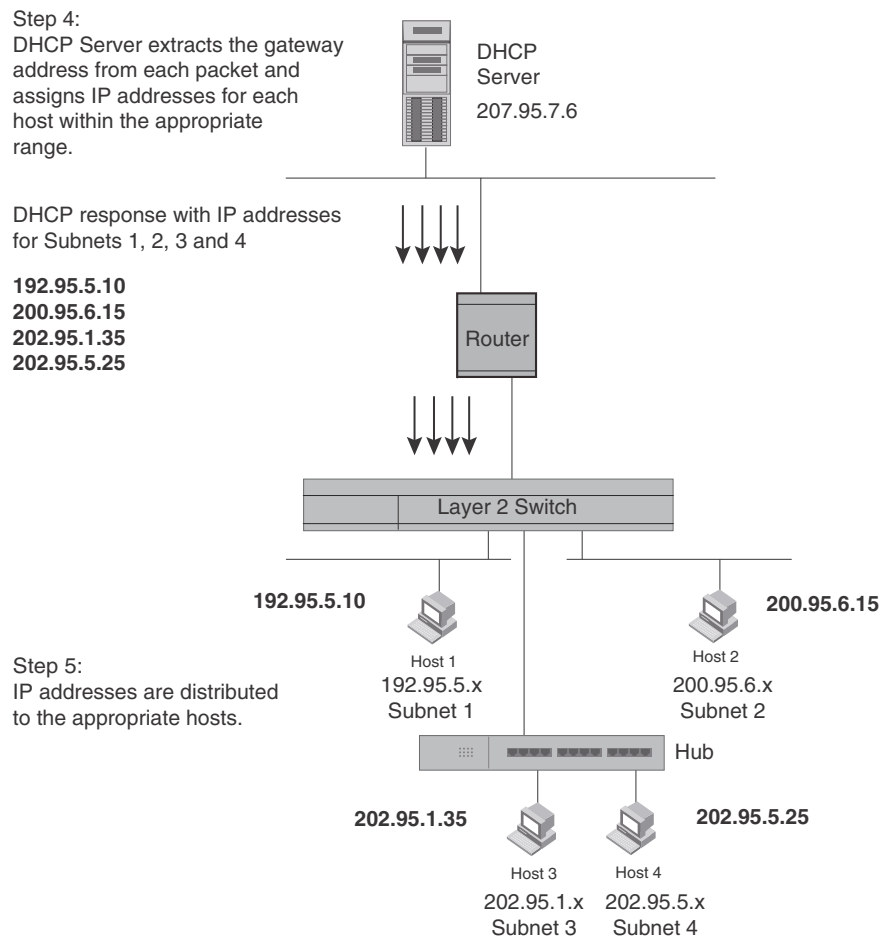

NOTE

When DHCP Assist is enabled on any port, Layer 2 broadcast packets are forwarded by the CPU. Unknown unicast and multicast packets are still forwarded in hardware, although selective packets such as IGMP, are sent to the CPU for analysis. When DHCP Assist is not enabled, Layer 2 broadcast packets are forwarded in hardware.

NOTE

The DHCP relay function of the connecting router must be turned on.

FIGURE 122 DHCP offers are forwarded back toward the requestors

NOTE

When DHCP Assist is enabled on any port, Layer 2 broadcast packets are forwarded by the CPU. Unknown unicast and multicast packets are still forwarded in hardware, although selective packets such as IGMP are sent to the CPU for analysis. When DHCP Assist is not enabled, Layer 2 broadcast packets are forwarded in hardware.

Configuring DHCP Assist

You can associate a gateway list with a port. You must configure a gateway list when DHCP Assist is enabled on a Brocade Layer 2 Switch. The gateway list contains a gateway address for each subnet that will be requesting addresses from a DHCP server. The list allows the stamping process to occur. Each gateway address defined on the Layer 2 Switch corresponds to an IP address of the Brocade router interface or other router involved.

Up to eight addresses can be defined for each gateway list in support of ports that are multi-homed. When multiple IP addresses are configured for a gateway list, the Layer 2 Switch inserts the addresses into the discovery packet in a round robin fashion.

Up to 32 gateway lists can be defined for each Layer 2 Switch.

Example

To create the configuration indicated in [Figure 121](#) and [Figure 122](#), enter commands such as the following.

```
Brocade(config)# dhcp-gateway-list 1 192.95.5.1
Brocade(config)# dhcp-gateway-list 2 200.95.6.1
Brocade(config)# dhcp-gateway-list 3 202.95.1.1 202.95.5.1
Brocade(config)# interface ethernet 2
Brocade(config-if-e1000-2)# dhcp-gateway-list 1
Brocade(config-if-e1000-2)# interface ethernet 8
Brocade(config-if-e1000-8)# dhcp-gateway-list 3
Brocade(config-if-e1000-8)# interface ethernet 14
Brocade(config-if-e1000-14)# dhcp-gateway-list 2
```

Syntax: `dhcp-gateway-list <num> <ip-addr>`

IPv4 point-to-point GRE tunnels

NOTE

This feature is supported on FCX and FastIron SX IPv6-capable devices only.

This section describes support for point-to-point Generic Routing Encapsulation (GRE) tunnels and how to configure them on a Brocade device.

GRE tunnels support includes, but is not limited to, the following:

- IPv4 over GRE tunnels. IPv6 over GRE tunnels is not supported.
- Static and dynamic unicast routing over GRE tunnels
- Multicast routing over GRE tunnels
- Hardware forwarding of IP data traffic across a GRE tunnel.
- Path MTU Discovery (PMTUD)

IPv4 GRE tunnel overview

Generic Routing Encapsulation is described in RFC 2784. Generally, GRE provides a way to encapsulate arbitrary packets (payload packet) inside of a transport protocol, and transmit them from one tunnel endpoint to another. The payload is encapsulated in a GRE packet. The resulting GRE packet is then encapsulated in a delivery protocol, then forwarded to the tunnel destination. At the tunnel destination, the packet is decapsulated to reveal the payload. The payload is then forwarded to its final destination.

Brocade IPv6-capable devices allow the tunneling of packets of the following protocols over an IPv4 network using GRE:

- OSPF V2
- BGP4
- RIP V1 and V2

NOTE

This is not supported on ICX 6450 devices.

GRE packet structure and header format

Figure 123 shows the structure of a GRE encapsulated packet.

FIGURE 123 GRE encapsulated packet structure

Figure 124 shows the GRE header format.

FIGURE 124 GRE header format

Checksum	Reserved0	Ver	Protocol Type	Checksum (optional)	Reserved (optional)
----------	-----------	-----	---------------	---------------------	---------------------

The GRE header has the following fields:

- **Checksum** – 1 bit. This field is assumed to be zero in this version. If set to 1, this means that the **Checksum (optional)** and **Reserved (optional)** fields are present and the **Checksum (optional)** field contains valid information.
- **Reserved0** – 12 bits. If bits 1 - 5 are non-zero, then a receiver must discard the packet unless RFC 1701 is implemented. Bits 6 - 12 are reserved for future use and must be set to zero in transmitted packets. This field is assumed to be zero in this version.

- **Ver** – 3 bits. The GRE protocol version. This field must be set to zero in this version.
- **Protocol Type** – 16 bits. The Ethernet protocol type of the packet, as defined in RFC 1700.
- **Checksum (optional)** – 16 bits. This field is optional. It contains the IP checksum of the GRE header and the payload packet.
- **Reserved (optional)** – 16 bits. This field is optional. It is reserved for Brocade internal use.

Path MTU Discovery (PMTUD) support

Brocade IronWare software supports the following RFCs for handling large packets over a GRE tunnel:

- RFC 1191, Path MTU Discovery
- RFC 4459, MTU and Fragmentation Issues with In-the-Network Tunneling

RFC 1191 describes a method for dynamically discovering the maximum transmission unit (MTU) of an arbitrary internet path. When a FastIron device receives an IP packet that has its Do not Fragment (DF) bit set, and the packet size is greater than the MTU value of the outbound interface, then the FastIron device returns an ICMP Destination Unreachable message to the source of the packet, with the code indicating "fragmentation needed and DF set". The ICMP Destination Unreachable message includes the MTU of the outbound interface. The source host can use this information to help determine the minimum MTU of a path to a destination.

RFC 4459 describes solutions for issues with large packets over a tunnel. The following methods, from RFC 4459, are supported in Brocade IronWare software:

- If a source attempts to send packets that are larger than the lowest MTU value along the path, PMTUD can signal to the source to send smaller packets. This method is described in Section 3.2 of RFC 4459.
- Inner packets can be fragmented before encapsulation, in such a manner that the encapsulated packet fits in the tunnel path MTU, which is discovered using PMTUD. This method is described in Section 3.4 of RFC 4459.

By default, PMTUD is enabled.

Configuration considerations for PMTUD support

Consider the following when configuring PMTUD support.

- On FCX devices, only eight different MTU values can be configured over the whole system. When the SX-FI48GPP module is installed in the FastIron SX device, the maximum number of different MTU values that can be configured is 16.
- On both FCX devices, and the SX-FI-24GPP, SX-FI48GPP, SX-FI-24HF, SX-FI-2XG, and SX-FI-8XG modules, PMTUD will not be enabled on the device if the maximum number of MTU values has already been configured in the system.
 - When a new PMTUD value is discovered, and the maximum number of different MTU values for the system is already configured, the new value will search for the nearest, but smallest MTU value relative to its own value in the system. For example, in a FCX system, the new PMTUD value is 800, and the eight different MTU values configured in the system are 600, 700, 820, 1000, 1100, 1200, 1300, and 1500. The range of MTU values that can be configured is from 576 through 1500. The new PMTUD value 800 cannot be added to the system so the nearest, but smallest MTU value is used. In this example, the MTU value of 700 is considered as the nearest MTU value already configured in the system.

- When the new PMTUD value is smaller than all of the eight MTU values configured in the system, the PMTUD feature is disabled for the tunnel, and the value is not added to the system. For example, the new PMTUD value is 620 which is smaller in value than all of the eight, different MTU path values configured in the system. The following warning message is displayed on the CLI:

```
Warning - All MTU profiles used, disabling PMTU for tunnel <tunnel_id>; new PMTU was <new pmtu discovered>
```

Tunnel loopback ports for GRE tunnels

For SX-FI624C, SX-FI624P, SX-FI624HF, and SX-FI62XG modules a physical tunnel loopback port is required for routing a decapsulated packet. When a GRE-encapsulated packet is received on a tunnel interface, and the packet needs to be decapsulated, the packet is decapsulated and sent to the tunnel loopback port. The packet is then looped back and forwarded based on the payload packets.

If a tunnel loopback port is not configured, tunnel termination is performed by the CPU. Each GRE tunnel interface can have one assigned tunnel loopback port and the same tunnel loopback port can be used for multiple tunnels.

Tunnel loopback ports for GRE tunnels are supported on:

- untagged ports
- ports that are enabled by default
- 10 Gbps and 1 Gbps copper and fiber ports

Note the following hardware limitations for these port types:

- On 10 Gbps ports, the port LEDs will be ON (green) when the ports are configured as tunnel loopback ports for GRE tunnels. Also, the LEDs will blink when data packets are forwarded.
- On 1 Gbps fiber and copper ports, port LEDs will *not* be ON when the ports are configured as tunnel loopback ports for GRE tunnels, nor will the LEDs blink when data packets are forwarded.

Tunnel loopback ports for GRE tunnels are *not* applicable on:

- tagged ports
- trunk ports
- ports that are members of a VE
- ports that are disabled
- ports that have an IP address
- flow control
- the SX-FI48GPP module

Support for IPv4 multicast routing over GRE tunnels

PIM-DM and PIM-SM Layer 3 multicast protocols and multicast data traffic are supported over GRE tunnels. When a multicast protocol is enabled on both ends of a GRE tunnel, multicast packets can be sent from one tunnel endpoint to another. To accomplish this, the packets are encapsulated using the GRE unicast tunneling mechanism and forwarded like any other IPv4 unicast packet to

the destination endpoint of the tunnel. The router that terminates the tunnel (i.e., the router where the tunnel endpoint is an ingress interface) de-encapsulates the GRE tunneled packet to retrieve the native multicast data packets. After de-encapsulation, data packets are forwarded in the direction of its receivers, and control packets may be consumed. This creates a PIM-enabled virtual or logical link between the two GRE tunnel endpoints.

Strict RPF check for multicast protocols

IronWare software enforces strict Reverse Path Forwarding (RPF) check rules on an (s,g) entry on a GRE tunnel interface. The (s,g) entry uses the GRE tunnel as an RPF interface. During unicast routing transit, GRE tunnel packets may arrive at different physical interfaces. The strict RPF check limits GRE PIM tunnel interfaces to accept the (s,g) GRE tunnel traffic.

NOTE

For the FESX624 device, and the SX-FI624C, SX-FI624P, SX-FI624HF, and the SX-FI62XG modules loopback ports are required for de-encapsulating the GRE tunneled packet. On these hardware devices, when the GRE-encapsulated multicast packet is received, the unicast GRE mechanism takes care of de-encapsulating the packet. The packet then egresses and re-ingresses the tunnel interface loopback port as the native multicast packet. The hardware RPF check is done, not on the tunnel interface directly, but on the loopback port - the hardware compares this port number with the port number configured in the Multicast table (s,g) entry. If they match, the packet is routed. Otherwise it is sent to the CPU for error processing. In unicast, it is permissible for multiple tunnel interfaces to use a single loopback port. However, in multicast, this will not allow the hardware to determine the tunnel interface that the packet was received on in order to do an RPF check. Therefore, when IPv4 Multicast Routing is enabled on a GRE tunnel, the tunnel interface must have a dedicated loopback port.

GRE support with other features

This section describes how GRE tunnels may affect other features on FESX, FSX, and FCX devices.

Support for ECMP for routes through a GRE tunnel

Equal-Cost Multi-Path (ECMP) load sharing allows for load distribution of traffic among available routes. When GRE is enabled, a mix of GRE tunnels and normal IP routes is supported. If multiple routes are using GRE tunnels to a destination, packets are automatically load-balanced between tunnels, or between tunnels and normal IP routes.

ACL, QoS, and PBR support for traffic through a GRE tunnel

NOTE

PBR and ACL filtering for packets terminating on a GRE tunnel is not supported on FCX devices. However, PBR can be used to map IP traffic into a GRE tunnel, but it cannot be used to route GRE traffic. On FCX devices, QoS support for GRE encapsulated packets is limited to copying DSCP values from the inner header onto the outer header.

For FastIron SX devices only, traffic coming from a tunnel can be filtered by an ACL both before and after the tunnel is terminated and also redirected by PBR after tunnel is terminated. An ACL classifies and sets QoS for GRE traffic. If the ACL or PBR is applied to the tunnel loopback port, it would apply to the inner IP packet header (the payload packet) after the tunnel is terminated. If the ACL is applied to the tunnel ingress port, then the delivery header (outer header) would be classified or filtered before the tunnel is terminated.

NOTE

Restrictions for using ACLs in conjunction with GRE are noted in the section [“Configuration considerations for GRE IP tunnels”](#) on page 1048. PBR can be configured on tunnel loopback ports for tunnel interfaces with no restrictions. PBR with GRE tunnel is not supported on FSX 800 and FSX 1600 with the SX-FI48GPP module.

Syslog messages related to GRE IP tunnels

Syslog messages provide management applications with information related to GRE IP tunnels. The following Syslog message is supported.

```
Tunnel: TUN-RECURSIVE-DOWN tnnl 1, Tnl disabled due to recursive routing
```

Configuration considerations for GRE IP tunnels

Before configuring GRE tunnels and tunnel options, consider the configuration notes in this section.

- GRE tunnels are not supported in a mixed hardware configuration with 48-port 10/100/1000 Mbps Ethernet POE (SX-FI48GPP) interface modules, together with IPv6-capable interface modules, or management modules with user ports.
- The mix and match mode for GRE and IPv6 tunnels are not supported.
- Hitless management is supported for GRE tunnels on any FastIron devices. Hitless management is not supported for IPv6-over-IPv4 tunnels on all FastIron devices. When IPv6 tunnels are configured, the CLI commands that execute a hitless switchover (**switch-over-active-role** command and the **hitless reload** command) are disabled.
- When GRE is enabled on a Layer 3 switch, the following features are not supported on Virtual Ethernet (VE) ports, VE member ports (ports that have IP addresses), and GRE tunnel loopback ports:
 - ACL logging
 - ACL statistics (also called ACL counting)
 - MAC address filters
 - IPv6 filters

NOTE

The above features are supported on VLANs that do not have VE ports.

- Whenever multiple IP addresses are configured on a tunnel source, the primary address of the tunnel is always used for forming the tunnel connections. Therefore, carefully check the configurations when configuring the tunnel destination.

- When a GRE tunnel is configured, you cannot configure the same routing protocol on the tunnel through which you learn the route to the tunnel destination. For example, if the FastIron learns the tunnel destination route through the OSPF protocol, you cannot configure the OSPF protocol on the same tunnel and vice-versa. When a tunnel has OSPF configured, the FastIron cannot learn the tunnel destination route through OSPF. This could cause the system to become unstable.
- The tunnel destination cannot be resolved to the tunnel itself or any other local tunnel. This is called recursive routing. This scenario would cause the tunnel interface to flap and the Syslog message TUN-RECURSIVE-DOWN to be logged. To resolve this issue, create a static route for the tunnel destination.

Configuration considerations for tunnel loopback ports

NOTE

The configuration considerations for tunnel loopback ports are supported only on FESX and FSX devices.

Consider the following when configuring tunnel loopback ports for GRE tunnels:

- For multicast traffic over a GRE tunnel, each PIM-enabled tunnel interface must have a dedicated tunnel loopback port.
- For unicast traffic, a tunnel loopback port can be oversubscribed, meaning multiple GRE tunnels (up to the maximum supported) can use the same tunnel loopback port for traffic. When oversubscribed, proper traffic classification on the tunnel loopback port is necessary in order to avoid traffic congestion. In this case, Brocade recommends that you configure the trust level at the DSCP level for QoS by adding an ACL that maps DSCP 46 to priority 5. Otherwise, loss of loopback packets may flap the tunnel interface.
- By default, when you create a tunnel loopback port for a GRE tunnel on a port that is part of the default VLAN, the port will stay in the default VLAN. Before configuring a port as a tunnel loopback port for a GRE tunnel, if the port is in the default VLAN (VLAN 1), first create a VLAN, then add the port to the VLAN. Otherwise, an error message such as the following will appear on the console when you attempt to configure a router interface for the default VLAN.

```
ERROR: Router-interface cannot be applied because of GRE loopback port 1/2
```
- Configuration of tunnel loopback ports are not applicable on the SX-FI48GPP interface module.

GRE MTU configuration considerations

The default Maximum Transmission Unit (MTU) value for packets in a GRE tunnel is 1476 bytes, or 10194 bytes for jumbo packets. The MTU of the GRE tunnel is compared with the outgoing packet before the packet is encapsulated. After encapsulation, the packet size increases by 24 bytes. Therefore, when changing the GRE tunnel MTU, set the MTU to at least 24 bytes less than the IP MTU of the outgoing interface. If the MTU is not set to at least 24 bytes less than the IP MTU, the size of the encapsulated packet will exceed the IP MTU of the outgoing interface. This will cause the packet to either be sent to the CPU for fragmentation, or the packet will be dropped if the DF (Do-Not-Fragment) bit is set in the original IP packet, and an ICMP message is sent.

Configuration tasks for GRE tunnels

Brocade recommends that you perform the configuration tasks in the order listed in Table 179.

TABLE 179 Configuration tasks for GRE tunnels

Configuration tasks	Default behavior	For more information
Required tasks		
1 Create a tunnel interface	Not assigned	“Creating a tunnel interface” on page 1051
2 Configure the source address or source interface for the tunnel interface	Not assigned	“Configuring the source address or source interface for a tunnel interface” on page 1051
3 Configure the destination address of the tunnel interface	Not assigned	“Configuring the destination address for a tunnel interface” on page 1052
4 Enable GRE encapsulation on the tunnel interface	Disabled	“Enabling GRE encapsulation on a tunnel interface” on page 1052
NOTE: Step 4 must be performed before step 6.		
5 If packets need to be terminated in hardware, configure a tunnel loopback port for the tunnel interface	Not assigned	“Tunnel loopback ports for GRE tunnels” on page 1046
NOTE: Step 5 is not applicable to FCX devices.		
6 Configure an IP address for the tunnel interface	Not assigned	“Configuring an IP address for a tunnel interface” on page 1054
7 If a route to the tunnel destination (configured in Step 3) does not already exist, create a static route and specify that the route is through the tunnel interface.	Not assigned	“Configuring a static route to a tunnel destination” on page 1054
Optional tasks		
1 Change the maximum transmission unit (MTU) value for the tunnel interface	1476 bytes or 10194 bytes (jumbo mode)	“Changing the MTU value for a tunnel interface” on page 1055
2 Change the number of GRE tunnels supported on the device	Support for 32 GRE tunnels	“Changing the maximum number of tunnels supported” on page 1055
3 Enable and configure GRE link keepalive on the tunnel interface	Disabled	“Configuring GRE link keepalive” on page 1056
4 Change the Path MTU Discovery (PMTUD) configuration on the GRE tunnel interface	Enabled	“Configuring Path MTU Discovery (PMTUD)” on page 1056
5 Enable support for IPv4 multicast routing	Disabled	“Enabling IPv4 multicast routing over a GRE tunnel” on page 1057

The following features are also supported on GRE tunnel interfaces:

- Naming the tunnel interface (CLI command **port-name**) – for configuration details, refer to [“Assigning a port name”](#) on page 40.
- Changing the Maximum Transmission Unit (MTU) (CLI command **ip mtu**) – for configuration details, refer to [“Changing the MTU on an individual port”](#) on page 975.

- Increasing the cost of routes learned on the port (CLI command **ip metric**) – for configuration details, refer to [“Changing the cost of routes learned on a port”](#) on page 1203.

After performing the configuration steps listed in Table 179, you can view the GRE configuration and observe the routes that use GRE tunnels. For details, refer to [“Displaying GRE tunneling information”](#) on page 1059.

Creating a tunnel interface

To create a tunnel interface, enter the following command at the Global CONFIG level of the CLI.

```
Brocade(config)# interface tunnel 1
Brocade(config-tnif-1)#
```

Syntax: [no] interface tunnel <tunnel-number>

The <tunnel-number> is a numerical value that identifies the tunnel being configured.

NOTE

You can also use the **port-name** command to name the tunnel. To do so, follow the configuration instructions in [“Assigning a port name”](#) on page 40.

Configuring the source address or source interface for a tunnel interface

To configure the source for a tunnel interface, specify either a source address or a source interface.

NOTE

If the destination address for a tunnel interface is not resolved, Brocade recommends that you either configure *source interface* (instead of *source address*) as the source for a tunnel interface, or enable GRE link keepalive on the tunnel interface.

The tunnel **source address** should be one of the router IP addresses configured on a physical, loopback, or VE interface, through which the other end of the tunnel is reachable.

To configure the source address for a specific tunnel interface, enter commands such as the following.

```
Brocade(config)# interface tunnel 1
Brocade(config-tnif-1)# tunnel source 36.0.8.108
```

The **source interface** should be the port number of the interface configured on a physical, loopback, or VE interface. The source interface should have at least one IP address configured on it. Otherwise, the interface will not be added to the tunnel configuration and an error message similar to the following will be displayed:

```
ERROR - Tunnel source interface 3/1 has no configured IP address.
```

To configure the source interface for a specific tunnel interface, enter commands such as the following.

```
Brocade(config)# interface tunnel 1
Brocade(config-tnif-1)# tunnel source ethernet 3/1
```

Syntax: [no] tunnel source <ip-address> | ethernet <portnum> | ve <number> | loopback <number>

The <ip-address> variable is the source IP address being configured for the specified tunnel.

The ethernet <portnum> variable is the source slot (chassis devices only) and port number of the physical interface being configured for the specified tunnel, for example 3/1.

The ve <number> variable is the VE interface number being configured for the specified tunnel.

Deleting an IP address from an interface configured as a tunnel source

To delete an IP address from an interface that is configured as a tunnel source, first remove the tunnel source from the tunnel interface then delete the IP address, as shown in the following example.

```
Brocade(config-if-e1000-1/3)# interface tunnel 8
Brocade(config-tnif-8)# no tunnel source 45.1.83.15
Brocade(config-tnif-8)# interface ethernet 1/3
Brocade(config-if-e1000-1/3)# no ip address 45.1.83.15/24
```

If you attempt to delete an IP address without first removing the tunnel source, the console will display an error message, as shown in the following example.

```
Brocade# config terminal
Brocade(config)# interface ethernet 1/3
Brocade(config-if-e1000-1/3)# no ip address 45.1.83.15/24
Error - Please remove tunnel source from tnnl 8 before removing IP address
```

NOTE

The previous error message will also display on the CLI when an interface is part of a VLAN. A VLAN cannot be deleted until the tunnel source is first removed.

Configuring the destination address for a tunnel interface

The destination address should be the address of the IP interface of the device on the other end of the tunnel.

To configure the destination address for a specific tunnel interface, enter commands such as the following.

```
Brocade(config)# interface tunnel 1
Brocade(config-tnif-1)# tunnel destination 131.108.5.2
```

Syntax: [no] tunnel destination <ip-address>

The <ip-address> variable is the destination IP address being configured for the specified tunnel.

NOTE

Ensure a route to the tunnel destination exists on the tunnel source device. Create a static route if necessary. For configuration details, refer to [“Configuring a static route to a tunnel destination”](#) on page 1054.

Enabling GRE encapsulation on a tunnel interface

To enable GRE encapsulation on a tunnel interface, enter commands such as the following.

```
Brocade(config)# interface tunnel 1
Brocade(config-tnif-1)# tunnel mode gre ip
```

Syntax: [no] tunnel mode gre ip

- **gre** specifies that the tunnel will use GRE encapsulation (IP protocol 47).
- **ip** specifies that the tunneling protocol is IPv4.

NOTE

Before configuring a new GRE tunnel, the system should have at least one slot available for adding the default tunnel MTU value to the system tables. Depending on the configuration, the default tunnel MTU range is ((1500 or 10218) - 24) . To check for slot availability, or to see if the MTU value is already configured in the IP table, use the **show ip mtu** command. For more information on the **show ip mtu** command, refer to [“Displaying multicast protocols and GRE tunneling information”](#) on page 1062.

Configuring a tunnel loopback port for a tunnel interface

NOTE

Configuring a tunnel loopback port for a tunnel interface is not applicable on FCX devices, and SX-FI-24GPP, SX-FI48GPP, SX-FI-24HF, SX-FI-2XG, and SX-FI-8XG modules.

For details and important configuration considerations regarding tunnel loopback ports for GRE tunnels, refer to [“Tunnel loopback ports for GRE tunnels”](#) on page 1046 and [“Configuration considerations for tunnel loopback ports”](#) on page 1049.

To configure a tunnel loopback port, enter commands such as the following:

```
Brocade(config)# interface tunnel 1
Brocade(config-tnif-1)# tunnel loopback 3/1
```

Syntax: [no] tunnel loopback <portnum>

The <portnum> is the slot (chassis devices) and port number of the tunnel loopback port for the specified tunnel interface, for example 3/1.

Applying an ACL or PBR to a tunnel interface on a FastIron X Series module

To apply an ACL or PBR policy to a tunnel interface on a FastIron X Series module other than the SX-FI48GPP (48-port 10/100/1000 Mbps Ethernet POE interface module), enter commands such as the following:

Applying a PBR policy to a tunnel interface

```
Brocade(config)# interface tunnel 1
Brocade(config-tnif-1)# tunnel mode gre ip
Brocade(config-tnif-1)# tunnel loopback 3
Brocade(config-tnif-1)# interface ethernet 3
Brocade(config-if-e1000-3)# ip policy route-map test-route
```

Applying an ACL policy to a tunnel interface

```
Brocade(config)# interface tunnel 1
Brocade(config-tnif-1)# tunnel mode gre ip
Brocade(config-tnif-1)# tunnel loopback 3
Brocade(config-tnif-1)# interface ethernet 3
Brocade(config-if-e1000-3)# ip access-group 10 in
```

Applying an ACL or PBR to a tunnel interface on the SX-FI48GPP interface module

To apply an ACL or PBR policy to a tunnel interface on the SX-FI48GPP interface module, enter commands such as the following:

NOTE

Configuration of tunnel loopback ports are not applicable on the SX-FI48GPP interface module.

Applying a PBR policy to a tunnel interface

```
Brocade(config)# interface tunnel 1
Brocade(config-tnif-1)# tunnel mode gre ip
Brocade(config-tnif-1)# ip policy route-map test-route
```

Applying an ACL policy to a tunnel interface

```
Brocade(config)# interface tunnel 1
Brocade(config-tnif-1)# tunnel mode gre ip
Brocade(config-tnif-1)# ip access-group 10 in
```

Configuring an IP address for a tunnel interface

An IP address sets a tunnel interface as an IP port and allows the configuration of Layer 3 protocols, such as OSPF, BGP, and Multicast (PIM-DM and PIM-SM) on the port. Note that the subnet cannot overlap other subnets configured on other routing interfaces, and both ends of the tunnel should be in the same subnet, as illustrated in the GRE tunnel configuration example in [Figure 125](#) on page 1058.

To configure an IP address for a specified tunnel interface, enter commands such as the following.

```
Brocade(config)# interface tunnel 1
Brocade(config-tnif-1)# ip address 10.10.3.1/24
```

Syntax: [no] ip address <ip-address>

The <ip-address> is the IP address being configured for the specified tunnel interface.

Configuring a static route to a tunnel destination

If a route to the tunnel destination does not already exist on the tunnel source, create a static route and set the route to go through the tunnel interface.

```
Brocade(config)# ip route 131.108.5.0/24 36.0.8.1
Brocade(config)# ip route 10.10.2.0/24 tunnel 1
```

Syntax: [no] ip route <ip-address> tunnel <tunnel-ID>

- The <ip-address> variable is the IP address of the tunnel interface.
- The <tunnel-ID> variable is a valid tunnel number or name.

Changing the MTU value for a tunnel interface

For important configuration considerations regarding this feature, refer to [“GRE MTU configuration considerations”](#) on page 1049.

You can set an MTU value for packets entering the tunnel. Packets that exceed either the default MTU value of 1476/10194 bytes (for jumbo case) or the value that you set using this command, are fragmented and encapsulated with IP/GRE headers for transit through the tunnel (if they do not have the DF bit set in the IP header). All fragments will carry the same DF bit as the incoming packet. Jumbo packets are supported, although they may be fragmented based on the configured MTU value.

NOTE

For the SX-FI8GMR6, SX-FI2XGMR6, SX-FI624HF, SX-FI624C, SX-FI624P, and the SX-FI62XG modules, all fragments will carry the same DF bit as the incoming packet. For the SX-FI-24GPP, SX-FI48GPP, SX-FI-24HF, SX-FI-2XG, and SX-FI-8XG modules and the FCX modules, the DF bit on the outer IP header after encapsulation will be set if the PMTU is enabled. If PMTU is disabled, the DF bit will be unset irrespective of the DF bit of the incoming packet.

The following command allows you to change the MTU value for packets transiting “tunnel 1”:

```
Brocade(config)# interface tunnel 1
Brocade(config-tnif-1)# ip mtu 1200
```

Syntax: `ip mtu <packet-size>`

The `<packet-size>` variable specifies the maximum size in bytes for the packets transiting the tunnel. Enter a value from 576 through 1476. The default value is 1476.

NOTE

To prevent packet loss after the 24 byte GRE header is added, make sure that any physical interface that is carrying GRE tunnel traffic has an IP MTU setting at least 24 bytes greater than the tunnel MTU setting. This configuration is only allowed on the system if the tunnel mode is set to GRE.

Changing the maximum number of tunnels supported

By default, FastIron IPv6 devices support up to 32 GRE tunnels. You can configure the device to support 16 – 64 GRE tunnels. To change the maximum number of tunnels supported, enter commands such as the following.

```
Brocade(config)# system-max gre-tunnels 16
Reload required. Please write memory and then reload or power cycle.
Brocade(config)# write memory
Brocade(config)# exit
Brocade# reload
```

NOTE

You must save the configuration (write memory) and reload the software to place the change into effect.

Syntax: `system-max gre-tunnels <number>`

The `<number>` variable specifies the number of GRE tunnels that can be supported on the device. The permissible range is 16 – 64. The **system-max gre-tunnels** command determines the interface range that is supported for an interface tunnel. For example, if the system-max value is reduced, it is possible that the configured interfaces may be rejected after a system reload.

Configuring GRE link keepalive

When GRE tunnels are used in combination with static routing or policy-based routing, and a dynamic routing protocol such as RIP, BGP, or OSPF is not deployed over the GRE tunnel, a configured tunnel does not have the ability to bring down the line protocol of either tunnel endpoint, if the far end becomes unreachable. Traffic sent on the tunnel cannot follow alternate paths because the tunnel is always UP. To avoid this scenario, enable GRE link keepalive, which will maintain or place the tunnel in an UP or DOWN state based upon the periodic sending of keepalive packets and the monitoring of responses to the packets. If the packets fail to reach the tunnel far end more frequently than the configured number of retries, the tunnel is placed in the DOWN state.

To enable GRE link keepalive, configure it on one end of the tunnel and ensure the other end of the tunnel has GRE enabled.

To configure GRE link keepalive, enter commands such as the following.

```
Brocade(config)# interface tunnel 1
Brocade(config-tnif-1)# keepalive 12 4
```

These commands configure the device to wait for 4 consecutive lost keepalive packets before bringing the tunnel down. There will be a 12 second interval between each packet. Note that when the tunnel comes up, it would immediately (within one second) send the first keepalive packet.

Syntax: `[no] keepalive <seconds> <retries>`

Use the **no** form of the command to disable the keepalive option.

The `<seconds>` variable specifies the number of seconds between each initiation of a keepalive message. The range for this interval is 2 – 32767 seconds. The default value is 10 seconds.

The `<retries>` variable specifies the number of times that a packet is sent before the system places the tunnel in the DOWN state. Possible values are from 1 through 255. The default number of retries is 3.

Use the **show interface tunnel** and **show ip tunnel traffic** commands to view the GRE link keepalive configuration. For details, refer to [“Displaying GRE tunneling information”](#) on page 1059.

Configuring Path MTU Discovery (PMTUD)

Path MTU Discovery (PMTUD) support is described in the section [“Path MTU Discovery \(PMTUD\) support”](#) on page 1045. PMTUD is enabled by default on tunnel interfaces. This section describes how to disable and re-enable PMTUD on a tunnel interface, change the PMTUD age timer, manually clear the tunnel PMTUD, and view the PMTUD configuration.

NOTE

For the SX-FI8GMR6, SX-FI2XGMR6, SX-FI624HF, SX-FI624C, SX-FI624P, and the SX-FI62XG modules, all fragments will carry the same DF bit as the incoming packet. For the SX-FI-24GPP, SX-FI48GPP, SX-FI-24HF, SX-FI-2XG, and SX-FI-8XG modules and the FCX modules, the DF bit on the outer IP header after encapsulation will be set if the PMTU is enabled. If PMTU is disabled, the DF bit will be unset irrespective of the DF bit of the incoming packet.

Disabling and re-enabling PMTUD

PMTUD is enabled by default. To disable it, enter the following command:

```
Brocade(config-tnif-1)# tunnel path-mtu-discovery disable
```

To re-enable PMTUD after it has been disabled, enter the following command:

```
Brocade(config-tnif-1)# no tunnel path-mtu-discovery disable
```

Syntax: [no] tunnel path-mtu-discovery disable

Changing the age timer for PMTUD

By default, when PMTUD is enabled on a tunnel interface, the path MTU is reset to its original value every 10 minutes. If desired, you can change the reset time (default age timer) to a value of up to 30 minutes. To do so, enter a command such as the following on the GRE tunnel interface.

```
Brocade(config-tnif-1)# tunnel path-mtu-discovery age-timer 20
```

This command configures the device to wait for 20 minutes before resetting the path MTU to its original value.

Syntax: [no] tunnel path-mtu-discovery age-timer <minutes> | infinite

For <minutes>, enter a value from 10 to 30.

Enter **infinite** to disable the timer.

Clearing the PMTUD dynamic value

To reset a dynamically-configured MTU on a tunnel Interface back to the configured value, enter the following command.

```
Brocade(config)# clear ip tunnel pmtud 1
```

Syntax: clear ip tunnel pmtud <tunnel-ID>

The <tunnel-ID> variable is a valid tunnel number or name.

Viewing PMTUD configuration details

Use the **show interface tunnel** command to view the PMTUD configuration and to determine whether PMTUD has reduced the size of the MTU. For details about the **show interface tunnel** command, refer to [“Displaying GRE tunneling information”](#) on page 1059.

Enabling IPv4 multicast routing over a GRE tunnel

This section describes how to enable IPv4 multicast protocols, PIM Sparse (PIM-SM) and PIM Dense (PIM-DM), on a GRE tunnel. Perform the procedures in this section after completing the required tasks in [Table 179](#) on page 1050.

For an overview of multicast routing support over a GRE tunnel, refer to [“Support for IPv4 multicast routing over GRE tunnels”](#) on page 1046. To view information about multicast protocols and GRE tunnel-specific information, refer to [“Displaying multicast protocols and GRE tunneling information”](#) on page 1062.

NOTE

For the FESX624 module, and the SX-FI624C, SX-FI624P, SX-FI624HF, and the SX-FI62XG modules, each PIM-enabled tunnel interface must have a *dedicated* tunnel loopback port. This differs from GRE tunnels that support unicast traffic only. For unicast traffic, multiple GRE tunnels can use the same tunnel loopback port for traffic.

Enabling PIM-SM on a GRE tunnel

To enable PIM-SM on a GRE tunnel interface, enter commands such as the following:

```
Brocade(config)# interface tunnel 10
Brocade(config-tunif-10)# ip pim-sparse
```

Syntax: [no] ip pim-sparse

Use the **no** form of the command to disable PIM-SM on the tunnel interface.

Enabling PIM-DM on a GRE tunnel interface

To enable PIM-DM on a GRE tunnel interface, enter commands such as the following:

```
Brocade(config)# interface tunnel 10
Brocade(config-tunif-10)# ip pim
```

Syntax: [no] ip pim

Use the **no** form of the command to disable PIM-DM on the tunnel interface.

Example point-to-point GRE tunnel configuration

In the configuration example shown in Figure 125, a GRE Tunnel is configured between FastIron A and Brocade B. Traffic between networks 10.10.1.0/24 and 10.10.2.0/24 is encapsulated in a GRE packet sent through the tunnel on the 10.10.3.0 network, and unpacked and sent to the destination network. A static route is configured at each Layer 3 switch to go through the tunnel interface to the target network.

FIGURE 125 Point-to-point GRE tunnel configuration example

The following shows the configuration commands for the example shown in Figure 125.

NOTE

The configuration examples for FastIron A and FastIron B applies only to FastIron SX devices.

Configuring point-to-point GRE tunnel for FastIron A

```

Brocade (config)# interface ethernet 3/1
Brocade (config-if-e1000-3/1)# ip address 36.0.8.108/24
Brocade (config)# exit
Brocade (config)# interface tunnel 1
Brocade(config-tnif-1)# tunnel source 36.0.8.108
Brocade(config-tnif-1)# tunnel destination 131.108.5.2

```

Displaying GRE tunneling information

This section describes the **show** commands that display the GRE tunnels configuration, the link status of the GRE tunnels, and the routes that use GRE tunnels. To display information about multicast protocols and GRE tunnels, refer to [“Displaying multicast protocols and GRE tunneling information”](#) on page 1062.

To display GRE tunneling Information, use the following commands:

- **show ip interface**
- **show ip route**
- **show ip interface tunnel**
- **show ip tunnel traffic**
- **show interface tunnel**
- **show statistics tunnel**

The following shows an example output of the **show ip interface** command, which includes information about GRE tunnels.

```

Brocade# show ip interface

```

Interface	IP-Address	OK?	Method	Status	Protocol
Tunnel 1	10.10.3.1	YES	NVRAM	up	up

For field definitions, refer to [Table 183](#) on page 1069.

Syntax: show ip interface

The **show ip route** command displays routes that are pointing to a GRE tunnel as shown in the following example.

```
Brocade# show ip route
Total number of IP routes: 3, avail: 79996 (out of max 80000)
B:BGP D:Connected R:RIP S:Static O:OSPF *:Candidate default
      Destination      NetMask      Gateway      Port      Cost      Type
1      7.1.1.0          255.255.255.0  0.0.0.0      7          1          D
2      7.1.2.0          255.255.255.0  7.1.1.3      7          1          S
3      10.34.3.0         255.255.255.0  0.0.0.0      tn3         1          D
```

For field definitions, refer to [Table 187](#) on page 1076.

Syntax: show ip route

The **show ip interface tunnel** command displays the link status and IP address configuration for an IP tunnel interface as shown in the following example.

```
Brocade# show ip interface tunnel 1
Interface Tunnel 1
  port state: UP
  ip address: 21.21.21.2      subnet mask: 255.255.255.0
  encapsulation: GRE, mtu: 1476, metric: 1
  directed-broadcast-forwarding: disabled
  proxy-arp: disabled
  ip arp-age: 10 minutes
  No Helper Addresses are configured
  No inbound ip access-list is set
  No outgoing ip access-list is set
```

Syntax: show ip interface tunnel [<tunnel-ID>]

The **<tunnel-ID>** variable is a valid tunnel number or name.

The **show interface tunnel** command displays the GRE tunnel configuration.

```
Brocade# show int tunnel 3
Tunnel3 is up, line protocol is up
  Hardware is Tunnel
  Tunnel source 7.1.1.1
  Tunnel destination is 7.1.2.3
  Tunnel loopback is not configured
  Port name is customer1001
  Internet address is 10.34.3.2/24, MTU 1476 bytes, encapsulation GRE
  Keepalive is Enabled : Interval 10, No.of Retries 3
  Total Keepalive Pkts Tx: 2, Rx: 2
  Path MTU Discovery: Enabled, MTU is 1476 bytes
```

Syntax: show interface tunnel [<tunnel-ID>]

This display shows the following information.

TABLE 180 CLI display of **show interface tunnel** command

Field	Definition
Hardware is Tunnel	The interface is a tunnel interface.
Tunnel source	The source address for the tunnel.
Tunnel destination	The destination address for the tunnel.

TABLE 180 CLI display of **show interface tunnel** command (Continued)

Field	Definition
Tunnel loopback	The tunnel loopback port for the tunnel (if applicable).
Port name	The port name (if applicable).
Internet address	The internet address.
MTU	The maximum transmission unit.
encapsulation GRE	GRE encapsulation is enabled on the port.
Keepalive	Indicates whether or not GRE link keepalive is enabled.
Interval	If GRE link keepalive is enabled, this field displays the number of seconds between each initiation of a GRE link keepalive message.
No. of Retries	If GRE link keepalive is enabled, this field displays the number of times that a GRE link keepalive packet is sent before the tunnel is placed in the DOWN state.
Total Keepalive Pkts	If GRE link keepalive is enabled, this field shows the total number of GRE link keepalive packets transmitted (TX) and received (RX) on the tunnel since it was last cleared by the administrator.
Path MTU Discovery	Indicates whether or not PMTUD is enabled. If PMTUD is enabled, the MTU value is also displayed.

The **show ip tunnel traffic** command displays the link status of the tunnel and the number of keepalive packets received and sent on the tunnel.

```
Brocade# show ip tunnel traffic
IP GRE Tunnels
      Tunnel Status  Packet Received  Packet Sent  KA recv  KA sent
  1   up/up         362             0           362      362
  3   up/up         0               0           0        0
 10  down/down      0               0           0        0
```

Syntax: show ip tunnel traffic

The **show statistics tunnel** [*<tunnel-ID>*] command displays GRE tunnel statistics for a specific tunnel ID number. The following shows an example output for tunnel ID 1.

```
Brocade(config-tnif-10)#show statistics tunnel 1
IP GRE Tunnels
      Tunnel Status  Packet Received  Packet Sent  KA recv  KA sent
  1   up/up         87120          43943      43208    43855
```

Syntax: show statistics tunnel [*<tunnel-ID>*]

The *<tunnel-ID>* variable specifies the tunnel ID number.

This display shows the following information.

TABLE 181 CLI display of **show ip tunnel traffic** command

Field	Description
Tunnel Status	Indicates whether the tunnel is up or down. Possible values are: <ul style="list-style-type: none"> • Up/Up – The tunnel and line protocol are up. • Up/Down – The tunnel is up and the line protocol is down. • Down/Up – The tunnel is down and the line protocol is up. • Down/Down – The tunnel and line protocol are down.
Packet Received	The number of packets received on the tunnel since it was last cleared by the administrator.
Packet Sent	The number of packets sent on the tunnel since it was last cleared by the administrator.
KA rcv	The number of keepalive packets received on the tunnel since it was last cleared by the administrator.
KA sent	The number of keepalive packets sent on the tunnel since it was last cleared by the administrator.

Displaying multicast protocols and GRE tunneling information

The following **show** commands display information about multicast protocols and GRE tunnels:

- **show ip pim interface**
- **show ip pim nbr**
- **show ip pim mcache**
- **show ip pim flow**
- **show statistics**
- **show ip mtu**

NOTE

All other **show** commands that are supported currently for Ethernet, VE, and IP loopback interfaces, are also supported for tunnel interfaces. To display information for a tunnel interface, specify the tunnel in the format **tn <num>**. For example, **show interface tn 1**. In some cases, the Ethernet port that the tunnel is using will be displayed in the format **tn<num>:e<port>**.

The following shows an example output of the **show ip pim interface** command. The lines in bold highlight the GRE tunnel-specific information.

```
Brocade# show ip pim interface
Interface e1
PIM Dense: V2
TTL Threshold: 1, Enabled, DR: itself
Local Address: 10.10.10.10

Interface tn1
PIM Dense: V2
TTL Threshold: 1, Enabled, DR: 1.1.1.20 on tn1:e2
Local Address: 1.1.1.10
Neighbor:
    1.1.1.20
```

Syntax: **show ip pim interface**

The following shows an example output of the **show ip pim nbr** command. The line in bold shows the GRE tunnel-specific information.

```
Brocade# show ip pim nbr
Total number of neighbors: 1 on 1 ports
Port   Phy_p      Neighbor      Holdtime Age    UpTime
tnl     tnl:e2      1.1.1.20      180      60     1740
```

Syntax: show ip pim nbr

The following shows an example output of the **show ip pim mcache** command. The line in bold shows the GRE tunnel-specific information.

```
Brocade# show ip pim mcache 230.1.1.1
1      (10.10.10.1 230.1.1.1) in e1 (e1), cnt=629
      Source is directly connected
      L3 (HW) 1: tnl:e2(VL1)
      fast=1 slow=0 pru=1 graft
      age=120s up-time=8m HW=1 L2-vidx=8191 has mll
```

Syntax: show ip pim mcache <ip-address>

The following shows an example output of the **show ip pim flow** command. The text in bold highlights the GRE tunnel-specific information.

```
Brocade# show ip pim flow 230.1.1.1

Multicast flow (10.10.10.1 230.1.1.1):
  Vidx for source vlan forwarding: 8191 (Blackhole, no L2 clients)
  Hardware MC Entry hit on devices: 0 1 2 3
  MC Entry[0x0c008040]: 00014001 000022ee 0ffc0001 00000000
  --- MLL contents read from Device 0 ---
  MLL Data[0x018c0010]: 0021ff8d 00000083 00000000 00000000
  First   : Last:1, outlif:60043fff1 00000000, TNL:1(e2)

1 flow printed
```

Syntax: show ip pim flow

The following shows an example output of the **show statistics** command. The following statistics demonstrate an example where the encapsulated multicast traffic ingresses a tunnel endpoint on port e 2, egresses and re-ingresses as native multicast traffic on the loopback port e 4, and is then forwarded to the outbound interface e 1.

```
Brocade# show statistics
```

Port	In Packets	Out Packets	In Errors	Out Errors
1	0	1670	0	0
2	1668	7	0	0
3	0	0	0	0
4	1668	1668	0	0

Syntax: show statistics

The **show ip mtu** command can be used to see if there is space available for the `ip_default_mtu_24` value in the system, or if the MTU value is already configured in the IP table. The following shows an example output of the **show ip mtu** command.

```
Brocade(config-tnif-10)#show ip mtu
idx   size  usage  ref-count
0     10218    1    default
1       800    0         1
2       900    0         1
3       750    0         1
4     10194    1         1
5     10198    0         1
```

Syntax: `show ip mtu`

Clearing GRE statistics

Use the **clear ip tunnel** command to clear statistics related to GRE tunnels.

To clear GRE tunnel statistics, enter a command such as the following.

```
Brocade(config)# clear ip tunnel stat 3
```

To reset a dynamically-configured MTU on a tunnel Interface back to the configured value, enter a command such as the following.

```
Brocade(config)#clear ip tunnel pmtud 3
```

Syntax: `clear ip tunnel [pmtud < tunnel-ID> | stat < tunnel-ID>]`

Use the **pmtud** option to reset a dynamically-configured MTU on a tunnel Interface back to the configured value.

Use the **stat** option to clear tunnel statistics.

The `<tunnel-ID>` variable is a valid tunnel number or name.

Use the **clear statistics tunnel** [`<tunnel-ID>`] command to clear GRE tunnel statistics for a specific tunnel ID number. To clear GRE tunnel statistics for tunnel ID 3, enter a command such as the following.

```
Brocade(config)# clear statistics tunnel 3
```

Syntax: `clear statistics tunnel [<tunnel-ID>]`

The `<tunnel-ID>` variable specifies the tunnel ID number.

Displaying IP configuration information and statistics

The following sections describe IP display options for Layer 3 Switches and Layer 2 Switches:

- To display IP information on a Layer 3 Switch, refer to [“Displaying IP information – Layer 3 Switches”](#) on page 1065.
- To display IP information on a Layer 2 Switch, refer to [“Displaying IP information – Layer 2 Switches”](#) on page 1080.

Changing the network mask display to prefix format

By default, the CLI displays network masks in classical IP address format (example: 255.255.255.0). You can change the displays to prefix format (example: /18) on a Layer 3 Switch or Layer 2 Switch using the following CLI method.

NOTE

This option does not affect how information is displayed in the Web Management Interface.

To enable CIDR format for displaying network masks, entering the following command at the global CONFIG level of the CLI.

```
Brocade(config)# ip show-subnet-length
```

Syntax: [no] ip show-subnet-length

Displaying IP information – Layer 3 Switches

You can display the following IP configuration information statistics on Layer 3 Switches:

- Global IP parameter settings and IP access policies – refer to [“Displaying global IP configuration information”](#) on page 1066.
- CPU utilization statistics – refer to [“Displaying CPU utilization statistics”](#) on page 1067.
- IP interfaces – refer to [“Displaying IP interface information”](#) on page 1069.
- ARP entries – refer to [“Displaying ARP entries”](#) on page 1070.
- Static ARP entries – refer to [“Displaying ARP entries”](#) on page 1070.
- IP forwarding cache – refer to [“Displaying the forwarding cache”](#) on page 1073.
- IP route table – refer to [“Displaying the IP route table”](#) on page 1074.
- IP traffic statistics – refer to [“Displaying IP traffic statistics”](#) on page 1077.

The following sections describe how to display this information.

In addition to the information described below, you can display the following IP information. This information is described in other parts of this guide:

- RIP
- OSPF
- BGP4
- PIM
- DVMRP
- VRRP or VRRP-E

Displaying global IP configuration information

To display IP configuration information, enter the following command at any CLI level.

```
Brocade# show ip
```

Global Settings

```
ttl: 64, arp-age: 10, bootp-relay-max-hops: 4
router-id : 207.95.11.128
enabled : UDP-Broadcast-Forwarding IRDP Proxy-ARP RARP OSPF
disabled: BGP4 Load-Sharing RIP DVMRP FSRP VRRP
```

Static Routes

Index	IP Address	Subnet Mask	Next Hop Router	Metric	Distance
1	0.0.0.0	0.0.0.0	209.157.23.2	1	1

Policies

Index	Action	Source	Destination	Protocol	Port	Operator
1	deny	209.157.22.34	209.157.22.26	tcp	http	=
64	permit	any	any			

Syntax: show ip

NOTE

This command has additional options, which are explained in other sections in this guide, including the sections following this one.

This display shows the following information.

TABLE 182 CLI display of global IP configuration information – Layer 3 Switch

Field	Description
Global settings	
ttl	The Time-To-Live (TTL) for IP packets. The TTL specifies the maximum number of router hops a packet can travel before reaching the Brocade router. If the packet TTL value is higher than the value specified in this field, the Brocade router drops the packet. To change the maximum TTL, refer to “Changing the TTL threshold” on page 987.
arp-age	The ARP aging period. This parameter specifies how many minutes an inactive ARP entry remains in the ARP cache before the router ages out the entry. To change the ARP aging period, refer to “Changing the ARP aging period” on page 983.
bootp-relay-max-hops	The maximum number of hops away a BootP server can be located from the Brocade router and still be used by the router clients for network booting. To change this value, refer to “Changing the maximum number of hops to a BootP relay server” on page 1013.
router-id	The 32-bit number that uniquely identifies the Brocade router. By default, the router ID is the numerically lowest IP interface configured on the router. To change the router ID, refer to “Changing the router ID” on page 976.
enabled	The IP-related protocols that are enabled on the router.
disabled	The IP-related protocols that are disabled on the router.
Static routes	
Index	The row number of this entry in the IP route table.
IP Address	The IP address of the route destination.
Subnet Mask	The network mask for the IP address.

TABLE 182 CLI display of global IP configuration information – Layer 3 Switch (Continued)

Field	Description
Next Hop Router	The IP address of the router interface to which the Brocade router sends packets for the route.
Metric	The cost of the route. Usually, the metric represents the number of hops to the destination.
Distance	The administrative distance of the route. The default administrative distance for static IP routes in Brocade routers is 1. To list the default administrative distances for all types of routes or to change the administrative distance of a static route, refer to “Changing the administrative distance” on page 1204.
Policies	
Index	The policy number. This is the number you assigned the policy when you configured it.
Action	The action the router takes if a packet matches the comparison values in the policy. The action can be one of the following: <ul style="list-style-type: none"> deny – The router drops packets that match this policy. permit – The router forwards packets that match this policy.
Source	The source IP address the policy matches.
Destination	The destination IP address the policy matches.
Protocol	The IP protocol the policy matches. The protocol can be one of the following: <ul style="list-style-type: none"> ICMP IGMP IGRP OSPF TCP UDP
Port	The Layer 4 TCP or UDP port the policy checks for in packets. The port can be displayed by its number or, for port types the router recognizes, by the well-known name. For example, TCP port 80 can be displayed as HTTP. NOTE: This field applies only if the IP protocol is TCP or UDP.
Operator	The comparison operator for TCP or UDP port names or numbers. NOTE: This field applies only if the IP protocol is TCP or UDP.

Displaying CPU utilization statistics

You can display CPU utilization statistics for IP protocols using the **show process cpu** command.

The **show process cpu** command includes CPU utilization statistics for ACL, 802.1x, and L2VLAN. L2VLAN contains any packet transmitted to a VLAN by the CPU, including unknown unicast, multicast, broadcast, and CPU forwarded Layer 2 traffic.

To display CPU utilization statistics for the previous one-second, one-minute, five-minute, and fifteen-minute intervals, enter the following command at any level of the CLI.

Displaying IP configuration information and statistics

```
Brocade# show process cpu
Process Name    5Sec(%)    1Min(%)    5Min(%)    15Min(%)    Runtime(ms)
ACL             0.00       0.00       0.00       0.00        0
ARP             0.01       0.01       0.01       0.01       714
BGP             0.00       0.00       0.00       0.00        0
DOT1X          0.00       0.00       0.00       0.00        0
GVRP           0.00       0.00       0.00       0.00        0
ICMP           0.00       0.00       0.00       0.00       161
IP             0.00       0.00       0.00       0.00       229
L2VLAN         0.01       0.00       0.00       0.01       673
OSPF           0.00       0.00       0.00       0.00        0
RIP            0.00       0.00       0.00       0.00        9
STP            0.00       0.00       0.00       0.00        7
VRRP           0.00       0.00       0.00       0.00        0
```

If the software has been running less than 15 minutes (the maximum interval for utilization statistics), the command indicates how long the software has been running. Here is an example.

```
Brocade# show process cpu
The system has only been up for 6 seconds.
Process Name    5Sec(%)    1Min(%)    5Min(%)    15Min(%)    Runtime(ms)
ACL             0.00       0.00       0.00       0.00        0
ARP             0.01       0.01       0.01       0.01       714
BGP             0.00       0.00       0.00       0.00        0
DOT1X          0.00       0.00       0.00       0.00        0
GVRP           0.00       0.00       0.00       0.00        0
ICMP           0.00       0.00       0.00       0.00       161
IP             0.00       0.00       0.00       0.00       229
L2VLAN         0.01       0.00       0.00       0.01       673
OSPF           0.00       0.00       0.00       0.00        0
RIP            0.00       0.00       0.00       0.00        9
STP            0.00       0.00       0.00       0.00        7
VRRP           0.00       0.00       0.00       0.00        0
```

To display utilization statistics for a specific number of seconds, enter a command such as the following.

```
Brocade# show process cpu 2
Statistics for last 1 sec and 80 ms
Process Name    Sec(%)    Time(ms)
ACL             0         0.00
ARP             1         0.01
BGP             0         0.00
DOT1X           0         0.00
GVRP            0         0.00
ICMP            0         0.00
IP              0         0.00
L2VLAN          1         0.01
OSPF            0         0.00
RIP             0         0.00
STP             0         0.00
VRRP            0         0.00
```

When you specify how many seconds' worth of statistics you want to display, the software selects the sample that most closely matches the number of seconds you specified. In this example, statistics are requested for the previous two seconds. The closest sample available is actually for the previous 1 second plus 80 milliseconds.

Syntax: `show process cpu [<num>]`

The `<num>` parameter specifies the number of seconds and can be from 1 through 900. If you use this parameter, the command lists the usage statistics only for the specified number of seconds. If you do not use this parameter, the command lists the usage statistics for the previous one-second, one-minute, five-minute, and fifteen-minute intervals.

Displaying IP interface information

To display IP interface information, enter the following command at any CLI level.

```
Brocade# show ip interface
```

Interface	IP-Address	OK?	Method	Status	Protocol
Ethernet 1/1	207.95.6.173	YES	NVRAM	up	up
Ethernet 1/2	3.3.3.3	YES	manual	up	up
Loopback 1	1.2.3.4	YES	NVRAM	down	down

Syntax: `show ip interface [ethernet [<slotnum>/<portnum>] | [loopback <num>] | [ve <num>]`

This display shows the following information.

TABLE 183 CLI display of interface IP configuration information

Field	Description
Interface	The type and the slot and port number of the interface.
IP-Address	The IP address of the interface. NOTE: If an "s" is listed following the address, this is a secondary address. When the address was configured, the interface already had an IP address in the same subnet, so the software required the "secondary" option before the software could add the interface.
OK?	Whether the IP address has been configured on the interface.
Method	Whether the IP address has been saved in NVRAM. If you have set the IP address for the interface in the CLI or Web Management Interface, but have not saved the configuration, the entry for the interface in the Method field is "manual".
Status	The link status of the interface. If you have disabled the interface with the disable command, the entry in the Status field will be "administratively down". Otherwise, the entry in the Status field will be either "up" or "down".
Protocol	Whether the interface can provide two-way communication. If the IP address is configured, and the link status of the interface is up, the entry in the protocol field will be "up". Otherwise the entry in the protocol field will be "down".

To display detailed IP information for a specific interface, enter a command such as the following.

```
Brocade# show ip interface ethernet 1/1
Interface Ethernet 1/1
  port state: UP
  ip address: 192.168.9.51      subnet mask: 255.255.255.0
  encapsulation: ETHERNET, mtu: 1500, metric: 1
  directed-broadcast-forwarding: disabled
  proxy-arp: disabled
  ip arp-age: 10 minutes
  Ip Flow switching is disabled
  No Helper Addresses are configured.
  No inbound ip access-list is set
  No outgoing ip access-list is set
```

Displaying ARP entries

You can display the ARP cache and the static ARP table. The ARP cache contains entries for devices attached to the Layer 3 Switch. The static ARP table contains the user-configured ARP entries. An entry in the static ARP table enters the ARP cache when the entry interface comes up.

The tables require separate display commands or Web management options.

Displaying the ARP cache

To display the contents of the ARP cache, enter the following command at any CLI level.

```
Brocade# show arp

Total number of ARP entries: 5, maximum capacity: 6000

| No. | IP Address   | MAC Address    | Type    | Age | Port | Status |
|-----|--------------|----------------|---------|-----|------|--------|
| 1   | 207.95.6.102 | 0800.5afc.ea21 | Dynamic | 0   | 6    | Valid  |
| 2   | 207.95.6.18  | 00a0.24d2.04ed | Dynamic | 3   | 6    | Pend   |
| 3   | 207.95.6.54  | 00a0.24ab.cd2b | Dynamic | 0   | 6    | Pend   |
| 4   | 207.95.6.101 | 0800.207c.a7fa | Dynamic | 0   | 6    | Valid  |
| 5   | 207.95.6.211 | 00c0.2638.ac9c | Dynamic | 0   | 6    | Valid  |

```

Syntax: `show arp [ethernet [<slotnum>]/<portnum> | mac-address <xxxx.xxxx.xxxx> [<mask>] | <ip-addr> [<ip-mask>]] [<num>]`

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter lets you restrict the display to entries for a specific port.

The `mac-address <xxxx.xxxx.xxxx>` parameter lets you restrict the display to entries for a specific MAC address.

The `<mask>` parameter lets you specify a mask for the `mac-address <xxxx.xxxx.xxxx>` parameter, to display entries for multiple MAC addresses. Specify the MAC address mask as “f”s and “0”s, where “f”s are significant bits.

The `<ip-addr>` and `<ip-mask>` parameters let you restrict the display to entries for a specific IP address and network mask. Specify the IP address masks in standard decimal mask format (for example, 255.255.0.0).

NOTE

The `<ip-mask>` parameter and `<mask>` parameter perform different operations. The `<ip-mask>` parameter specifies the network mask for a specific IP address, whereas the `<mask>` parameter provides a filter for displaying multiple MAC addresses that have specific values in common.

The `<num>` parameter lets you display the table beginning with a specific entry number.

NOTE

The entry numbers in the ARP cache are not related to the entry numbers for static ARP table entries.

This display shows the following information. The number in the left column of the CLI display is the row number of the entry in the ARP cache. This number is not related to the number you assign to static MAC entries in the static ARP table.

TABLE 184 CLI display of ARP cache

Field	Description
Total number of ARP Entries	The number of entries in the ARP cache.
Maximum capacity	The total number of ARP entries supported on the device.
IP Address	The IP address of the device.
MAC Address	The MAC address of the device.
Type	<p>The ARP entry type, which can be one of the following:</p> <ul style="list-style-type: none"> • Dynamic – The Layer 3 Switch learned the entry from an incoming packet. • Static – The Layer 3 Switch loaded the entry from the static ARP table when the device for the entry was connected to the Layer 3 Switch. • DHCP – The Layer 3 Switch learned the entry from the DHCP binding address table. <p>NOTE: If the type is DHCP, the port number will not be available until the entry gets resolved through ARP.</p>
Age	<p>The number of minutes before which the ARP entry was refreshed. If this value reaches the ARP aging period, the entry is removed from the table.</p> <p>To display the ARP aging period, refer to “Displaying global IP configuration information” on page 1066. To change the ARP aging interval, refer to “Changing the ARP aging period” on page 983.</p> <p>NOTE: Static entries do not age out.</p>
Port	<p>The port on which the entry was learned.</p> <p>NOTE: If the ARP entry type is DHCP, the port number will not be available until the entry gets resolved through ARP.</p>
Status	<p>The status of the entry, which can be one of the following:</p> <ul style="list-style-type: none"> • Valid – This a valid ARP entry. • Pend – The ARP entry is not yet resolved.

Displaying the static ARP table

To display the static ARP table instead of the ARP cache, enter the following command at any CLI level.

```
Brocade# show ip static-arp
```

```
Static ARP table size: 512, configurable from 512 to 1024
  Index  IP Address      MAC Address      Port
  1      207.95.6.111     0800.093b.d210   1/1
  3      207.95.6.123     0800.093b.d211   1/1
```

This example shows two static entries. Note that because you specify an entry index number when you create the entry, it is possible for the range of index numbers to have gaps, as shown in this example.

NOTE

The entry number you assign to a static ARP entry is not related to the entry numbers in the ARP cache.

Syntax: `show ip static-arp [ethernet [<slotnum>/]<portnum> | mac-address <xxxx.xxxx.xxxx> [<mask>] | <ip-addr> [<ip-mask>]] [<num>]`

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter lets you restrict the display to entries for a specific port.

The `mac-address <xxxx.xxxx.xxxx>` parameter lets you restrict the display to entries for a specific MAC address.

The `<mask>` parameter lets you specify a mask for the `mac-address <xxxx.xxxx.xxxx>` parameter, to display entries for multiple MAC addresses. Specify the MAC address mask as “f”s and “0”s, where “f”s are significant bits.

The `<ip-addr>` and `<ip-mask>` parameters let you restrict the display to entries for a specific IP address and network mask. Specify the IP address masks in standard decimal mask format (for example, 255.255.0.0).

NOTE

The `<ip-mask>` parameter and `<mask>` parameter perform different operations. The `<ip-mask>` parameter specifies the network mask for a specific IP address, whereas the `<mask>` parameter provides a filter for displaying multiple MAC addresses that have specific values in common.

The `<num>` parameter lets you display the table beginning with a specific entry number.

TABLE 185 CLI display of static ARP table

Field	Description
Static ARP table size	The maximum number of static entries that can be configured on the device using the current memory allocation. The range of valid memory allocations for static ARP entries is listed after the current allocation. To change the memory allocation for static ARP entries, refer to “Changing the maximum number of entries the static ARP table can hold” on page 986.
Index	The number of this entry in the table. You specify the entry number when you create the entry.
IP Address	The IP address of the device.
MAC Address	The MAC address of the device.
Port	The port attached to the device the entry is for.

Displaying the forwarding cache

To display the IP forwarding cache, enter the following command at any CLI level.

```
Brocade# show ip cache
```

```
Total number of cache entries: 3
D:Dynamic P:Permanent F:Forward U:Us C:Complex Filter
W:Wait ARP I:ICMP Deny K:Drop R:Fragment S:Snap Encap
      IP Address      Next Hop      MAC      Type  Port  Vlan  Pri
1      192.168.1.11    DIRECT      0000.0000.0000  PU    n/a    0
2      192.168.1.255    DIRECT      0000.0000.0000  PU    n/a    0
3      255.255.255.255  DIRECT      0000.0000.0000  PU    n/a    0
```

Syntax: `show ip cache [<ip-addr>] | [<num>]`

The `<ip-addr>` parameter displays the cache entry for the specified IP address.

The `<num>` parameter displays the cache beginning with the row following the number you enter. For example, to begin displaying the cache at row 10, enter the following command.

show ip cache 9

The **show ip cache** command displays the following information.

TABLE 186 CLI display of IP forwarding cache – Layer 3 Switch

Field	Description
IP Address	The IP address of the destination.
Next Hop	The IP address of the next-hop router to the destination. This field contains either an IP address or the value DIRECT. DIRECT means the destination is either directly attached or the destination is an address on this Brocade device. For example, the next hop for loopback addresses and broadcast addresses is shown as DIRECT.
MAC	The MAC address of the destination. NOTE: If the entry is type U (indicating that the destination is this Brocade device), the address consists of zeroes.

TABLE 186 CLI display of IP forwarding cache – Layer 3 Switch (Continued)

Field	Description
Type	The type of host entry, which can be one or more of the following: <ul style="list-style-type: none"> • D – Dynamic • P – Permanent • F – Forward • U – Us • C – Complex Filter • W – Wait ARP • I – ICMP Deny • K – Drop • R – Fragment • S – Snap Encap
Port	The port through which this device reaches the destination. For destinations that are located on this device, the port number is shown as “n/a”.
VLAN	Indicates the VLANs the listed port is in.
Pri	The QoS priority of the port or VLAN.

Displaying the IP route table

To display the IP route table, enter the **show ip route** command at any CLI level.

```

Brocade# show ip route
Total number of IP routes: 514
Start index: 1  B:BGP D:Connected  R:RIP  S:Static  O:OSPF *:Candidate default
Destination      NetMask          Gateway          Port    Cost    Type
1.1.0.0           255.255.0.0      99.1.1.2        1/1     2       R
1.2.0.0           255.255.0.0      99.1.1.2        1/1     2       R
1.3.0.0           255.255.0.0      99.1.1.2        1/1     2       R
1.4.0.0           255.255.0.0      99.1.1.2        1/1     2       R
1.5.0.0           255.255.0.0      99.1.1.2        1/1     2       R
1.6.0.0           255.255.0.0      99.1.1.2        1/1     2       R
1.7.0.0           255.255.0.0      99.1.1.2        1/1     2       R
1.8.0.0           255.255.0.0      99.1.1.2        1/1     2       R
1.9.0.0           255.255.0.0      99.1.1.2        1/1     2       R
1.10.0.0          255.255.0.0      99.1.1.2        1/1     2       S

```

Syntax: **show ip route** [*<ip-addr>*] [*<ip-mask>*] [**longer**] [**none-bgp**] | *<num>* | **bgp** | **direct** | **ospf** | **rip** | **static**

The *<ip-addr>* parameter displays the route to the specified IP address.

The *<ip-mask>* parameter lets you specify a network mask or, if you prefer CIDR format, the number of bits in the network mask. If you use CIDR format, enter a forward slash immediately after the IP address, then enter the number of mask bits (for example: 209.157.22.0/24 for 209.157.22.0 255.255.255.0).

The **longer** parameter applies only when you specify an IP address and mask. This option displays only the routes for the specified IP address and mask. Refer to the following example.

The **none-bgp** parameter displays only the routes that did not come from BGP4.

The *<num>* option display the route table entry whose row number corresponds to the number you specify. For example, if you want to display the tenth row in the table, enter “10”.

The **bgp** option displays the BGP4 routes.

The **direct** option displays only the IP routes that are directly attached to the Layer 3 Switch.

The **ospf** option displays the OSPF routes.

The **rip** option displays the RIP routes.

The **static** option displays only the static IP routes.

The **default** routes are displayed first.

Here is an example of how to use the **direct** option. To display only the IP routes that go to devices directly attached to the Layer 3 Switch, enter the following command.

```
Brocade# show ip route direct
Start index: 1  B:BGP D:Connected  R:RIP  S:Static  O:OSPF *:Candidate default
      Destination      NetMask      Gateway      Port    Cost    Type
      209.157.22.0      255.255.255.0  0.0.0.0      4/11    1        D
```

Notice that the route displayed in this example has “D” in the Type field, indicating the route is to a directly connected device.

Here is an example of how to use the **static** option. To display only the static IP routes, enter the following command.

```
Brocade# show ip route static
Start index: 1  B:BGP D:Connected  R:RIP  S:Static  O:OSPF *:Candidate default
      Destination      NetMask      Gateway      Port    Cost    Type
      192.144.33.11     255.255.255.0  209.157.22.12  1/1     2        S
```

Notice that the route displayed in this example has “S” in the Type field, indicating the route is static.

Here is an example of how to use the **longer** option. To display only the routes for a specified IP address and mask, enter a command such as the following.

```
Brocade# show ip route 209.159.0.0/16 longer
Starting index: 1 B:BGP D:Directly-Connected R:RIP S:Static O:OSPF
Destination NetMask Gateway Port Cost Type

52 209.159.38.0 255.255.255.0 207.95.6.101 1/1 1 S
53 209.159.39.0 255.255.255.0 207.95.6.101 1/1 1 S
54 209.159.40.0 255.255.255.0 207.95.6.101 1/1 1 S
55 209.159.41.0 255.255.255.0 207.95.6.101 1/1 1 S
56 209.159.42.0 255.255.255.0 207.95.6.101 1/1 1 S
57 209.159.43.0 255.255.255.0 207.95.6.101 1/1 1 S
58 209.159.44.0 255.255.255.0 207.95.6.101 1/1 1 S
59 209.159.45.0 255.255.255.0 207.95.6.101 1/1 1 S
60 209.159.46.0 255.255.255.0 207.95.6.101 1/1 1 S
```

This example shows all the routes for networks beginning with 209.159. The mask value and **longer** parameter specify the range of network addresses to be displayed. In this example, all routes within the range 209.159.0.0 – 209.159.255.255 are listed.

The **summary** option displays a summary of the information in the IP route table. The following is an example of the output from this command.

Example

```
Brocade# show ip route summary

IP Routing Table - 35 entries:
  6 connected, 28 static, 0 RIP, 1 OSPF, 0 BGP, 0 ISIS, 0 MPLS
Number of prefixes:
 /0: 1 /16: 27 /22: 1 /24: 5 /32: 1
```

Syntax: show ip route summary

In this example, the IP route table contains 35 entries. Of these entries, 6 are directly connected devices, 28 are static routes, and 1 route was calculated through OSPF. One of the routes has a zero-bit mask (this is the default route), 27 have a 22-bit mask, 5 have a 24-bit mask, and 1 has a 32-bit mask.

The following table lists the information displayed by the **show ip route** command.

TABLE 187 CLI display of IP route table

Field	Description
Destination	The destination network of the route.
NetMask	The network mask of the destination address.
Gateway	The next-hop router. An asterisk (*) next to the next-hop router indicates that it is one of multiple Equal-Cost Multi-Path (ECMP) next hops for a given route. The asterisk will initially appear next to the first next hop for each route with multiple ECMP next hops. If the ARP entry for the <i>next hop</i> * ages out or is cleared, then the next packet to be routed through the Brocade device whose destination matches that route can cause the asterisk to move to the next hop down the list of ECMP next hops for that route. This means that if the <i>next hop</i> * goes down, the asterisk can move to another next hop with equal cost.
Port	The port through which this router sends packets to reach the route's destination.
Cost	The route's cost.
Type	The route type, which can be one of the following: <ul style="list-style-type: none"> • B – The route was learned from BGP. • D – The destination is directly connected to this Layer 3 Switch. • R – The route was learned from RIP. • S – The route is a static route. • * – The route and next-hop gateway are resolved through the ip default-network setting. • O – The route is an OSPF route. Unless you use the ospf option to display the route table, "O" is used for all OSPF routes. If you do use the ospf option, the following type codes are used: <ul style="list-style-type: none"> • O – OSPF intra area route (within the same area). • IA – The route is an OSPF inter area route (a route that passes from one area into another). • E1 – The route is an OSPF external type 1 route. • E2 – The route is an OSPF external type 2 route.

Clearing IP routes

If needed, you can clear the entire route table or specific individual routes.

To clear all routes from the IP route table, enter the following command.

```
Brocade# clear ip route
```

To clear route 209.157.22.0/24 from the IP routing table, enter the **clear ip route** command.

```
Brocade# clear ip route 209.157.22.0/24
```

Syntax: **clear ip route** [*<ip-addr>* *<ip-mask>*]

or

Syntax: **clear ip route** [*<ip-addr>/<mask-bits>*]

Displaying IP traffic statistics

To display IP traffic statistics, enter the **show ip traffic** command at any CLI level.

```
Brocade# show ip traffic
```

```
IP Statistics
```

```
  139 received, 145 sent, 0 forwarded
  0 filtered, 0 fragmented, 0 reassembled, 0 bad header
  0 no route, 0 unknown proto, 0 no buffer, 0 other errors
```

```
ICMP Statistics
```

```
Received:
```

```
  0 total, 0 errors, 0 unreachable, 0 time exceed
  0 parameter, 0 source quench, 0 redirect, 0 echo,
  0 echo reply, 0 timestamp, 0 timestamp reply, 0 addr mask
  0 addr mask reply, 0 irdp advertisement, 0 irdp solicitation
```

```
Sent:
```

```
  0 total, 0 errors, 0 unreachable, 0 time exceed
  0 parameter, 0 source quench, 0 redirect, 0 echo,
  0 echo reply, 0 timestamp, 0 timestamp reply, 0 addr mask
  0 addr mask reply, 0 irdp advertisement, 0 irdp solicitation
```

```
UDP Statistics
```

```
  1 received, 0 sent, 1 no port, 0 input errors
```

```
TCP Statistics
```

```
  0 active opens, 0 passive opens, 0 failed attempts
  0 active resets, 0 passive resets, 0 input errors
  138 in segments, 141 out segments, 4 retransmission
```

```
RIP Statistics
```

```
  0 requests sent, 0 requests received
  0 responses sent, 0 responses received
  0 unrecognized, 0 bad version, 0 bad addr family, 0 bad req format
  0 bad metrics, 0 bad resp format, 0 resp not from rip port
  0 resp from loopback, 0 packets rejected
```

The **show ip traffic** command displays the following information.

TABLE 188 CLI display of IP traffic statistics – Layer 3 Switch

Field	Description
IP statistics	
received	The total number of IP packets received by the device.
sent	The total number of IP packets originated and sent by the device.
forwarded	The total number of IP packets received by the device and forwarded to other devices.
filtered	The total number of IP packets filtered by the device.
fragmented	The total number of IP packets fragmented by this device to accommodate the MTU of this device or of another device.
reassembled	The total number of fragmented IP packets that this device re-assembled.
bad header	The number of IP packets dropped by the device due to a bad packet header.
no route	The number of packets dropped by the device because there was no route.
unknown proto	The number of packets dropped by the device because the value in the Protocol field of the packet header is unrecognized by this device.
no buffer	This information is used by Brocade customer support.
other errors	The number of packets dropped due to error types other than those listed above.
ICMP statistics	
The ICMP statistics are derived from RFC 792, "Internet Control Message Protocol", RFC 950, "Internet Standard Subnetting Procedure", and RFC 1256, "ICMP Router Discovery Messages". Statistics are organized into Sent and Received. The field descriptions below apply to each.	
total	The total number of ICMP messages sent or received by the device.
errors	This information is used by Brocade customer support.
unreachable	The number of Destination Unreachable messages sent or received by the device.
time exceed	The number of Time Exceeded messages sent or received by the device.
parameter	The number of Parameter Problem messages sent or received by the device.
source quench	The number of Source Quench messages sent or received by the device.
redirect	The number of Redirect messages sent or received by the device.
echo	The number of Echo messages sent or received by the device.
echo reply	The number of Echo Reply messages sent or received by the device.
timestamp	The number of Timestamp messages sent or received by the device.
timestamp reply	The number of Timestamp Reply messages sent or received by the device.
addr mask	The number of Address Mask Request messages sent or received by the device.
addr mask reply	The number of Address Mask Replies messages sent or received by the device.
irdp advertisement	The number of ICMP Router Discovery Protocol (IRDP) Advertisement messages sent or received by the device.
irdp solicitation	The number of IRDP Solicitation messages sent or received by the device.
UDP statistics	

TABLE 188 CLI display of IP traffic statistics – Layer 3 Switch (Continued)

Field	Description
received	The number of UDP packets received by the device.
sent	The number of UDP packets sent by the device.
no port	The number of UDP packets dropped because they did not have a valid UDP port number.
input errors	This information is used by Brocade customer support.
TCP statistics	
The TCP statistics are derived from RFC 793, "Transmission Control Protocol".	
active opens	The number of TCP connections opened by sending a TCP SYN to another device.
passive opens	The number of TCP connections opened by this device in response to connection requests (TCP SYNs) received from other devices.
failed attempts	This information is used by Brocade customer support.
active resets	The number of TCP connections this device reset by sending a TCP RESET message to the device at the other end of the connection.
passive resets	The number of TCP connections this device reset because the device at the other end of the connection sent a TCP RESET message.
input errors	This information is used by Brocade customer support.
in segments	The number of TCP segments received by the device.
out segments	The number of TCP segments sent by the device.
retransmission	The number of segments that this device retransmitted because the retransmission timer for the segment had expired before the device at the other end of the connection had acknowledged receipt of the segment.
RIP statistics	
The RIP statistics are derived from RFC 1058, "Routing Information Protocol".	
requests sent	The number of requests this device has sent to another RIP router for all or part of its RIP routing table.
requests received	The number of requests this device has received from another RIP router for all or part of this device RIP routing table.
responses sent	The number of responses this device has sent to another RIP router request for all or part of this device RIP routing table.
responses received	The number of responses this device has received to requests for all or part of another RIP router routing table.
unrecognized	This information is used by Brocade customer support.
bad version	The number of RIP packets dropped by the device because the RIP version was either invalid or is not supported by this device.
bad addr family	The number of RIP packets dropped because the value in the Address Family Identifier field of the packet header was invalid.
bad req format	The number of RIP request packets this router dropped because the format was bad.
bad metrics	This information is used by Brocade customer support.
bad resp format	The number of responses to RIP request packets dropped because the format was bad.
resp not from rip port	This information is used by Brocade customer support.

TABLE 188 CLI display of IP traffic statistics – Layer 3 Switch (Continued)

Field	Description
resp from loopback	The number of RIP responses received from loopback interfaces.
packets rejected	This information is used by Brocade customer support.

Displaying IP information – Layer 2 Switches

You can display the following IP configuration information statistics on Layer 2 Switches:

- Global IP settings – refer to [“Displaying global IP configuration information”](#) on page 1080.
- ARP entries – refer to [“Displaying ARP entries”](#) on page 1081.
- IP traffic statistics – refer to [“To display IP traffic statistics on a Layer 2 Switch, enter the show ip traffic command at any CLI level.”](#) on page 1082.

Displaying global IP configuration information

To display the Layer 2 Switch IP address and default gateway, enter the **show ip** command.

```
Brocade# show ip

Switch IP address: 192.168.1.2

Subnet mask: 255.255.255.0

Default router address: 192.168.1.1
TFTP server address: None
Configuration filename: None
Image filename: None
```

Syntax: show ip

This display shows the following information.

TABLE 189 CLI display of global IP configuration information – Layer 2 Switch

Field	Description
IP configuration	
Switch IP address	The management IP address configured on the Layer 2 Switch. Specify this address for Telnet or Web management access.
Subnet mask	The subnet mask for the management IP address.
Default router address	The address of the default gateway, if you specified one.
Most recent TFTP access	
TFTP server address	The IP address of the most-recently contacted TFTP server, if the switch has contacted a TFTP server since the last time the software was reloaded or the switch was rebooted.

TABLE 189 CLI display of global IP configuration information – Layer 2 Switch

Field	Description
Configuration filename	The name under which the Layer 2 Switch startup-config file was uploaded or downloaded during the most recent TFTP access.
Image filename	The name of the Layer 2 Switch flash image (system software file) that was uploaded or downloaded during the most recent TFTP access.

Displaying ARP entries

To display the entries the Layer 2 Switch has placed in its ARP cache, enter the **show arp** command from any level of the CLI.

```
Brocade# show arp
```

```
Total Arp Entries : 1, maximum capacity: 1000
No.
1      IP           Mac           Port Age VlanId
      192.168.1.170  0010.5a11.d042   7    0     1
```

Syntax: show arp

This display shows the following information.

TABLE 190 CLI display of ARP cache

Field	Description
Total ARP Entries	The number of entries in the ARP cache.
Maximum capacity	The total number of ARP entries supported on the device.
IP	The IP address of the device.
Mac	The MAC address of the device. NOTE: If the MAC address is all zeros, the entry is for the default gateway, but the Layer 2 Switch does not have a link to the gateway.
Port	The port on which the entry was learned.
Age	The number of minutes the entry has remained unused. If this value reaches the ARP aging period, the entry is removed from the cache.
VlanId	The VLAN the port that learned the entry is in. NOTE: If the MAC address is all zeros, this field shows a random VLAN ID, since the Layer 2 Switch does not yet know which port the device for this entry is attached to.

Displaying IP traffic statistics

To display IP traffic statistics on a Layer 2 Switch, enter the **show ip traffic** command at any CLI level.

```
Brocade# show ip traffic

IP Statistics
  27 received, 24 sent
  0 fragmented, 0 reassembled, 0 bad header
  0 no route, 0 unknown proto, 0 no buffer, 0 other errors

ICMP Statistics
Received:
  0 total, 0 errors, 0 unreachable, 0 time exceed
  0 parameter, 0 source quench, 0 redirect, 0 echo,
  0 echo reply, 0 timestamp, 0 timestamp rely, 0 addr mask
  0 addr mask reply, 0 irdp advertisement, 0 irdp solicitation
Sent:
  0 total, 0 errors, 0 unreachable, 0 time exceed
  0 parameter, 0 source quench, 0 redirect, 0 echo,
  0 echo reply, 0 timestamp, 0 timestamp rely, 0 addr mask
  0 addr mask reply, 0 irdp advertisement, 0 irdp solicitation

UDP Statistics
  0 received, 0 sent, 0 no port, 0 input errors

TCP Statistics
  1 current active tcbs, 4 tcbs allocated, 0 tcbs freed 0 tcbs protected
  0 active opens, 0 passive opens, 0 failed attempts
  0 active resets, 0 passive resets, 0 input errors
  27 in segments, 24 out segments, 0 retransmission
```

Syntax: show ip traffic

The **show ip traffic** command displays the following information.

TABLE 191 CLI display of IP traffic statistics – Layer 2 Switch

Field	Description
IP statistics	
received	The total number of IP packets received by the device.
sent	The total number of IP packets originated and sent by the device.
fragmented	The total number of IP packets fragmented by this device to accommodate the MTU of this device or of another device.
reassembled	The total number of fragmented IP packets that this device re-assembled.
bad header	The number of IP packets dropped by the device due to a bad packet header.
no route	The number of packets dropped by the device because there was no route.
unknown proto	The number of packets dropped by the device because the value in the Protocol field of the packet header is unrecognized by this device.
no buffer	This information is used by Brocade customer support.
other errors	The number of packets that this device dropped due to error types other than the types listed above.

TABLE 191 CLI display of IP traffic statistics – Layer 2 Switch (Continued)

Field	Description
ICMP statistics	
The ICMP statistics are derived from RFC 792, “Internet Control Message Protocol”, RFC 950, “Internet Standard Subnetting Procedure”, and RFC 1256, “ICMP Router Discovery Messages”. Statistics are organized into Sent and Received. The field descriptions below apply to each.	
total	The total number of ICMP messages sent or received by the device.
errors	This information is used by Brocade customer support.
unreachable	The number of Destination Unreachable messages sent or received by the device.
time exceed	The number of Time Exceeded messages sent or received by the device.
parameter	The number of Parameter Problem messages sent or received by the device.
source quench	The number of Source Quench messages sent or received by the device.
redirect	The number of Redirect messages sent or received by the device.
echo	The number of Echo messages sent or received by the device.
echo reply	The number of Echo Reply messages sent or received by the device.
timestamp	The number of Timestamp messages sent or received by the device.
timestamp reply	The number of Timestamp Reply messages sent or received by the device.
addr mask	The number of Address Mask Request messages sent or received by the device.
addr mask reply	The number of Address Mask Replies messages sent or received by the device.
irdp advertisement	The number of ICMP Router Discovery Protocol (IRDP) Advertisement messages sent or received by the device.
irdp solicitation	The number of IRDP Solicitation messages sent or received by the device.
UDP statistics	
received	The number of UDP packets received by the device.
sent	The number of UDP packets sent by the device.
no port	The number of UDP packets dropped because the packet did not contain a valid UDP port number.
input errors	This information is used by Brocade customer support.
TCP statistics	
The TCP statistics are derived from RFC 793, “Transmission Control Protocol”.	
current active tcbs	The number of TCP Control Blocks (TCBs) that are currently active.
tcbs allocated	The number of TCBs that have been allocated.
tcbs freed	The number of TCBs that have been freed.
tcbs protected	This information is used by Brocade customer support.
active opens	The number of TCP connections opened by this device by sending a TCP SYN to another device.
passive opens	The number of TCP connections opened by this device in response to connection requests (TCP SYNs) received from other devices.
failed attempts	This information is used by Brocade customer support.
active resets	The number of TCP connections this device reset by sending a TCP RESET message to the device at the other end of the connection.

TABLE 191 CLI display of IP traffic statistics – Layer 2 Switch (Continued)

Field	Description
passive resets	The number of TCP connections this device reset because the device at the other end of the connection sent a TCP RESET message.
input errors	This information is used by Brocade customer support.
in segments	The number of TCP segments received by the device.
out segments	The number of TCP segments sent by the device.
retransmission	The number of segments that this device retransmitted because the retransmission timer for the segment had expired before the device at the other end of the connection had acknowledged receipt of the segment.

Disabling IP checksum check

NOTE

This command is supported on FastIron X Series IPv4 devices only.

The **disable-hw-ip-checksum-check** command traps a packet with bad checksum to the CPU. Previously, if the packet processor detected a packet with, for example, the checksum 0xFFFF, it would treat it as a bad checksum even if it was correct and it would drop the packet. Now, the command **disable-hw-ip-checksum-check** traps the packet at the CPU and if the checksum is correct, it forwards the packet.

To set disable hardware ip checksum check for all ports, enter the following command.

```
Brocade# )# disable-hw-ip-checksum-check
disable-ip-header-check set for all ports
```

To clear disable hardware ip checksum check on all ports, enter the following command.

```
Brocade# )# no disable-hw-ip-checksum-check ethernet 13
disable-hw-ip-checksum-check cleared for ports the 13 to 24
```

To set disable hardware ip checksum check on for example, port range 0-12, enter the following command.

```
Brocade# ))# disable-hw-ip-checksum-check ethernet 2
disable-ip-header-check set for ports ethe 1 to 12
```

To set disable hardware ip checksum check on, for example, port range 13-24, enter the following command.

```
Brocade# ))# disable-hw-ip-checksum-check ethernet 22
disable-ip-header-check set for ports ethe 13 to 24
```

To clear disable hardware ip checksum check on, for example, port range 13-24, enter the following command.

```
Brocade# )# no disable-hw-ip-checksum-check ethernet 13  
disable-hw-ip-checksum-check cleared for ports the 13 to 24
```

NOTE

The port range could be any consecutive range, it may not necessarily be a decimal number.

Syntax: [no] **disable-hw-ip-checksum-check ethernet** <portnum>

NOTE

This command only functions on the IPv4 platform.

Disabling IP checksum check

Spanning Tree Protocol

[Table 192](#) lists the individual Brocade FastIron switches and the Spanning Tree Protocol (STP) features they support. These features are supported in the Layer 2, base Layer 3, edge Layer 3, and full Layer 3 software images, except where explicitly noted.

TABLE 192 Supported STP features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
802.1s Multiple Spanning Tree	Yes	Yes	Yes	Yes	Yes
802.1W Rapid Spanning Tree (RSTP)	Yes	Yes	Yes	Yes	Yes
802.1D Spanning Tree Support	Yes	Yes	Yes	Yes	Yes
Enhanced IronSpan support includes Fast Port Span, Fast Uplink Span, and Single-instance Span	Yes	Yes	Yes	Yes	Yes
FastIron Layer 2 devices (switches) support up to 254 spanning tree instances for VLANs.	Yes	Yes	Yes	Yes	32 for ICX 6430
Layer 3 devices (routers) support up to 254 spanning tree instances for VLANs.	Yes	Yes	Yes	Yes	ICX 6450 only
PVST/PVST+ compatibility	Yes	Yes	Yes	Yes	Yes
PVRST+ compatibility	Yes	Yes	Yes	Yes	Yes
BPDU Guard	Yes	Yes	Yes	Yes	Yes
Root Guard	Yes	Yes	Yes	Yes	Yes
Error disable recovery	Yes	Yes	Yes	Yes	Yes

STP overview

The Spanning Tree Protocol (STP) eliminates Layer 2 loops in networks, by selectively blocking some ports and allowing other ports to forward traffic, based on global (bridge) and local (port) parameters you can configure.

STP related features, such as RSTP and PVST, extend the operation of standard STP, enabling you to fine-tune standard STP and avoid some of its limitations.

You can enable or disable STP on a global basis (for the entire device), a port-based VLAN basis (for the individual Layer 2 broadcast domain), or an individual port basis.

Configuration procedures are provided for the standard STP bridge and port parameters as well as Brocade features listed in [Table 198](#).

Standard STP parameter configuration

Brocade Layer 2 Switches and Layer 3 Switches support standard STP as described in the IEEE 802.1D specification. STP is enabled by default on Layer 2 Switches but disabled by default on Layer 3 Switches.

By default, each port-based VLAN on a Brocade device runs a separate spanning tree (a separate instance of STP). A Brocade device has one port-based VLAN (VLAN 1) by default that contains all the device ports. Thus, by default each Brocade device has one spanning tree. However, if you configure additional port-based VLANs on a Brocade device, then each of those VLANs on which STP is enabled and VLAN 1 all run separate spanning trees.

If you configure a port-based VLAN on the device, the VLAN has the same STP state as the default STP state on the device. Thus, on Layer 2 Switches, new VLANs have STP enabled by default. On Layer 3 Switches, new VLANs have STP disabled by default. You can enable or disable STP in each VLAN separately. In addition, you can enable or disable STP on individual ports.

STP parameters and defaults

[Table 193](#) lists the default STP states for Brocade devices.

TABLE 193 Default STP states

Device type	Default STP type	Default STP state	Default STP state of new VLANs ¹
Layer 2 Switch	MSTP ²	Enabled	Enabled
Layer 3 Switch	MSTP	Disabled	Disabled

1. When you create a port-based VLAN, the new VLAN STP state is the same as the default STP state on the device. The new VLAN does not inherit the STP state of the default VLAN.

2. MSTP stands for "Multiple Spanning Tree Protocol". In this type of STP, each port-based VLAN, including the default VLAN, has its own spanning tree. References in this documentation to "STP" apply to MSTP. The Single Spanning Tree Protocol (SSTP) is another type of STP. SSTP includes all VLANs on which STP is enabled in a single spanning tree. Refer to ["Single Spanning Tree \(SSTP\)"](#) on page 1151.

[Table 194](#) lists the default STP bridge parameters. The bridge parameters affect the entire spanning tree. If you are using MSTP, the parameters affect the VLAN. If you are using SSTP, the parameters affect all VLANs that are members of the single spanning tree.

TABLE 194 Default STP bridge parameters

Parameter	Description	Default and valid values
Forward Delay	The period of time spent by a port in the listening and learning state before moving on to the learning or forwarding state, respectively. The forward delay value is also used for the age time of dynamic entries in the filtering database, when a topology change occurs.	15 seconds Possible values: 4 – 30 seconds
Maximum Age	The interval a bridge will wait for a configuration BPDU from the root bridge before initiating a topology change.	20 seconds Possible values: 6 – 40 seconds

TABLE 194 Default STP bridge parameters (Continued)

Parameter	Description	Default and valid values
Hello Time	The interval of time between each configuration BPDU sent by the root bridge.	2 seconds Possible values: 1 – 10 seconds
Priority	A parameter used to identify the root bridge in a spanning tree (instance of STP). The bridge with the lowest value has the highest priority and is the root. A higher numerical value means a lower priority; thus, the highest priority is 0.	32768 Possible values: 0 – 65535

NOTE

If you plan to change STP bridge timers, Brocade recommends that you stay within the following ranges, from section 8.10.2 of the IEEE STP specification.

$$2 * (\text{forward_delay} - 1) \geq \text{max_age}$$

$$\text{max_age} \geq 2 * (\text{hello_time} + 1)$$

Table 195 lists the default STP port parameters. The port parameters affect individual ports and are separately configurable on each port.

TABLE 195 Default STP port parameters

Parameter	Description	Default and valid values
Priority	The preference that STP gives this port relative to other ports for forwarding traffic out of the spanning tree. A higher numerical value means a lower priority.	128 Possible values: 0 – 240 (configurable in increments of 16)
Path Cost	The cost of using the port to reach the root bridge. When selecting among multiple links to the root bridge, STP chooses the link with the lowest path cost and blocks the other paths. Each port type has its own default STP path cost.	10 Mbps – 100 100 Mbps – 19 Gbps – 4 10 Gbps – 2 Possible values are 0 – 65535

Enabling or disabling the Spanning Tree Protocol (STP)

STP is *enabled* by default on devices running Layer 2 code. STP is *disabled* by default on devices running Layer 3 code.

You can enable or disable STP on the following levels:

- **Globally** – Affects all ports and port-based VLANs on the device.
- **Port-based VLAN** – Affects all ports within the specified port-based VLAN. When you enable or disable STP within a port-based VLAN, the setting overrides the global setting. Thus, you can enable STP for the ports within a port-based VLAN even when STP is globally disabled, or disable the ports within a port-based VLAN when STP is globally enabled.
- **Individual port** – Affects only the individual port. However, if you change the STP state of the primary port in a trunk group, the change affects all ports in the trunk group.

NOTE

The CLI converts the STP groups into topology groups when you save the configuration. For backward compatibility, you can still use the STP group commands. However, the CLI converts the commands into the topology group syntax. Likewise, the **show stp-group** command displays STP topology groups.

Enabling or disabling STP globally

Use the following method to enable or disable STP on a device on which you have not configured port-based VLANs.

NOTE

When you configure a VLAN, the VLAN inherits the global STP settings. However, once you begin to define a VLAN, you can no longer configure standard STP parameters globally using the CLI. From that point on, you can configure STP only within individual VLANs.

To enable STP for all ports in all VLANs on a Brocade device, enter the **spanning-tree** command.

```
Brocade(config)#spanning-tree
```

The **spanning-tree** command enables a separate spanning tree in each VLAN, including the default VLAN.

Syntax: [no] spanning-tree

Enabling or disabling STP in a port-based VLAN

Use the following procedure to disable or enable STP on a device on which you have configured a port-based VLAN. Changing the STP state in a VLAN affects only that VLAN.

To enable STP for all ports in a port-based VLAN, enter commands such as the following.

```
Brocade(config)#vlan 10
Brocade(config-vlan-10)#spanning-tree
```

Syntax: [no] spanning-tree

Enabling or disabling STP on an individual port

Use the following procedure to disable or enable STP on an individual port.

NOTE

If you change the STP state of the primary port in a trunk group, it affects all ports in the trunk group.

To enable STP on an individual port, enter commands such as the following.

```
Brocade(config)#interface 1/1
Brocade(config-if-e1000-1/1)#spanning-tree
```

Syntax: [no] spanning-tree

Changing STP bridge and port parameters

[Table 194](#) on page 1088 and [Table 195](#) on page 1089 list the default STP parameters. If you need to change the default value for an STP parameter, use the following procedures.

Changing STP bridge parameters

NOTE

If you plan to change STP bridge timers, Brocade recommends that you stay within the following ranges, from section 8.10.2 of the IEEE STP specification.

$$2 * (\text{forward_delay} - 1) \geq \text{max_age}$$

$$\text{max_age} \geq 2 * (\text{hello_time} + 1)$$

To change a STP bridge priority on a Brocade device to the highest value to make the device the root bridge, enter the following command.

```
Brocade(config)#spanning-tree priority 0
```

The command in this example changes the priority on a device on which you have not configured port-based VLANs. The change applies to the default VLAN. If you have configured a port-based VLAN on the device, you can configure the parameters only at the configuration level for individual VLANs. Enter commands such as the following.

```
Brocade(config)#vlan 20
Brocade(config-vlan-20)#spanning-tree priority 0
```

To make this change in the default VLAN, enter the following commands.

```
Brocade(config)#vlan 1
Brocade(config-vlan-1)#spanning-tree priority 0
```

Syntax: [no] spanning-tree [forward-delay <value>] | [hello-time <value>] | [maximum-age <value>] | [priority <value>]

The **forward-delay** <value> parameter specifies the forward delay and can be a value from 4 – 30 seconds. The default is 15 seconds.

NOTE

You can configure a Brocade device for faster convergence (including a shorter forward delay) using Fast Span or Fast Uplink Span. Refer to [“STP feature configuration”](#) on page 1103.

The **hello-time** <value> parameter specifies the hello time and can be a value from 1 – 10 seconds. The default is 2 seconds.

NOTE

This parameter applies only when this device or VLAN is the root bridge for its spanning tree.

The **maximum-age** <value> parameter specifies the amount of time the device waits for receipt of a configuration BPDU from the root bridge before initiating a topology change. You can specify from 6 – 40 seconds. The default is 20 seconds.

The **priority** <value> parameter specifies the priority and can be a value from 0 – 65535. A higher numerical value means a lower priority. Thus, the highest priority is 0. The default is 32768.

You can specify some or all of these parameters on the same command line. If you specify more than one parameter, you must specify them in the order shown above, from left to right.

Changing STP port parameters

To change the path and priority costs for a port, enter commands such as the following.

```
Brocade(config)#vlan 10
Brocade(config-vlan-10)#spanning-tree ethernet 5 path-cost 15 priority 64
```

Syntax: **spanning-tree ethernet** <port> **path-cost** <value> | **priority** <value> | **disable** | **enable**

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

The **path-cost** <value> parameter specifies the port cost as a path to the spanning tree root bridge. STP prefers the path with the lowest cost. You can specify a value from 0 – 65535.

The default depends on the port type:

- 10 Mbps – 100
- 100 Mbps – 19
- Gbps – 4
- 10 Gbps – 2
- The **priority** <value> parameter specifies the preference that STP gives this port relative to other ports for forwarding traffic out of the spanning tree. If you are upgrading a device that has a configuration saved under an earlier software release, and the configuration contains a value from 0 – 7 for a port STP priority, the software changes the priority to the default when you save the configuration while running the new release.

The **disable** | **enable** parameter disables or re-enables STP on the port. The STP state change affects only this VLAN. The port STP state in other VLANs is not changed.

NOTE

When you enable or disable STP auto negotiated combo ports on FESX devices, the ports may flap for a few seconds before the link is up

STP protection enhancement

STP protection provides the ability to prohibit an end station from initiating or participating in an STP topology change.

The 802.1W Spanning Tree Protocol (STP) detects and eliminates logical loops in a redundant network by selectively blocking some data paths (ports) and allowing only the best data paths to forward traffic.

In an STP environment, switches, end stations, and other Layer 2 devices use Bridge Protocol Data Units (BPDUs) to exchange information that STP will use to determine the best path for data flow. When a Layer 2 device is powered ON and connected to the network, or when a Layer 2 device goes down, it sends out an STP BPDU, triggering an STP topology change.

In some instances, it is unnecessary for a connected device, such as an end station, to initiate or participate in an STP topology change. In this case, you can enable the STP Protection feature on the Brocade port to which the end station is connected. STP Protection disables the connected device ability to initiate or participate in an STP topology change, by dropping all BPDUs received from the connected device.

Enabling STP protection

You can enable STP Protection on a per-port basis.

To prevent an end station from initiating or participating in STP topology changes, enter the following command at the Interface level of the CLI.

```
Brocade#(config) interface e 2
Brocade#(config-if-e1000-2)#stp-protect
```

This command causes the port to drop STP BPDUs sent from the device on the other end of the link.

Syntax: `[no] stp-protect`

Enter the **no** form of the command to disable STP protection on the port.

Clearing BPDU drop counters

For each port that has STP Protection enabled, the Brocade device counts and records the number of dropped BPDUs. You can use CLI commands to clear the BPDU drop counters for all ports on the device, or for a specific port on the device.

To clear the BPDU drop counters for all ports on the device that have STP Protection enabled, enter the following command at the Global CONFIG level of the CLI.

```
Brocade(config)#clear stp-protect-statistics
```

To clear the BPDU drop counter for a specific port that has STP Protection enabled, enter the following command at the Global CONFIG level of the CLI.

```
Brocade#clear stp-protect-statistics e 2
```

Syntax: `clear stp-protect-statistics [ethernet [<port>]] | [ethernet [<port>]]`

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Viewing the STP Protection Configuration

You can view the STP Protection configuration for all ports on a device, or for a specific port only. The **show stp-protect** command output shows the port number on which STP Protection is enabled, and the number of BPDUs dropped by each port.

To view the STP Protection configuration for all ports on the device, enter the following command at any level of the CLI.

Standard STP parameter configuration

```
Brocade#show stp-protect
Port ID          BPDU Drop Count
3                478
5                213
6                0
12              31
```

To view STP Protection configuration for a specific port, enter the following command at any level of the CLI.

```
Brocade#show stp-protect e 3
STP-protect is enabled on port 3. BPDU drop count is 478
```

If you enter the **show stp-protect** command for a port that does not have STP protection enabled, the following message displays on the console.

```
Brocade#show stp-protect e 4
STP-protect is not enabled on port 4.
```

Syntax: **show stp-protect** [**ethernet** <port>]

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Displaying STP information

You can display the following Spanning Tree Protocol (STP) information:

- All the global and interface STP settings
- CPU utilization statistics
- Detailed STP information for each interface
- STP state information for a port-based VLAN
- STP state information for an individual interface

Displaying STP information for an entire device

To display STP information, enter the following command at any level of the CLI.

```
Brocade#show span
```

```
VLAN 1 BPDU cam_index is 3 and the Master DMA Are(HEX)
STP instance owned by VLAN 1
```

Global STP (IEEE 802.1D) Parameters:

VLAN ID	Root ID	Root Cost	Root Port	Prio rity Hex	Max Age sec	He- llo sec	Ho- ld sec	Fwd dly sec	Last Chang sec	Chg cnt	Bridge Address
1	800000e0804d4a00	0	Root	8000	20	2	1	15	689	1	00e0804d4a00

Port STP Parameters:

Port Num	Prio rity Hex	Path Cost	State	Fwd Trans	Design Cost	Designated Root	Designated Bridge
1	80	19	FORWARDING	1	0	800000e0804d4a00	800000e0804d4a00
2	80	0	DISABLED	0	0	0000000000000000	0000000000000000
3	80	0	DISABLED	0	0	0000000000000000	0000000000000000
4	80	0	DISABLED	0	0	0000000000000000	0000000000000000
5	80	19	FORWARDING	1	0	800000e0804d4a00	800000e0804d4a00
6	80	19	BLOCKING	0	0	800000e0804d4a00	800000e0804d4a00
7	80	0	DISABLED	0	0	0000000000000000	0000000000000000

<lines for remaining ports excluded for brevity>

Syntax: `show span [vlan <vlan-id>] | [pvst-mode] | [<num>] | [detail [vlan <vlan-id> [ethernet [<port>] | <num>]]]`

The **vlan <vlan-id>** parameter displays STP information for the specified port-based VLAN.

The **pvst-mode** parameter displays STP information for the device Per VLAN Spanning Tree (PVST+) compatibility configuration. Refer to [“PVST/PVST+ compatibility”](#) on page 1157

Specify the **port** variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

The **<num>** parameter displays only the entries after the number you specify. For example, on a device with three port-based VLANs, if you enter 1, then information for the second and third VLANs is displayed, but information for the first VLAN is not displayed. Information is displayed according to VLAN number, in ascending order. The entry number is not the same as the VLAN number. For example, if you have port-based VLANs 1, 10, and 2024, then the command output has three STP entries. To display information for VLANs 10 and 2024 only, enter **show span 1**.

The **detail** parameter and its additional optional parameters display detailed information for individual ports. Refer to [“Displaying detailed STP information for each interface”](#) on page 1099.

The **show span** command shows the following information.

TABLE 196 CLI display of STP information

Field	Description
Global STP parameters	
VLAN ID	The port-based VLAN that contains this spanning tree (instance of STP). VLAN 1 is the default VLAN. If you have not configured port-based VLANs on this device, all STP information is for VLAN 1.
Root ID	The ID assigned by STP to the root bridge for this spanning tree.
Root Cost	The cumulative cost from this bridge to the root bridge. If this device is the root bridge, then the root cost is 0.
Root Port	The port on this device that connects to the root bridge. If this device is the root bridge, then the value is "Root" instead of a port number.
Priority Hex	This device or VLAN STP priority. The value is shown in hexadecimal format. NOTE: If you configure this value, specify it in decimal format. Refer to "Changing STP bridge parameters" on page 1091.
Max age sec	The number of seconds this device or VLAN waits for a configuration BPDU from the root bridge before deciding the root has become unavailable and performing a reconvergence.
Hello sec	The interval between each configuration BPDU sent by the root bridge.
Hold sec	The minimum number of seconds that must elapse between transmissions of consecutive Configuration BPDUs on a port.
Fwd dly sec	The number of seconds this device or VLAN waits following a topology change and consequent reconvergence.
Last Chang sec	The number of seconds since the last time a topology change occurred.
Chg cnt	The number of times the topology has changed since this device was reloaded.
Bridge Address	The STP address of this device or VLAN. NOTE: If this address is the same as the Root ID, then this device or VLAN is the root bridge for its spanning tree.
Port STP parameters	
Port Num	The port number.
Priority Hex	The port STP priority, in hexadecimal format. NOTE: If you configure this value, specify it in decimal format. Refer to "Changing STP port parameters" on page 1092.
Path Cost	The port STP path cost.

TABLE 196 CLI display of STP information (Continued)

Field	Description
State	<p>The port STP state. The state can be one of the following:</p> <ul style="list-style-type: none"> • BLOCKING – STP has blocked Layer 2 traffic on this port to prevent a loop. The device or VLAN can reach the root bridge using another port, whose state is FORWARDING. When a port is in this state, the port does not transmit or receive user frames, but the port does continue to receive STP BPDUs. • DISABLED – The port is not participating in STP. This can occur when the port is disconnected or STP is disabled on the port. • FORWARDING – STP is allowing the port to send and receive frames. • LISTENING – STP is responding to a topology change and this port is listening for a BPDU from neighboring bridges in order to determine the new topology. No user frames are transmitted or received during this state. • LEARNING – The port has passed through the LISTENING state and will change to the FORWARDING state, depending on the results of STP reconvergence. The port does not transmit or receive user frames during this state. However, the device can learn the MAC addresses of frames that the port receives during this state and make corresponding entries in the MAC table.
Fwd Trans	The number of times STP has changed the state of this port between BLOCKING and FORWARDING.
Design Cost	The cost to the root bridge as advertised by the designated bridge that is connected to this port. If the designated bridge is the root bridge itself, then the cost is 0. The identity of the designated bridge is shown in the Design Bridge field.
Designated Root	The root bridge as recognized on this port. The value is the same as the root bridge ID listed in the Root ID field.
Designated Bridge	The designated bridge to which this port is connected. The designated bridge is the device that connects the network segment on the port to the root bridge.

Displaying CPU utilization statistics

You can display CPU utilization statistics for STP and the IP protocols.

To display CPU utilization statistics for STP for the previous one-second, one-minute, five-minute, and fifteen-minute intervals, enter the following command at any level of the CLI.

```

Brocade#show process cpu
Process Name    5Sec(%)    1Min(%)    5Min(%)    15Min(%)    Runtime(ms)
ARP             0.01       0.03       0.09       0.22        9
BGP             0.04       0.06       0.08       0.14       13
GVRP           0.00       0.00       0.00       0.00        0
ICMP           0.00       0.00       0.00       0.00        0
IP             0.00       0.00       0.00       0.00        0
OSPF           0.00       0.00       0.00       0.00        0
RIP            0.00       0.00       0.00       0.00        0
STP            0.00       0.03       0.04       0.07        4
VRRP           0.00       0.00       0.00       0.00        0

```

If the software has been running less than 15 minutes (the maximum interval for utilization statistics), the command indicates how long the software has been running. Here is an example.

Standard STP parameter configuration

```
Brocade#show process cpu
The system has only been up for 6 seconds.
Process Name    5Sec(%)    1Min(%)    5Min(%)    15Min(%)    Runtime(ms)
ARP              0.01        0.00        0.00        0.00         0
BGP              0.00        0.00        0.00        0.00         0
GVRP             0.00        0.00        0.00        0.00         0
ICMP             0.01        0.00        0.00        0.00         1
IP               0.00        0.00        0.00        0.00         0
OSPF             0.00        0.00        0.00        0.00         0
RIP              0.00        0.00        0.00        0.00         0
STP              0.00        0.00        0.00        0.00         0
VRRP            0.00        0.00        0.00        0.00         0
```

To display utilization statistics for a specific number of seconds, enter a command such as the following.

```
Brocade#show process cpu 2
Statistics for last 1 sec and 80 ms
Process Name    Sec(%)    Time(ms)
ARP             0.00        0
BGP             0.00        0
GVRP            0.00        0
ICMP            0.01        1
IP              0.00        0
OSPF            0.00        0
RIP             0.00        0
STP             0.01        0
VRRP           0.00        0
```

When you specify how many seconds' worth of statistics you want to display, the software selects the sample that most closely matches the number of seconds you specified. In this example, statistics are requested for the previous two seconds. The closest sample available is actually for the previous 1 second plus 80 milliseconds.

Syntax: `show process cpu [<num>]`

The `<num>` parameter specifies the number of seconds and can be from 1 – 900. If you use this parameter, the command lists the usage statistics only for the specified number of seconds. If you do not use this parameter, the command lists the usage statistics for the previous one-second, one-minute, five-minute, and fifteen-minute intervals.

Displaying the STP state of a port-based VLAN

When you display information for a port-based VLAN, that information includes the STP state of the VLAN.

To display information for a port-based VLAN, enter a command such as the following at any level of the CLI. The STP state is shown in bold type in this example.

```
Brocade#show vlans
```

```
Total PORT-VLAN entries: 2
Maximum PORT-VLAN entries: 16
```

```
legend: [S=Slot]
```

```
PORT-VLAN 1, Name DEFAULT-VLAN, Priority level0, Spanning tree On
Untagged Ports: (S3)  1  2  3  4  5  6  7  8  9 10 11 12 13 14 15 16
Untagged Ports: (S3) 17 18 19 20 21 22 23 24
Untagged Ports: (S4)  2  3  4  5  6  7  8  9 10 11 12 13 14 15 16 17
Untagged Ports: (S4) 18 19 20 21 22 23 24
Tagged Ports: None
Uplink Ports: None
```

```
PORT-VLAN 2, Name greenwell, Priority level0, Spanning tree Off
Untagged Ports: (S1)  1  2  3  4  5  6  7  8
Untagged Ports: (S4)  1
Tagged Ports: None
Uplink Ports: None
```

Syntax: `show vlan [<vlan-id> | ethernet <port>]`

The `<vlan-id>` parameter specifies a VLAN for which you want to display the configuration information.

The `ethernet <port>` parameter specifies a port. If you use this parameter, the command lists all the VLAN memberships for the port. Specify the `port` variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Displaying detailed STP information for each interface

To display the detailed STP information, enter the following command at any level of the CLI.

```
Brocade#show span detail
=====
VLAN 1 - MULTIPLE SPANNING TREE (MSTP) ACTIVE
=====
Bridge identifier      - 0x800000e0804d4a00
Active global timers - Hello: 0

Port 1/1 is FORWARDING
  Port - Path cost: 19, Priority: 128, Root: 0x800000e052a9bb00
  Designated - Bridge: 0x800000e052a9bb00, Interface: 1, Path cost: 0
  Active Timers - None
  BPDUs - Sent: 11, Received: 0
Port 1/2 is DISABLED
Port 1/3 is DISABLED
Port 1/4 is DISABLED
<lines for remaining ports excluded for brevity>
```

NOTE

The line in the above output, **VLAN 1 - MULTIPLE SPANNING TREE (MSTP) ACTIVE**, is not the 802.1s standard. It is the same Global STP (IEEE 802.1D) type as shown in the output of the **show span** CLI command.

If a port is disabled, the only information shown by this command is “DISABLED”. If a port is enabled, this display shows the following information.

Syntax: **show span detail** [**vlan** <vlan-id>] [**ethernet** <port>] <num>]

The **vlan** <vlan-id> parameter specifies a VLAN.

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

The <num> parameter specifies the number of VLANs you want the CLI to skip before displaying detailed STP information. For example, if the device has six VLANs configured (VLAN IDs 1, 2, 3, 99, 128, and 256) and you enter the command **show span detail 4**, detailed STP information is displayed for VLANs 128 and 256 only.

NOTE

If the configuration includes VLAN groups, the **show span detail** command displays the master VLANs of each group but not the member VLANs within the groups. However, the command does indicate that the VLAN is a master VLAN. The **show span detail vlan** <vlan-id> command displays the information for the VLAN even if it is a member VLAN. To list all the member VLANs within a VLAN group, enter the **show vlan-group** [<group-id>] command.

The **show span detail** command shows the following information.

TABLE 197 CLI display of detailed STP information for ports

Field	Description
Active Spanning Tree protocol	<p>The VLAN that contains the listed ports and the active Spanning Tree protocol. The STP type can be one of the following:</p> <ul style="list-style-type: none"> • MULTIPLE SPANNING TREE (MSTP) • GLOBAL SINGLE SPANNING TREE (SSTP) <p>NOTE: If STP is disabled on a VLAN, the command displays the following message instead: “Spanning-tree of port-vlan <vlan-id> is disabled.”</p>
Bridge identifier	The STP identity of this device.
Active global timers	<p>The global STP timers that are currently active, and their current values. The following timers can be listed:</p> <ul style="list-style-type: none"> • Hello – The interval between Hello packets. This timer applies only to the root bridge. • Topology Change (TC) – The amount of time during which the topology change flag in Hello packets will be marked, indicating a topology change. This timer applies only to the root bridge. • Topology Change Notification (TCN) – The interval between Topology Change Notification packets sent by a non-root bridge toward the root bridge. This timer applies only to non-root bridges.

TABLE 197 CLI display of detailed STP information for ports (Continued)

Field	Description
Port number and STP state	<p>The internal port number and the port STP state.</p> <p>The internal port number is one of the following:</p> <ul style="list-style-type: none"> • The port interface number, if the port is the designated port for the LAN. • The interface number of the designated port from the received BPDU, if the interface is not the designated port for the LAN. <p>The state can be one of the following:</p> <ul style="list-style-type: none"> • BLOCKING – STP has blocked Layer 2 traffic on this port to prevent a loop. The device or VLAN can reach the root bridge using another port, whose state is FORWARDING. When a port is in this state, the port does not transmit or receive user frames, but the port does continue to receive STP BPDUs. • DISABLED – The port is not participating in STP. This can occur when the port is disconnected or STP is administratively disabled on the port. • FORWARDING – STP is allowing the port to send and receive frames. • LISTENING – STP is responding to a topology change and this port is listening for a BPDU from neighboring bridges in order to determine the new topology. No user frames are transmitted or received during this state. • LEARNING – The port has passed through the LISTENING state and will change to the BLOCKING or FORWARDING state, depending on the results of STP reconvergence. The port does not transmit or receive user frames during this state. However, the device can learn the MAC addresses of frames that the port receives during this state and make corresponding entries in the MAC table. <p>NOTE: If the state is DISABLED, no further STP information is displayed for the port.</p>
Port Path cost	The STP path cost for the port.
Port Priority	This STP priority for the port. The value is shown as a hexadecimal number.
Root	The ID assigned by STP to the root bridge for this spanning tree.
Designated Bridge	The MAC address of the designated bridge to which this port is connected. The designated bridge is the device that connects the network segment on the port to the root bridge.
Designated Port	The port number sent from the designated bridge.
Designated Path Cost	The cost to the root bridge as advertised by the designated bridge that is connected to this port. If the bridge is the root bridge itself, then the cost is 0. The identity of the designated bridge is shown in the Designated Bridge field.
Active Timers	<p>The current values for the following timers, if active:</p> <ul style="list-style-type: none"> • Message age – The number of seconds this port has been waiting for a hello message from the root bridge. • Forward delay – The number of seconds that have passed since the last topology change and consequent reconvergence. • Hold time – The number of seconds that have elapsed since transmission of the last Configuration BPDU.
BPDUs Sent and Received	The number of BPDUs sent and received on this port since the software was reloaded.

Displaying detailed STP information for a single port in a specific VLAN

Enter a command such as the following to display STP information for an individual port in a specific VLAN.

```
Brocade#show span detail vlan 1 ethernet 7/1
Port 7/1 is FORWARDING
  Port - Path cost: 19, Priority: 128, Root: 0x800000e052a9bb00
  Designated - Bridge: 0x800000e052a9bb00, Interface: 7, Path cost: 0
  Active Timers - None
  BPDUs - Sent: 29, Received: 0
```

Syntax: `show span detail [vlan <vlan-id> ethernet <port>`

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Displaying STP state information for an individual interface

To display STP state information for an individual port, you can use the methods in [“Displaying STP information for an entire device”](#) on page 1095 or [“Displaying detailed STP information for each interface”](#) on page 1099. You also can display STP state information for a specific port using the following method.

To display information for a specific port, enter a command such as the following at any level of the CLI.

```
Brocade#show interface ethernet 3/11

FastEthernet3/11 is up, line protocol is up
  Hardware is FastEthernet, address is 00e0.52a9.bb49 (bia 00e0.52a9.bb49)
  Configured speed auto, actual 100Mbit, configured duplex fdx, actual fdx
  Member of L2 VLAN ID 1, port is untagged, port state is FORWARDING
  STP configured to ON, priority is level0, flow control enabled
  mirror disabled, monitor disabled
  Not member of any active trunks
  Not member of any configured trunks
  No port name
  MTU 1518 bytes, encapsulation ethernet
  5 minute input rate: 352 bits/sec, 0 packets/sec, 0.00% utilization
  5 minute output rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
  1238 packets input, 79232 bytes, 0 no buffer
  Received 686 broadcasts, 0 runts, 0 giants
  0 input errors, 0 CRC, 0 frame, 0 ignored
  529 multicast
  918 packets output, 63766 bytes, 0 underruns
  0 output errors, 0 collisions
```

The STP information is shown in bold type in this example.

Syntax: `show interfaces [ethernet <port>] | [loopback <num>] | [slot <slot-num>] | [ve <num>] | [brief]`

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

You also can display the STP states of all ports by entering the **show interface brief** command such as the following, which uses the **brief** parameter.

```
Brocade#show interface brief
```

Port	Link	State	Dupl	Speed	Trunk	Tag	Priori	MAC	Name
1/1	Down	None	None	None	None	No	level0	00e0.52a9.bb00	
1/2	Down	None	None	None	None	No	level0	00e0.52a9.bb01	
1/3	Down	None	None	None	None	No	level0	00e0.52a9.bb02	
1/4	Down	None	None	None	None	No	level0	00e0.52a9.bb03	
1/5	Down	None	None	None	None	No	level0	00e0.52a9.bb04	
1/6	Down	None	None	None	None	No	level0	00e0.52a9.bb05	
1/7	Down	None	None	None	None	No	level0	00e0.52a9.bb06	
1/8	Down	None	None	None	None	No	level0	00e0.52a9.bb07	
. some rows omitted for brevity									
3/10	Down	None	None	None	None	No	level0	00e0.52a9.bb4a	
3/11	Up	Forward	Full	100M	None	No	level0	00e0.52a9.bb49	

In the example above, only one port, 3/11, is forwarding traffic toward the root bridge.

STP feature configuration

Spanning Tree Protocol (STP) features extend the operation of standard STP, enabling you to fine-tune standard STP and avoid some of its limitations.

This section describes how to configure these parameters on Brocade Layer 3 Switches using the CLI.

Fast port span

When STP is running on a device, message forwarding is delayed during the spanning tree recalculation period following a topology change. The STP forward delay parameter specifies the period of time a bridge waits before forwarding data packets. The forward delay controls the listening and learning periods of STP reconvergence. You can configure the forward delay to a value from 4 – 30 seconds. The default is 15 seconds. Thus, using the standard forward delay, convergence requires 30 seconds (15 seconds for listening and an additional 15 seconds for learning) when the default value is used.

This slow convergence is undesirable and unnecessary in some circumstances. The Fast Port Span feature allows certain ports to enter the forwarding state in four seconds. Specifically, Fast Port Span allows faster convergence on ports that are attached to end stations and thus do not present the potential to cause Layer 2 forwarding loops. Because the end stations cannot cause forwarding loops, they can safely go through the STP state changes (blocking to listening to learning to forwarding) more quickly than is allowed by the standard STP convergence time. Fast Port Span performs the convergence on these ports in four seconds (two seconds for listening and two seconds for learning).

In addition, Fast Port Span enhances overall network performance in the following ways:

- Fast Port Span reduces the number of STP topology change notifications on the network. When an end station attached to a Fast Span port comes up or down, the Brocade device does not generate a topology change notification for the port. In this situation, the notification is unnecessary since a change in the state of the host does not affect the network topology.
- Fast Port Span eliminates unnecessary MAC cache aging that can be caused by topology change notifications. Bridging devices age out the learned MAC addresses in their MAC caches if the addresses are unrefreshed for a given period of time, sometimes called the MAC aging interval. When STP sends a topology change notification, devices that receive the notification use the value of the STP forward delay to quickly age out their MAC caches. For example, if a device normal MAC aging interval is 5 minutes, the aging interval changes temporarily to the value of the forward delay (for example, 15 seconds) in response to an STP topology change.

In normal STP, the accelerated cache aging occurs even when a single host goes up or down. Because Fast Port Span does not send a topology change notification when a host on a Fast Port Span port goes up or down, the unnecessary cache aging that can occur in these circumstances under normal STP is eliminated.

Fast Port Span is a system-wide parameter and is enabled by default. Thus, when you boot a device, all the ports that are attached only to end stations run Fast Port Span. For ports that are not eligible for Fast Port Span, such as ports connected to other networking devices, the device automatically uses the normal STP settings. If a port matches any of the following criteria, the port is ineligible for Fast Port Span and uses normal STP instead:

- The port is 802.1Q tagged
- The port is a member of a trunk group
- The port has learned more than one active MAC address
- An STP Configuration BPDU has been received on the port, thus indicating the presence of another bridge on the port.

You also can explicitly exclude individual ports from Fast Port Span if needed. For example, if the only uplink ports for a wiring closet switch are Gbps ports, you can exclude the ports from Fast Port Span.

Disabling and re-enabling fast port span

Fast Port Span is a system-wide parameter and is enabled by default. Therefore, all ports that are eligible for Fast Port Span use it.

To disable or re-enable Fast Port Span, enter the following commands.

```
Brocade(config)#no fast port-span
Brocade(config)#write memory
```

Syntax: [no] fast port-span

NOTE

The **fast port-span** command has additional parameters that let you exclude specific ports. These parameters are shown in the following section.

To re-enable Fast Port Span, enter the following commands.

```
Brocade(config)#fast port-span
Brocade(config)#write memory
```

Excluding specific ports from fast port span

To exclude a port from Fast Port Span while leaving Fast Port Span enabled globally, enter commands such as the following.

```
Brocade(config)#fast port-span exclude ethernet 1
Brocade(config)#write memory
```

To exclude a set of ports from Fast Port Span, enter commands such as the following.

```
Brocade(config)#fast port-span exclude ethernet 1 ethernet 2 ethernet 3
Brocade(config)#write memory
```

To exclude a contiguous (unbroken) range of ports from Fast Span, enter commands such as the following.

```
Brocade(config)#fast port-span exclude ethernet 1 to 24
Brocade(config)#write memory
```

Syntax: **[no] fast port-span [exclude ethernet <port> [ethernet <port>] | to [<port>]]**

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

To re-enable Fast Port Span on a port, enter a command such as the following.

```
Brocade(config)#no fast port-span exclude ethernet 1
Brocade(config)#write memory
```

This command re-enables Fast Port Span on port 1 only and does not re-enable Fast Port Span on other excluded ports. You also can re-enable Fast Port Span on a list or range of ports using the syntax shown above this example.

To re-enable Fast Port Span on all excluded ports, disable and then re-enable Fast Port Span by entering the following commands.

```
Brocade(config)#no fast port-span
Brocade(config)#fast port-span
Brocade(config)#write memory
```

Disabling and then re-enabling Fast Port Span clears the exclude settings and thus enables Fast Port Span on all eligible ports. To make sure Fast Port Span remains enabled on the ports following a system reset, save the configuration changes to the startup-config file after you re-enable Fast Port Span. Otherwise, when the system resets, those ports will again be excluded from Fast Port Span.

Fast Uplink Span

The Fast Port Span feature described in the previous section enhances STP performance for end stations. The Fast Uplink Span feature enhances STP performance for wiring closet switches with redundant uplinks. Using the default value for the standard STP forward delay, convergence following a transition from an active link to a redundant link can take 30 seconds (15 seconds for listening and an additional 15 seconds for learning).

You can use the Fast Uplink Span feature on a Brocade device deployed as a wiring closet switch to decrease the convergence time for the uplink ports to another device to just one second. The new Uplink port directly goes to forward mode (bypassing listening and learning modes). The wiring closet switch must be a Brocade device but the device at the other end of the link can be a Brocade device or another vendor's switch.

Configuration of the Fast Uplink Span feature takes place entirely on the Brocade device. To configure the Fast Uplink Span feature, specify a group of ports that have redundant uplinks on the wiring closet switch (Brocade device). If the active link becomes unavailable, the Fast Uplink Span feature transitions the forwarding to one of the other redundant uplink ports in just one second. All Fast Uplink Span-enabled ports are members of a single Fast Uplink Span group.

NOTE

To avoid the potential for temporary bridging loops, Brocade recommends that you use the Fast Uplink feature only for wiring closet switches (switches at the edge of the network cloud). In addition, enable the feature only on a group of ports intended for redundancy, so that at any given time only one of the ports is expected to be in the forwarding state.

NOTE

When the wiring closet switch (Brocade device) first comes up or when STP is first enabled, the uplink ports still must go through the standard STP state transition without any acceleration. This behavior guards against temporary routing loops as the switch tries to determine the states for all the ports. Fast Uplink Span acceleration applies only when a working uplink becomes unavailable.

Active uplink port failure

The active uplink port is the port elected as the root port using the standard STP rules. All other ports in the group are redundant uplink ports. If an active uplink port becomes unavailable, Fast Uplink Span transitions the forwarding of traffic to one of the redundant ports in the Fast Uplink Span group in one second bypassing listening and learning port states.

Switchover to the active uplink port

When a failed active uplink port becomes available again, switchover from the redundant port to the active uplink port is delayed by 30 seconds. The delay allows the remote port to transition to forwarding mode using the standard STP rules. After 30 seconds, the blocked active uplink port begins forwarding in just one second and the redundant port is blocked.

NOTE

Use caution when changing the spanning tree priority. If the switch becomes the root bridge, Fast Uplink Span will be disabled automatically.

Fast Uplink Span Rules for Trunk Groups

If you add a port to a Fast Uplink Span group that is a member of a trunk group, the following rules apply:

- If you add the primary port of a trunk group to the Fast Uplink Span group, all other ports in the trunk group are automatically included in the group. Similarly, if you remove the primary port in a trunk group from the Fast Uplink Span group, the other ports in the trunk group are automatically removed from the Fast Uplink Span group.
- You cannot add a subset of the ports in a trunk group to the Fast Uplink Span group. All ports in a trunk group have the same Fast Uplink Span property, as they do for other port properties.
- If the working trunk group is partially down but not completely down, no switch-over to the backup occurs. This behavior is the same as in the standard STP feature.
- If the working trunk group is completely down, a backup trunk group can go through an accelerated transition only if the following are true:
 - The trunk group is included in the fast uplink group.
 - All other ports except those in this trunk group are either disabled or blocked. The accelerated transition applies to all ports in this trunk group.

When the original working trunk group comes back (partially or fully), the transition back to the original topology is accelerated if the conditions listed above are met.

Configuring a Fast Uplink Port Group

To configure a group of ports for Fast Uplink Span, enter the following commands:

```
Brocade(config)# fast uplink-span ethernet 4/1 to 4/4
Brocade(config)# write memory
```

Syntax: [no] **fast uplink-span** [ethernet <port> [ethernet <port>... | to <port>]]

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

This example configures four ports, 4/1 – 4/4, as a Fast Uplink Span group. In this example, all four ports are connected to a wiring closet switch. Only one of the links is expected to be active at any time. The other links are redundant. For example, if the link on port 4/1 is the active link on the wiring closet switch but becomes unavailable, one of the other links takes over. Because the ports are configured in a Fast Uplink Span group, the STP convergence takes one second instead of taking at least 30 seconds using the standard STP forward delay.

You can add ports to a Fast Uplink Span group by entering the fast uplink-span command additional times with additional ports. The device can have only one Fast Uplink Span group, so all the ports you identify as Fast Uplink Span ports are members of the same group.

STP feature configuration

To remove a Fast Uplink Span group or to remove individual ports from a group, use “no” in front of the appropriate fast uplink-span command. For example, to remove ports 4/3 and 4/4 from the Fast Uplink Span group configured above, enter the following commands:

```
Brocade(config)# no fast uplink-span ethernet 4/3 to 4/4
Brocade(config)# write memory
```

To check the status of ports with Fast Uplink Span enabled.

```
Brocade(config)# show span fast-uplink-span
```

STP instance owned by VLAN 1

Global STP (IEEE 802.1D) Parameters:

VLAN ID	Root ID	Root Cost	Root Port	Prio rity Hex	Max Age sec	He- llo sec	Ho- ld sec	Fwd dly sec	Last Chang sec	Chg cnt	Bridge Address
1	000000c100000001	2	1/3/1	8000	20	2	1	15	65	15	000011111111

Port STP Parameters:

Port Num	Prio rity Hex	Path Cost	State	Fwd Trans	Design Cost	Designated Root	Designated Bridge
1/1/2	80	0	DISABLED	0	0	0000000000000000	0000000000000000
1/1/3	80	0	DISABLED	0	0	0000000000000000	0000000000000000
1/1/4	80	4	FORWARDING	1	2	000000c100000001	8000000011111111
1/1/5	80	0	DISABLED	0	0	0000000000000000	0000000000000000
1/1/6	80	0	DISABLED	0	0	0000000000000000	0000000000000000
1/1/7	80	0	DISABLED	0	0	0000000000000000	0000000000000000
1/1/8	80	0	DISABLED	0	0	0000000000000000	0000000000000000
1/1/9	80	0	DISABLED	0	0	0000000000000000	0000000000000000

Syntax: show span fast-uplink-span

Configuring Fast Uplink Span within a VLAN

You can also configure Fast Uplink Span on the interfaces within a VLAN.

To configure Fast Uplink Span for a VLAN, enter command such as the following.

```
Brocade(config)#vlan 10
Brocade(config-vlan-10)#untag ethernet 8/1 to 8/2
Brocade(config-vlan-10)#fast uplink-span ethernet 8/1 to 8/2
```

Syntax: [no] fast uplink-span ethernet <port-no>

To check the status of Fast Uplink Span for a specified VLAN.

```
Brocade(config-vlan-2)#show span vlan 2 fast-uplink-span
```

STP instance owned by VLAN 2

Global STP (IEEE 802.1D) Parameters:

VLAN ID	Root ID	Root Cost	Root Port	Prio rity Hex	Max Age sec	He- llo sec	Ho- ld sec	Fwd dly sec	Last Chang sec	Chg cnt	Bridge Address
2	800000000111111111	0	Root	8000	20	2	1	15	29596	0	000011111111

Port STP Parameters:

Port Num	Prio rity	Path Cost	State	Fwd Trans	Design Cost	Designated Root	Designated Bridge
	Hex						
1/1/1	80	4	LISTENING	0	0	8000000011111111	8000000011111111

Syntax: `show span vlan <vlan-id> fast-uplink-span`

The VLAN <vlan-id> parameter displays Fast Uplink Span information for the specified VLAN.

802.1W Rapid Spanning Tree (RSTP)

Earlier implementation by Brocade of Rapid Spanning Tree Protocol (RSTP), which was 802.1W Draft 3, provided only a subset of the IEEE 802.1W standard; whereas the 802.1W RSTP feature provides the full standard. The implementation of the 802.1W Draft 3 is referred to as RSTP Draft 3.

RSTP Draft3 will continue to be supported on Brocade devices for backward compatibility. However, customers who are currently using RSTP Draft 3 should migrate to 802.1W.

The 802.1W feature provides rapid traffic reconvergence for point-to-point links within a few milliseconds (0 – 500 milliseconds), following the failure of a bridge or bridge port. This reconvergence occurs more rapidly than the reconvergence provided by the 802.1D Spanning Tree Protocol (STP) or by RSTP Draft 3.

NOTE

This rapid convergence will not occur on ports connected to shared media devices, such as hubs. To take advantage of the rapid convergence provided by 802.1W, make sure to explicitly configure all point-to-point links in a topology.

The convergence provided by the standard 802.1W protocol occurs more rapidly than the convergence provided by previous spanning tree protocols because of the following:

- Classic or legacy 802.1D STP protocol requires a newly selected Root port to go through listening and learning stages before traffic convergence can be achieved. The 802.1D traffic convergence time is calculated using the following formula.

2 x FORWARD_DELAY + BRIDGE_MAX_AGE.

If default values are used in the parameter configuration, convergence can take up to 50 seconds. (In this document STP will be referred to as 802.1D.)

- RSTP Draft 3 works only on bridges that have Alternate ports, which are the precalculated “next best root port”. (Alternate ports provide back up paths to the root bridge.) Although convergence occurs from 0 – 500 milliseconds in RSTP Draft 3, the spanning tree topology reverts to the 802.1D convergence if an Alternate port is not found.
- Convergence in 802.1w bridge is not based on any timer values. Rather, it is based on the explicit handshakes between Designated ports and their connected Root ports to achieve convergence in less than 500 milliseconds.

Bridges and bridge port roles

A bridge in an 802.1W rapid spanning tree topology is assigned as the root bridge if it has the highest priority (lowest bridge identifier) in the topology. Other bridges are referred to as non-root bridges.

Unique roles are assigned to ports on the root and non-root bridges. Role assignments are based on the following information contained in the Rapid Spanning Tree Bridge Packet Data Unit (RST BPDUs):

- Root bridge ID
- Path cost value
- Transmitting bridge ID
- Designated port ID

The 802.1W algorithm uses this information to determine if the RST BPDUs received by a port is superior to the RST BPDUs that the port transmits. The two values are compared in the order as given above, starting with the Root bridge ID. The RST BPDUs with a lower value is considered superior. The superiority and inferiority of the RST BPDUs is used to assign a role to a port.

If the value of the received RST BPDUs is the same as that of the transmitted RST BPDUs, then the port ID in the RST BPDUs are compared. The RST BPDUs with the lower port ID is superior. Port roles are then calculated appropriately.

The port role is included in the BPDUs that it transmits. The BPDUs transmitted by an 802.1W port is referred to as an RST BPDUs, while it is operating in 802.1W mode.

Ports can have one of the following roles:

- **Root** – Provides the lowest cost path to the root bridge from a specific bridge
- **Designated** – Provides the lowest cost path to the root bridge from a LAN to which it is connected
- **Alternate** – Provides an alternate path to the root bridge when the root port goes down
- **Backup** – Provides a backup to the LAN when the Designated port goes down
- **Disabled** – Has no role in the topology

Assignment of port roles

At system start-up, all 802.1W-enabled bridge ports assume a Designated role. Once start-up is complete, the 802.1W algorithm calculates the superiority or inferiority of the RST BPDUs that is received and transmitted on a port.

On a root bridge, each port is assigned a **Designated port** role, except for ports on the same bridge that are physically connected together. In these type of ports, the port that receives the superior RST BPDUs becomes the **Backup port**, while the other port becomes the **Designated port**.

On non-root bridges, ports are assigned as follows:

- The port that receives the RST BPDUs with the lowest path cost from the root bridge becomes the **Root port**.
- If two ports on the same bridge are physically connected, the port that receives the superior RST BPDUs becomes the **Backup port**, while the other port becomes the **Designated port**.
- If a non-root bridge already has a Root port, then the port that receives an RST BPDUs that is superior to those it can transmit becomes the **Alternate port**.
- If the RST BPDUs that a port receives is inferior to the RST BPDUs it transmits, then the port becomes a **Designated port**.
- If the port is down or if 802.1W is disabled on the port, that port is given the role of **Disabled port**. Disabled ports have no role in the topology. However, if 802.1W is enabled on a port with a link down and the link of that port comes up, then that port assumes one of the following port roles: Root, Designated, Alternate, or Backup.

The following example (Figure 126) explains role assignments in a simple RSTP topology.

NOTE

All examples in this document assume that all ports in the illustrated topologies are point-to-point links and are homogeneous (they have the same path cost value) unless otherwise specified.

The topology in Figure 126 contains four bridges. Switch 1 is the root bridge since it has the lowest bridge priority. Switch 2 through Switch 4 are non-root bridges.

FIGURE 126 Simple 802.1W topology

Assignment of ports on Switch 1

All ports on Switch 1, the root bridge, are assigned Designated port roles.

Assignment of ports on Switch 2

Port2 on Switch 2 directly connects to the root bridge; therefore, Port2 is the Root port.

The bridge priority value on Switch 2 is superior to that of Switch 3 and Switch 4; therefore, the ports on Switch 2 that connect to Switch 3 and Switch 4 are given the Designated port role.

Furthermore, Port7 and Port8 on Switch 2 are physically connected. The RST BPDUs transmitted by Port7 are superior to those Port8 transmits. Therefore, Port8 is the Backup port and Port7 is the Designated port.

Assignment of ports on Switch 3

Port2 on Switch 3 directly connects to the Designated port on the root bridge; therefore, it assumes the Root port role.

The root path cost of the RST BPDUs received on Port4/Switch 3 is inferior to the RST BPDUs transmitted by the port; therefore, Port4/Switch 3 becomes the Designated port.

Similarly Switch 3 has a bridge priority value inferior to Switch 2. Port3 on Switch 3 connects to Port 3 on Switch 2. This port will be given the Alternate port role, since a Root port is already established on this bridge.

Assignment of ports on Switch 4

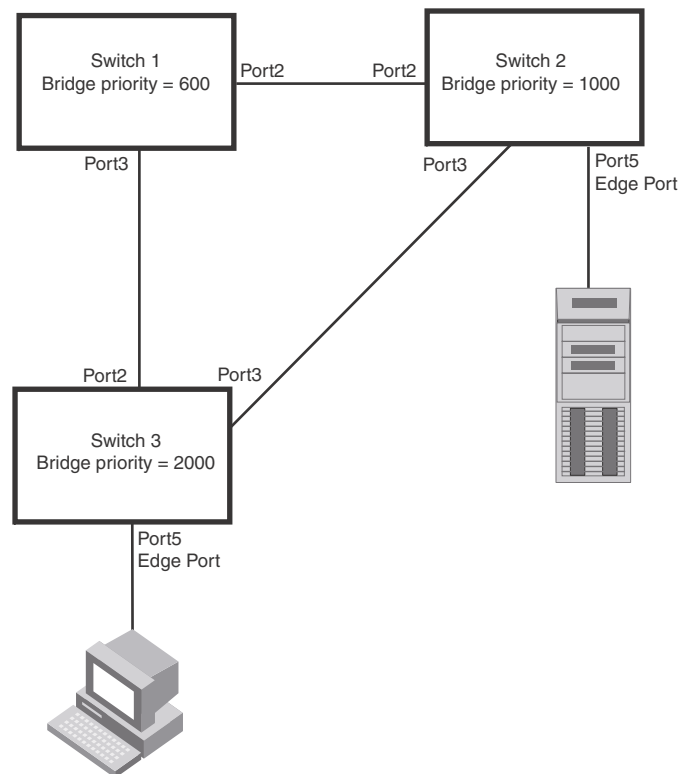

Switch 4 is not directly connected to the root bridge. It has two ports with superior incoming RST BPDUs from two separate LANs: Port3 and Port4. The RST BPDUs received on Port3 are superior to the RST BPDUs received on port 4; therefore, Port3 becomes the Root port and Port4 becomes the Alternate port.

Edge ports and edge port roles

The Brocade implementation of 802.1W allows ports that are configured as Edge ports to be present in an 802.1W topology. (Figure 127). Edge ports are ports of a bridge that connect to workstations or computers. Edge ports do not register any incoming BPDU activities.

Edge ports assume Designated port roles. Port flapping does not cause any topology change events on Edge ports since 802.1W does not consider Edge ports in the spanning tree calculations.

FIGURE 127 Topology with edge ports

However, if any incoming RST BPDUs are received from a previously configured Edge port, 802.1W automatically makes the port as a non-edge port. This is extremely important to ensure a loop free Layer 2 operation since a non-edge port is part of the active RSTP topology.

The 802.1W protocol can auto-detect an Edge port and a non-edge port. An administrator can also configure a port to be an Edge port using the CLI. It is recommended that Edge ports are configured explicitly to take advantage of the Edge port feature, instead of allowing the protocol to auto-detect them.

Point-to-point ports

To take advantage of the 802.1W features, ports on an 802.1W topology should be explicitly configured as point-to-point links using the CLI. Shared media should not be configured as point-to-point links.

NOTE

Configuring shared media or non-point-to-point links as point-to-point links could lead to Layer 2 loops.

The topology in [Figure 128](#) is an example of shared media that should not be configured as point-to-point links. In [Figure 128](#), a port on a bridge communicates or is connected to at least two ports.

FIGURE 128 Example of shared media

Bridge port states

Ports roles can have one of the following states:

- **Forwarding** – 802.1W is allowing the port to send and receive all packets.
- **Discarding** – 802.1W has blocked data traffic on this port to prevent a loop. The device or VLAN can reach the root bridge using another port, whose state is forwarding. When a port is in this state, the port does not transmit or receive data frames, but the port does continue to receive RST BPDUs. This state corresponds to the listening and blocking states of 802.1D.
- **Learning** – 802.1W is allowing MAC entries to be added to the filtering database but does not permit forwarding of data frames. The device can learn the MAC addresses of frames that the port receives during this state and make corresponding entries in the MAC table.
- **Disabled** – The port is not participating in 802.1W. This can occur when the port is disconnected or 802.1W is administratively disabled on the port.

A port on a non-root bridge with the role of Root port is always in a forwarding state. If another port on that bridge assumes the Root port role, then the old Root port moves into a discarding state as it assumes another port role.

A port on a non-root bridge with a Designated role starts in the discarding state. When that port becomes elected to the Root port role, 802.1W quickly places it into a forwarding state. However, if the Designated port is an Edge port, then the port starts and stays in a forwarding state and it cannot be elected as a Root port.

A port with an Alternate or Backup role is always in a discarding state. If the port role changes to Designated, then the port changes into a forwarding state.

If a port on one bridge has a Designated role and that port is connected to a port on another bridge that has an Alternate or Backup role, the port with a Designated role cannot be given a Root port role until two instances of the forward delay timer expires on that port.

Edge port and non-edge port states

As soon as a port is configured as an Edge port using the CLI, it goes into a forwarding state instantly (in less than 100 msec).

When the link to a port comes up and 802.1W detects that the port is an Edge port, that port instantly goes into a forwarding state.

If 802.1W detects that port as a non-edge port, the port state is changed as determined by the result of processing the received RST BPDU. The port state change occurs within four seconds of link up or after two hello timer expires on the port.

Changes to port roles and states

To achieve convergence in a topology, a port role and state changes as it receives and transmits new RST BPDUs. Changes in a port role and state constitute a topology change. Besides the superiority and inferiority of the RST BPDU, bridge-wide and per-port state machines are used to determine a port role as well as a port state. Port state machines also determine when port role and state changes occur.

Port Role Selection state machines

The bridge uses the Port Role Selection state machine to determine if port role changes are required on the bridge. This state machine performs a computation when one of the following events occur:

- New information is received on any port on the bridge
- The timer expires for the current information on a port on the bridge

Each port uses the following state machines:

- **Port Information** – This state machine keeps track of spanning-tree information currently used by the port. It records the origin of the information and ages out any information that was derived from an incoming BPDU.
- **Port Role Transition** – This state machine keeps track of the current port role and transitions the port to the appropriate role when required. It moves the Root port and the Designated port into forwarding states and moves the Alternate and Backup ports into discarding states.
- **Port Transmit** – This state machine is responsible for BPDU transmission. It checks to ensure only the maximum number of BPDUs per hello interval are sent every second. Based on what mode it is operating in, it sends out either legacy BPDUs or RST BPDUs. In this document legacy BPDUs are also referred to as STP BPDUs.

- **Port Protocol Migration** – This state machine deals with compatibility with 802.1D bridges. When a legacy BPDU is detected on a port, this state machine configures the port to transmit and receive legacy BPDUs and operate in the legacy mode.
- **Topology Change** – This state machine detects, generates, and propagates topology change notifications. It acknowledges Topology Change Notice (TCN) messages when operating in 802.1D mode. It also flushes the MAC table when a topology change event takes place.
- **Port State Transition** – This state machine transitions the port to a discarding, learning, or forwarding state and performs any necessary processing associated with the state changes.
- **Port Timers** – This state machine is responsible for triggering any of the state machines described above, based on expiration of specific port timers.

In contrast to the 802.1D standard, the 802.1W standard does not have any bridge specific timers. All timers in the CLI are applied on a per-port basis, even though they are configured under bridge parameters.

802.1W state machines attempt to quickly place the ports into either a forwarding or discarding state. Root ports are quickly placed in forwarding state when both of the following events occur:

- It is assigned to be the Root port.
- It receives an RST BPDU with a proposal flag from a Designated port. The proposal flag is sent by ports with a Designated role when they are ready to move into a forwarding state.

When a the role of Root port is given to another port, the old Root port is instructed to reroot. The old Root port goes into a discarding state and negotiates with its peer port for a new role and a new state. A peer port is the port on the other bridge to which the port is connected. For example, in [Figure 129](#), Port1 of Switch 200 is the peer port of Port2 of Switch 100.

A port with a Designated role is quickly placed into a forwarding state if one of the following occurs:

- The Designated port receives an RST BPDU that contains an agreement flag from a Root port
- The Designated port is an Edge port

However, a Designated port that is attached to an Alternate port or a Backup port must wait until the forward delay timer expires twice on that port while it is still in a Designated role, before it can proceed to the forwarding state.

Backup ports are quickly placed into discarding states.

Alternate ports are quickly placed into discarding states.

A port operating in 802.1W mode may enter a learning state to allow MAC entries to be added to the filtering database; however, this state is transient and lasts only a few milliseconds, if the port is operating in 802.1W mode and if the port meets the conditions for rapid transition.

Handshake mechanisms

To rapidly transition a Designated or Root port into a forwarding state, the Port Role Transition state machine uses handshake mechanisms to ensure loop free operations. It uses one type of handshake if no Root port has been assigned on a bridge, and another type if a Root port has already been assigned.

Handshake when no root port is elected

If a Root port has not been assigned on a bridge, 802.1W uses the *Proposing -> Proposed -> Sync -> Synced -> Agreed* handshake:

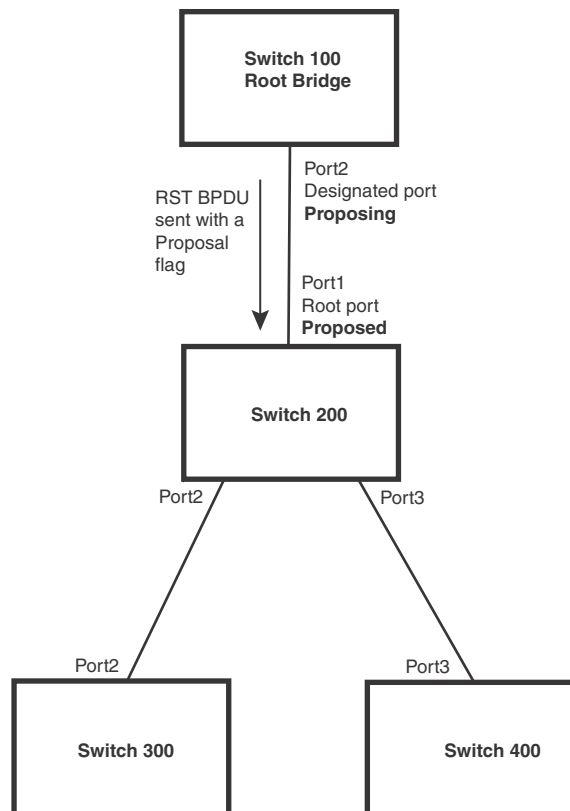

- **Proposing** – The Designated port on the root bridge sends an RST BPDUs packet to its peer port that contains a proposal flag. The proposal flag is a signal that indicates that the Designated port is ready to put itself in a forwarding state (Figure 129). The Designated port continues to send this flag in its RST BPDUs until it is placed in a forwarding state (Figure 132) or is forced to operate in 802.1D mode. (Refer to “Compatibility of 802.1W with 802.1D” on page 1136).
- **Proposed** – When a port receives an RST BPDUs with a proposal flag from the Designated port on its point-to-point link, it asserts the Proposed signal and one of the following occurs (Figure 129):
 - If the RST BPDUs that the port receives is superior to what it can transmit, the port assumes the role of a Root port. (Refer to the section on “Bridges and bridge port roles” on page 1109.)
 - If the RST BPDUs that the port receives is inferior to what it can transmit, then the port is given the role of Designated port.

NOTE

Proposed will never be asserted if the port is connected on a shared media link.

In Figure 129, Port3/Switch 200 is elected as the Root port

FIGURE 129 Proposing and proposed stage

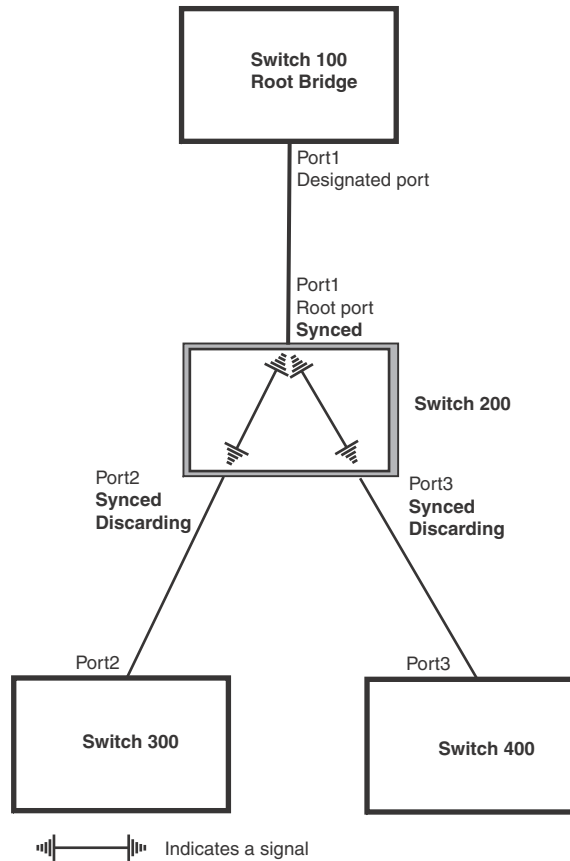

- **Sync** – Once the Root port is elected, it sets a sync signal on all the ports on the bridge. The signal tells the ports to synchronize their roles and states ([Figure 130](#)). Ports that are non-edge ports with a role of Designated port change into a discarding state. These ports have to negotiate with their peer ports to establish their new roles and states.

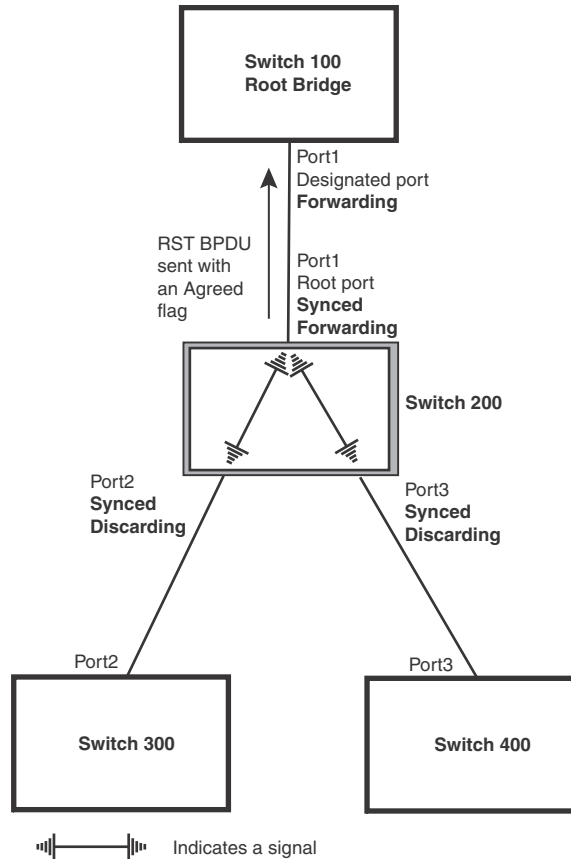

FIGURE 130 Sync stage

- **Synced** – Once the Designated port changes into a discarding state, it asserts a synced signal. Immediately, Alternate ports and Backup ports are synced. The Root port monitors the synced signals from all the bridge ports. Once all bridge ports asserts a synced signal, the Root port asserts its own synced signal ([Figure 131](#)).

FIGURE 131 Synced stage

- **Agreed** – The Root port sends back an RST BPDU containing an agreed flag to its peer Designated port and moves into the forwarding state. When the peer Designated port receives the RST BPDU, it rapidly transitions into a forwarding state.

FIGURE 132 Agree stage

At this point, the handshake mechanism is complete between Switch 100, the root bridge, and Switch 200.

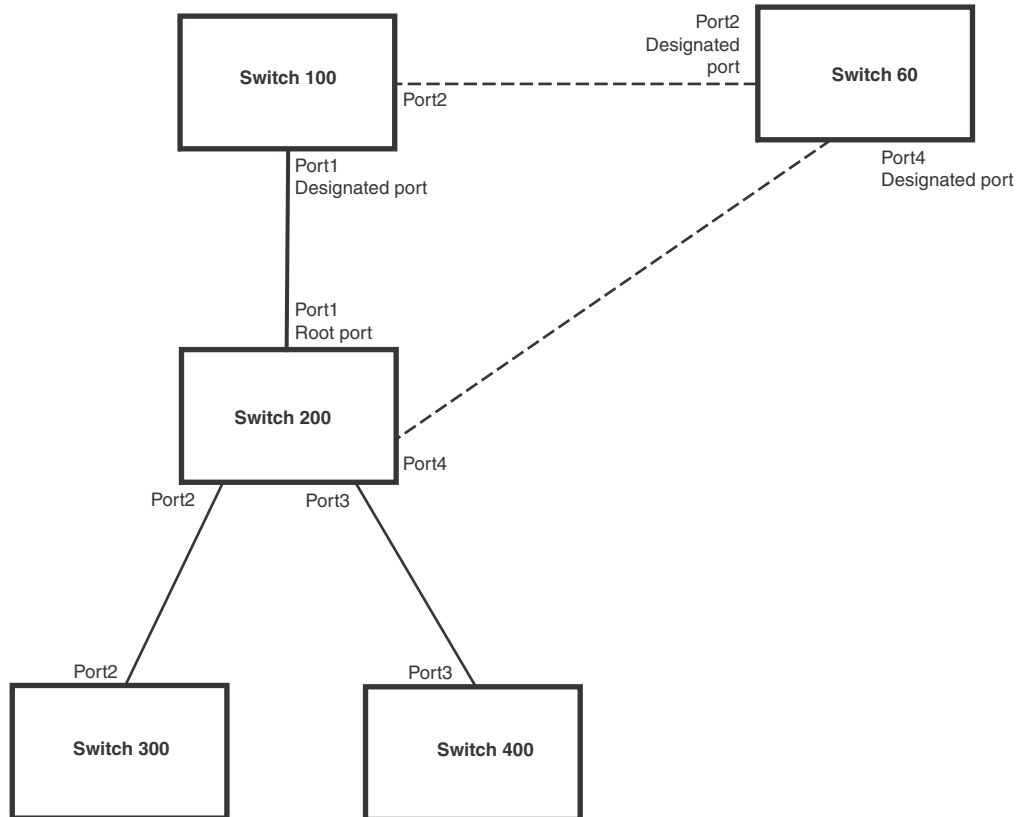

Switch 200 updates the information on the Switch 200 Designated ports (Port2 and Port3) and identifies the new root bridge. The Designated ports send RST BPDUs, containing proposal flags, to their downstream bridges, without waiting for the hello timers to expire on them. This process starts the handshake with the downstream bridges.

For example, Port2/Switch 200 sends an RST BPDU to Port2/Switch 300 that contains a proposal flag. Port2/Switch 300 asserts a proposed signal. Ports in Switch 300 then set sync signals on the ports to synchronize and negotiate their roles and states. Then the ports assert a synced signal and when the Root port in Switch 300 asserts its synced signal, it sends an RST BPDU to Switch 200 with an agreed flag.

This handshake is repeated between Switch 200 and Switch 400 until all Designated and Root ports are in forwarding states.

Handshake when a root port has been elected

If a non-root bridge already has a Root port, 802.1W uses a different type of handshake. For example, in [Figure 133](#), a new root bridge is added to the topology.

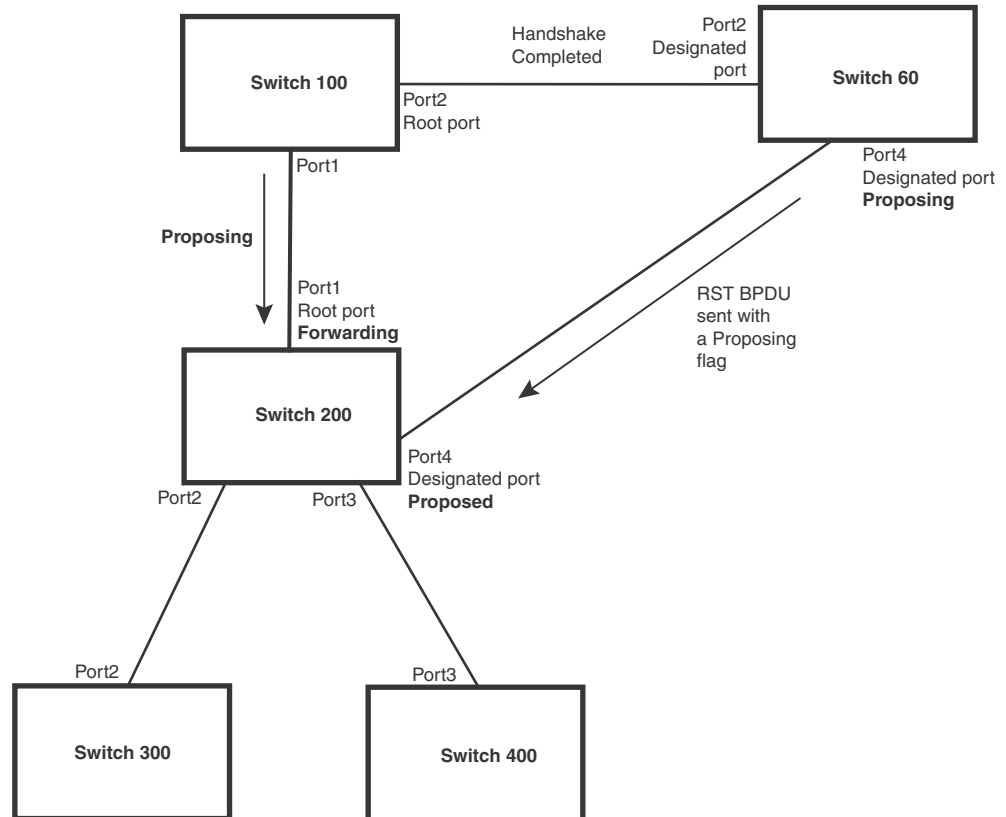

FIGURE 133 Addition of a new root bridge

The handshake that occurs between Switch 60 and Switch 100 follows the one described in the previous section ([“Handshake when no root port is elected”](#) on page 1115). The former root bridge becomes a non-root bridge and establishes a Root port ([Figure 134](#)).

However, since Switch 200 already had a Root port in a forwarding state, 802.1W uses the *Proposing -> Proposed -> Sync* and *Reroot -> Sync* and *Rerooted -> Rerooted* and *Synced -> Agreed handshake*:

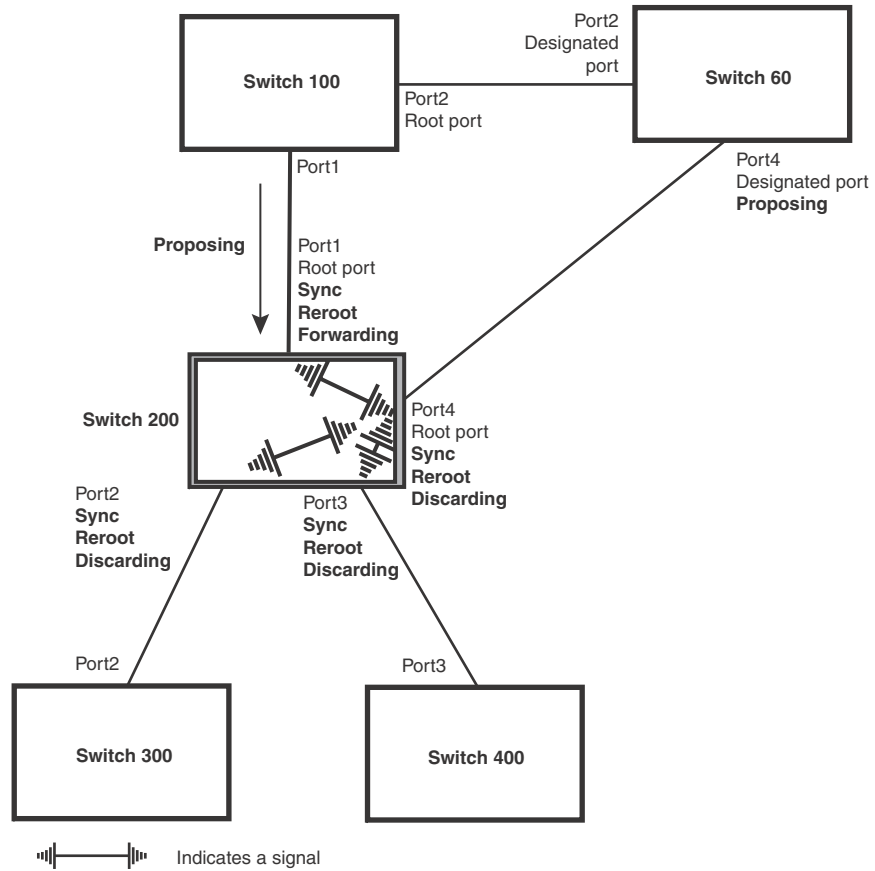

- Proposing and Proposed** – The Designated port on the new root bridge (Port4/Switch 60) sends an RST BPDU that contains a proposing signal to Port4/Switch 200 to inform the port that it is ready to put itself in a forwarding state (Figure 134). 802.1W algorithm determines that the RST BPDU that Port4/Switch 200 received is superior to what it can generate, so Port4/Switch 200 assumes a Root port role.

FIGURE 134 New root bridge sending a proposal flag

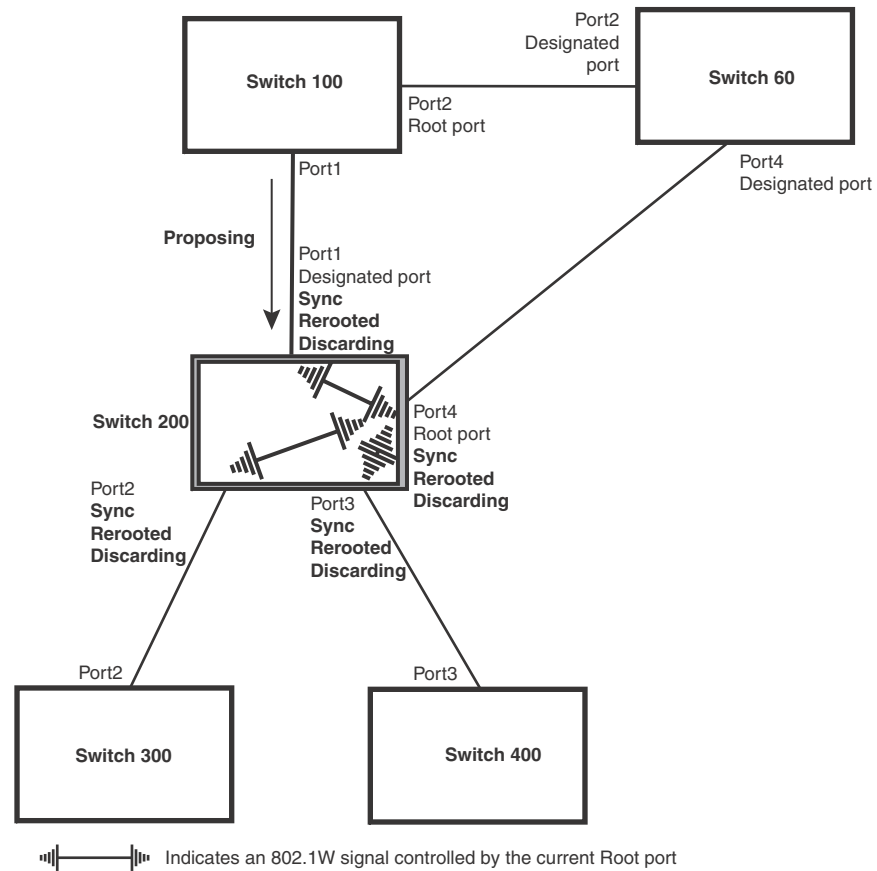

- **Sync and Reroot** – The Root port then asserts a sync and a reroot signal on all the ports on the bridge. The signal tells the ports that a new Root port has been assigned and they are to renegotiate their new roles and states. The other ports on the bridge assert their sync and reroot signals. Information about the old Root port is discarded from all ports. Designated ports change into discarding states ([Figure 135](#)).

FIGURE 135 Sync and reroot

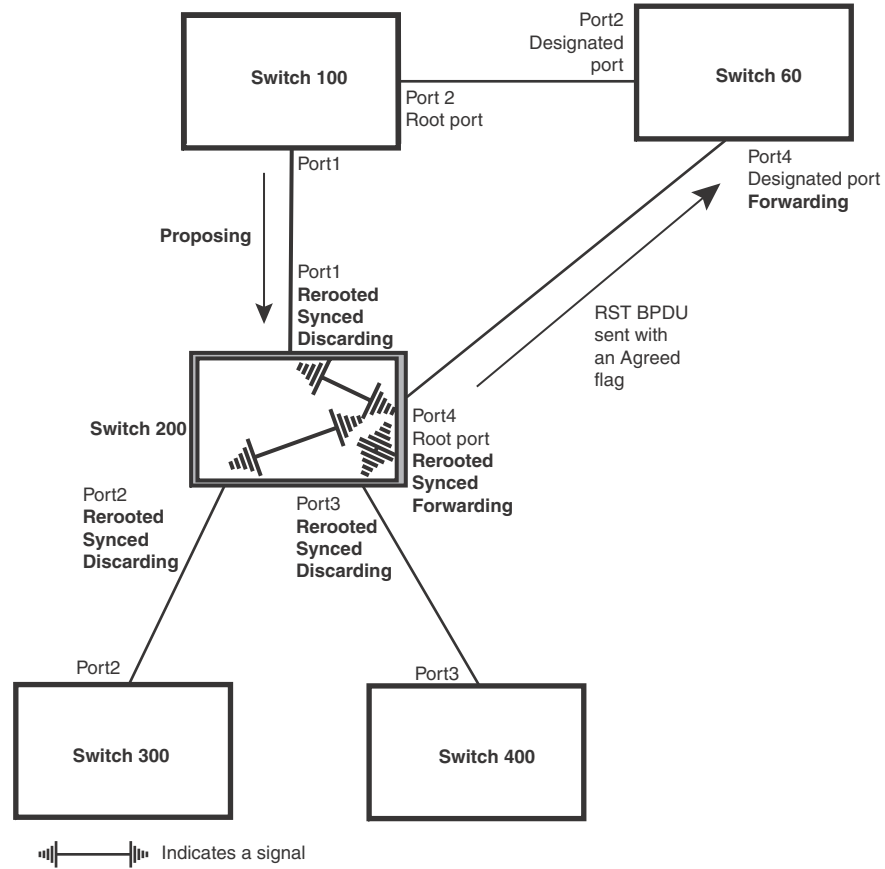

- **Sync and Rerooted** – When the ports on Switch 200 have completed the reroot phase, they assert their sync signals and continue to assert their sync signals as they continue in their discarding states. They also continue to negotiate their roles and states with their peer ports (Figure 136).

FIGURE 136 Sync and rerooted

- **Synced and Agree** – When all the ports on the bridge assert their synced signals, the new Root port asserts its own synced signal and sends an RST BPDU to Port4/Switch 60 that contains an agreed flag (Figure 136). The Root port also moves into a forwarding state.

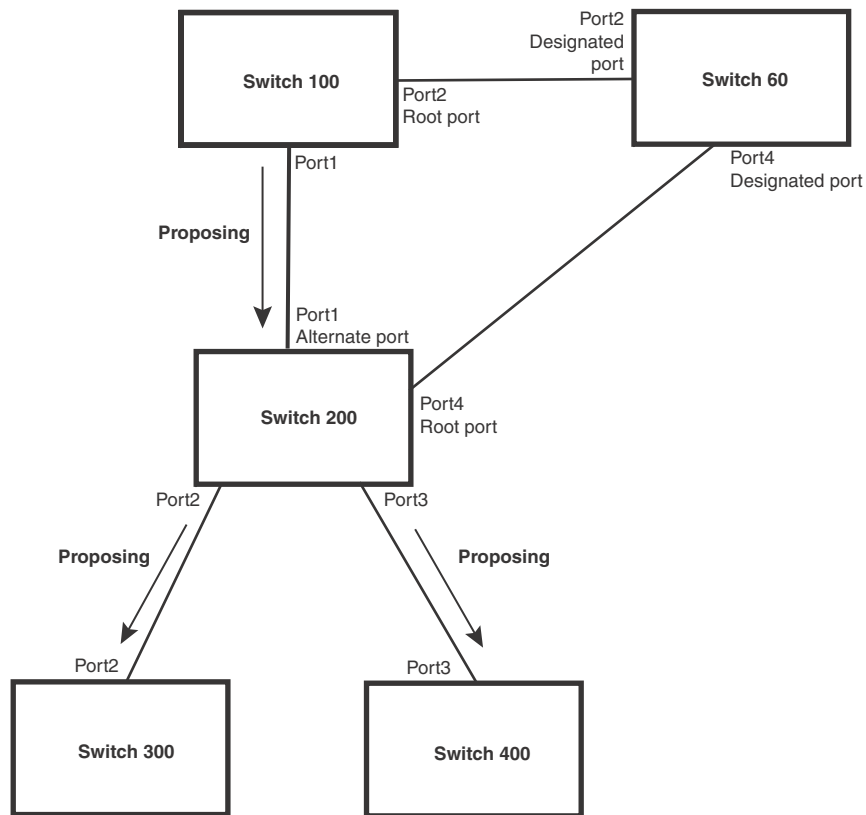

FIGURE 137 Rerooted, synced, and agreed

The old Root port on Switch 200 becomes an Alternate Port (Figure 138). Other ports on that bridge are elected to appropriate roles.

The Designated port on Switch 60 goes into a forwarding state once it receives the RST BPDU with the agreed flag.

FIGURE 138 Handshake completed after election of new root port

Recall that Switch 200 sent the agreed flag to Port4/Switch 60 and not to Port1/Switch 100 (the port that connects Switch 100 to Switch 200). Therefore, Port1/Switch 100 does not go into forwarding state instantly. It waits until two instances of the forward delay timer expires on the port before it goes into forwarding state.

At this point the handshake between the Switch 60 and Switch 200 is complete.

The remaining bridges (Switch 300 and Switch 400) may have to go through the reroot handshake if a new Root port needs to be assigned.

802.1W convergence in a simple topology

The examples in this section illustrate how 802.1W convergence occurs in a simple Layer 2 topology at start-up.

NOTE

The remaining examples assume that the appropriate handshake mechanisms occur as port roles and states change.

Convergence at start up

In [Figure 139](#), two bridges Switch 2 and Switch 3 are powered up. There are point-to-point connections between Port3/Switch 2 and Port3/Switch 3.

FIGURE 139 Convergence between two bridges

At power up, all ports on Switch 2 and Switch 3 assume Designated port roles and are at discarding states before they receive any RST BPDU.

Port3/Switch 2, with a Designated role, transmits an RST BPDU with a proposal flag to Port3/Switch 3. A ports with a Designated role sends the proposal flag in its RST BPDU when they are ready to move to a forwarding state.

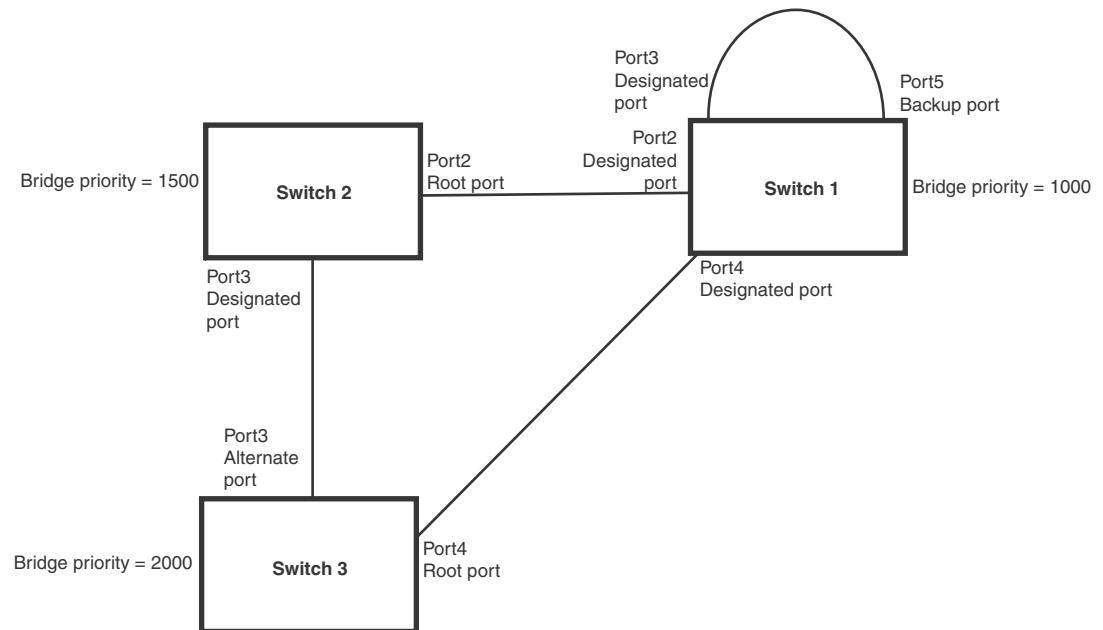

Port3/Switch 3, which starts with a role of Designated port, receives the RST BPDU and finds that it is superior to what it can transmit; therefore, Port3/Switch 3 assumes a new port role, that of a Root port. Port3/Switch 3 transmits an RST BPDU with an agreed flag back to Switch 2 and immediately goes into a forwarding state.

Port3/Switch 2 receives the RST BPDU from Port3/Switch 3 and immediately goes into a forwarding state.

Now 802.1W has fully converged between the two bridges, with Port3/Switch 3 as an operational root port in forwarding state and Port3/Switch 2 as an operational Designated port in forwarding state.

Next, Switch 1 is powered up ([Figure 140](#)).

FIGURE 140 Simple Layer 2 topology

The point-to-point connections between the three bridges are as follows:

- Port2/Switch 1 and Port2/Switch 2
- Port4/Switch 1 and Port4/Switch 3
- Port3/Switch 2 and Port3/Switch 3

Ports 3 and 5 on Switch 1 are physically connected together.

At start up, the ports on Switch 1 assume Designated port roles, which are in discarding state. They begin sending RST BPDUs with proposal flags to move into a forwarding state.

When Port4/Switch 3 receives these RST BPDUs 802.1W algorithm determines that they are better than the RST BPDUs that were previously received on Port3/Switch 3. Port4/Switch 3 is now selected as Root port. This new assignment signals Port3/Switch 3 to begin entering the discarding state and to assume an Alternate port role. As it goes through the transition, Port3/Switch 3 negotiates a new role and state with its peer port, Port3/Switch 2.

Port4/Switch 3 sends an RST BPDU with an agreed flag to Port4/Switch 1. Both ports go into forwarding states.

Port2/Switch 2 receives an RST BPDU. The 802.1W algorithm determines that these RST BPDUs that are superior to any that any port on Switch 2 can transmit; therefore, Port2/Switch 2 assumes the role of a Root port.

The new Root port then signals all ports on the bridge to start synchronization. Since none of the ports are Edge ports, they all enter the discarding state and assume the role of Designated ports. Port3/Switch 2, which previously had a Designated role with a forwarding state, starts the discarding state. They also negotiate port roles and states with their peer ports. Port3/Switch 2 also sends an RST BPU to Port3/Switch 3 with a proposal flag to request permission go into a forwarding state.

STP feature configuration

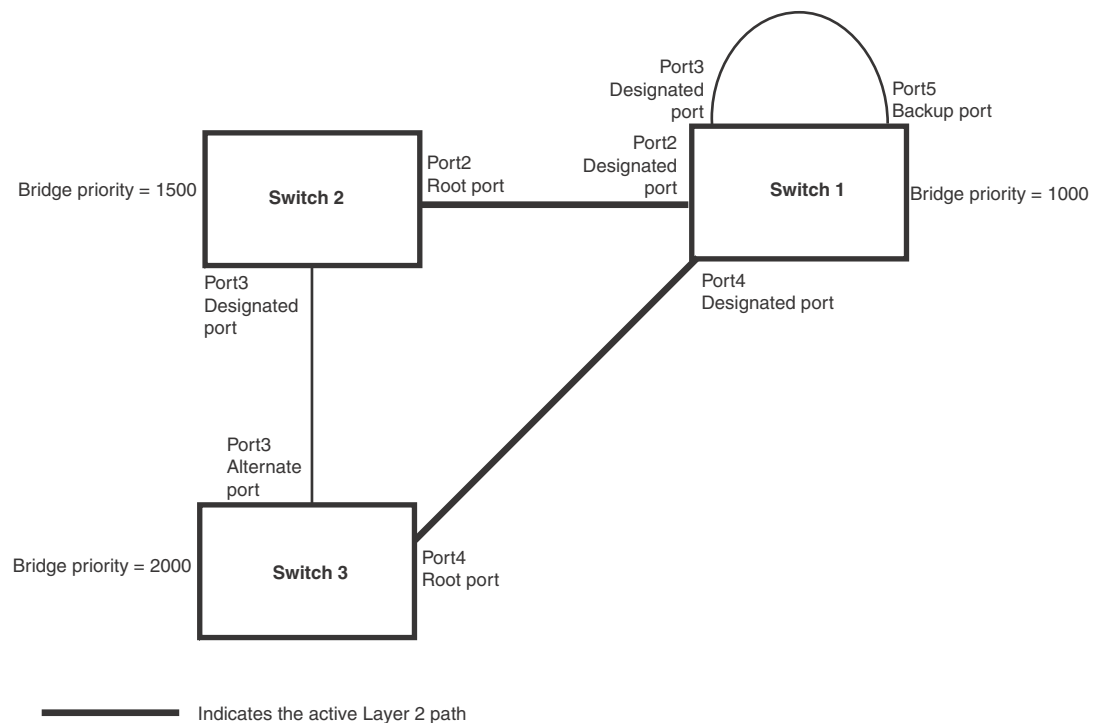

The Port2/Switch 2 bridge also sends an RST BPDU with an agreed flag Port2/Switch 1 that Port2 is the new Root port. Both ports go into forwarding states.

Now, Port3/Switch 3 is currently in a discarding state and is negotiating a port role. It received RST BPDUs from Port3/Switch 2. The 802.1W algorithm determines that the RST BPDUs Port3/Switch 3 received are superior to those it can transmit; however, they are not superior to those that are currently being received by the current Root port (Port4). Therefore, Port3 retains the role of Alternate port.

Ports 3/Switch 1 and Port5/Switch 1 are physically connected. Port5/Switch 1 received RST BPDUs that are superior to those received on Port3/Switch 1; therefore, Port5/Switch 1 is given the Backup port role while Port3 is given the Designated port role. Port3/Switch 1, does not go directly into a forwarding state. It waits until the forward delay time expires twice on that port before it can proceed to the forwarding state.

Once convergence is achieved, the active Layer 2 forwarding path converges as shown in [Figure 141](#).

FIGURE 141 Active Layer 2 path

Convergence after a link failure

Figure 142 illustrates a link failure in the 802.1W topology. In this example, Port2/Switch, which is the port that connects Switch 2 to the root bridge (Switch 1), failed and both Switch 2 and Switch 1 are affected by the topology change.

FIGURE 142 Link failure in the topology

Switch 1 sets its Port2 into a discarding state.

At the same time, Switch 2 assumes the role of a root bridge since its root port failed and it has no operational Alternate port. Port3/Switch 2, which currently has a Designated port role, sends an RST BPDU to Switch 3. The RST BPDU contains a proposal flag and a bridge ID of Switch 2 as its root bridge ID.

When Port3/Switch 3 receives the RST BPDUs, 802.1W algorithm determines that they are inferior to those that the port can transmit. Therefore, Port3/Switch 3 is given a new role, that of a Designated port. Port3/Switch 3 then sends an RST BPDU with a proposal flag to Switch 2, along with the new role information. However, the root bridge ID transmitted in the RST BPDU is still Switch 1.

When Port3/Switch 2 receives the RST BPDU, 802.1W algorithm determines that it is superior to the RST BPDU that it can transmit; therefore, Port3/Switch 2 receives a new role; that of a Root port. Port3/Switch 2 then sends an RST BPDU with an agreed flag to Port3/Switch 3. Port3/Switch 2 goes into a forwarding state.

When Port3/Switch 3 receives the RST BPDU that Port3/Switch 2 sent, Port3/Switch 3 changes into a forwarding state, which then completes the full convergence of the topology.

Convergence at link restoration

When Port2/Switch 2 is restored, both Switch 2 and Switch 1 recognize the change. Port2/Switch 1 starts assuming the role of a Designated port and sends an RST BPDU containing a proposal flag to Port2/Switch 2.

When Port2/Switch 2 receives the RST BPDUs, 802.1W algorithm determines that the RST BPDUs the port received are better than those received on Port3/Switch 3; therefore, Port2/Switch 2 is given the role of a Root port. All the ports on Switch 2 are informed that a new Root port has been assigned which then signals all the ports to synchronize their roles and states. Port3/Switch 2, which was the previous Root port, enters a discarding state and negotiates with other ports on the bridge to establish its new role and state, until it finally assumes the role of a Designated port.

Next, the following happens:

- Port3/Switch 2, the Designated port, sends an RST BPDU, with a proposal flag to Port3/Switch 3.
- Port2/Switch 2 also sends an RST BPDU with an agreed flag to Port2/Switch 1 and then places itself into a forwarding state.

When Port2/Switch 1 receives the RST BPDU with an agreed flag sent by Port2/Switch 2, it puts that port into a forwarding state. The topology is now fully converged.

When Port3/Switch 3 receives the RST BPDU that Port3/Switch 2 sent, 802.1W algorithm determines that these RST BPDUs are superior to those that Port3/Switch 3 can transmit. Therefore, Port3/Switch 3 is given a new role, that of an Alternate port. Port3/Switch 3 immediately enters a discarding state.

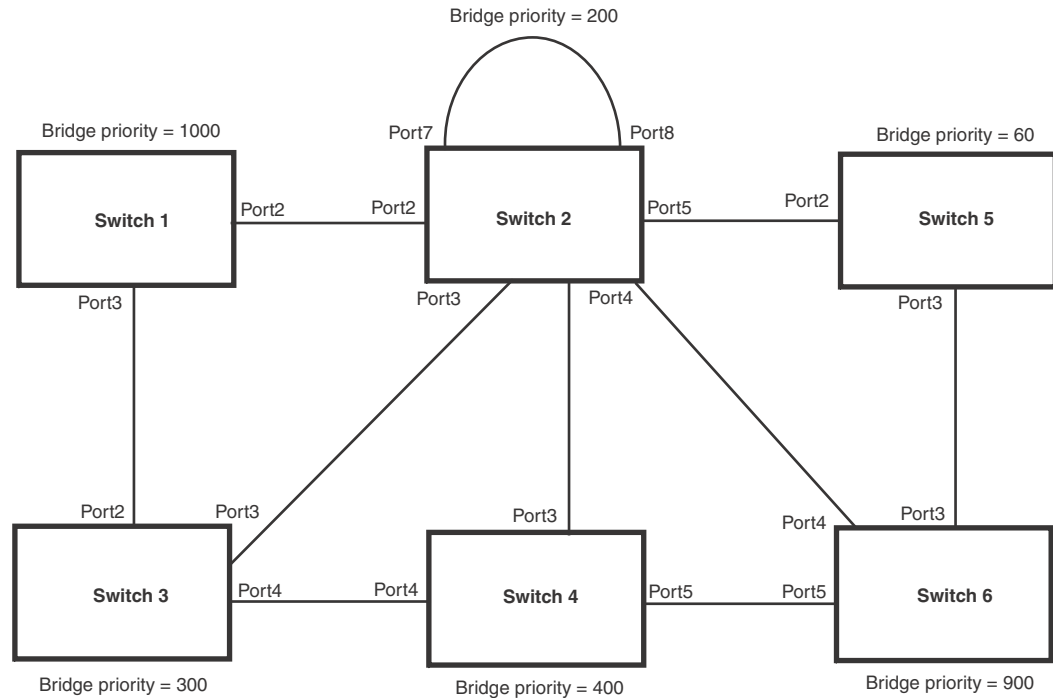

Now Port3/Switch 2 does not go into a forwarding state instantly like the Root port. It waits until the forward delay timer expires twice on that port while it is still in a Designated role, before it can proceed to the forwarding state. The wait, however, does not cause a denial of service, since the essential connectivity in the topology has already been established.

When fully restored, the topology is the same as that shown on [Figure 140](#).

Convergence in a complex 802.1W topology

Figure 143 illustrates a complex 802.1W topology.

FIGURE 143 Complex 802.1W topology

In Figure 143, Switch 5 is selected as the root bridge since it is the bridge with the highest priority. Lines in the figure show the point-to-point connection to the bridges in the topology.

Switch 5 sends an RST BPDU that contains a proposal flag to Port5/Switch 2. When handshakes are completed in Switch 5, Port5/Switch 2 is selected as the Root port on Switch 2. All other ports on Switch 2 are given Designated port role with discarding states.

Port5/Switch 2 then sends an RST BPDU with an agreed flag to Switch 5 to confirm that it is the new Root port and the port enters a forwarding state. Port7 and Port8 are informed of the identity of the new Root port. 802.1W algorithm selects Port7 as the Designated port while Port8 becomes the Backup port.

Port3/Switch 5 sends an RST BPDU to Port3/Switch 6 with a proposal flag. When Port3/Switch 5 receives the RST BPDU, handshake mechanisms select Port3 as the Root port of Switch 6. All other ports are given a Designated port role with discarding states. Port3/Switch 6 then sends an RST BPDU with an agreed flag to Port3/Switch 5 to confirm that it is the Root port. The Root port then goes into a forwarding state.

Now, Port4/Switch 6 receives RST BPDUs that are superior to what it can transmit; therefore, it is given the Alternate port role. The port remains in discarding state.

Port5/Switch 6 receives RST BPDUs that are inferior to what it can transmit. The port is then given a Designated port role.

Next Switch 2 sends RST BPDUs with a proposal flag to Port3/Switch 4. Port3 becomes the Root port for the bridge; all other ports are given a Designated port role with discarding states. Port3/Switch 4 sends an RST BPDU with an agreed flag to Switch 2 to confirm that it is the new Root port. The port then goes into a forwarding state.

Now Port4/Switch 4 receives an RST BPDU that is superior to what it can transmit. The port is then given an Alternate port role, and remains in discarding state.

Likewise, Port5/Switch 4 receives an RST BPDU that is superior to what it can transmit. The port is also given an Alternate port role, and remains in discarding state.

Port2/Switch 2 transmits an RST BPDU with a proposal flag to Port2/Switch 1. Port2/Switch 1 becomes the Root port. All other ports on Switch 1 are given Designated port roles with discarding states.

Port2/Switch 1 sends an RST BPDU with an agreed flag to Port2/Switch 2 and Port2/Switch 1 goes into a forwarding state.

Port3/Switch 1 receives an RST BPDUs that is inferior to what it can transmit; therefore, the port retains its Designated port role and goes into forwarding state only after the forward delay timer expires twice on that port while it is still in a Designated role.

Port3/Switch 2 sends an RST BPDU to Port3/Switch 3 that contains a proposal flag. Port3/Switch 3 becomes the Root port, while all other ports on Switch 3 are given Designated port roles and go into discarding states. Port3/Switch 3 sends an RST BPDU with an agreed flag to Port3/Switch 2 and Port3/Switch 3 goes into a forwarding state.

Now, Port2/Switch 3 receives an RST BPDUs that is superior to what it can transmit so that port is given an Alternate port state.

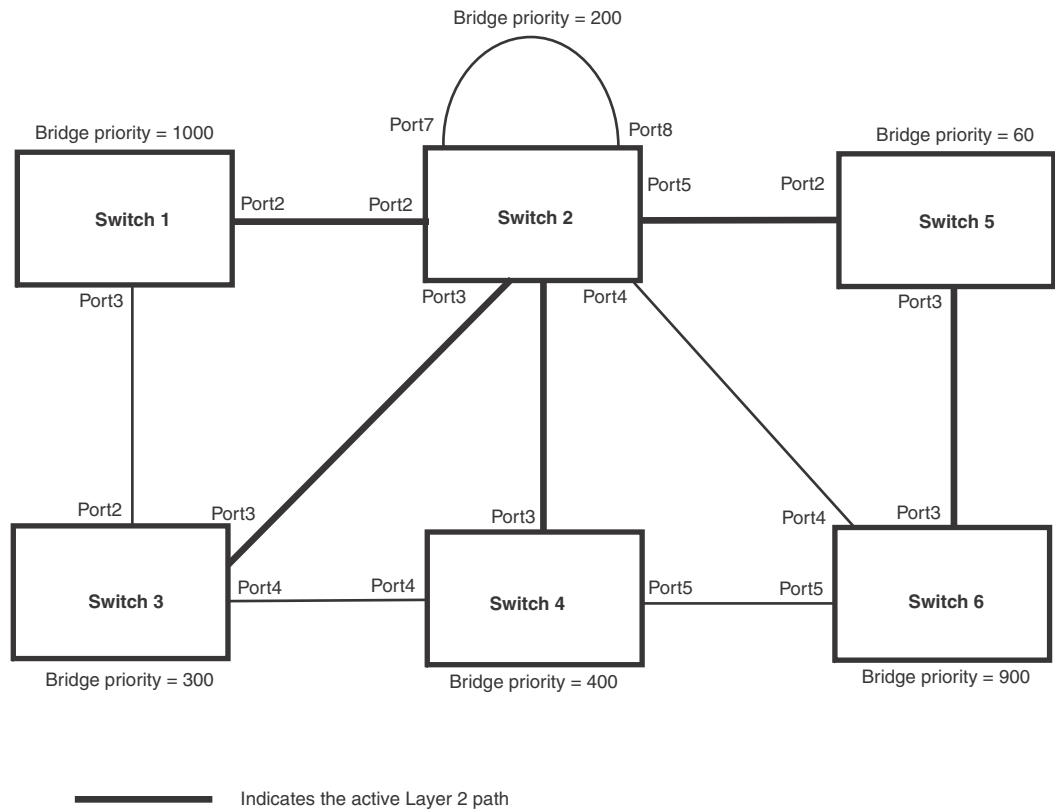

Port4/Switch 3 receives an RST BPDU that is inferior to what it can transmit; therefore, the port retains its Designated port role.

Ports on all the bridges in the topology with Designated port roles that received RST BPDUs with agreed flags go into forwarding states instantly. However, Designated ports that did not receive RST BPDUs with agreed flags must wait until the forward delay timer expires twice on those port. Only then will these port move into forwarding states.

The entire 802.1W topology converges in less than 300 msec and the essential connectivity is established between the designated ports and their connected root ports.

After convergence is complete, [Figure 144](#) shows the active Layer 2 path of the topology in [Figure 143](#).

FIGURE 144 Active Layer 2 path in complex topology

Propagation of topology change

The Topology Change state machine generates and propagates the topology change notification messages on each port. When a Root port or a Designated port goes into a forwarding state, the Topology Change state machine on those ports send a topology change notice (TCN) to all the bridges in the topology to propagate the topology change.

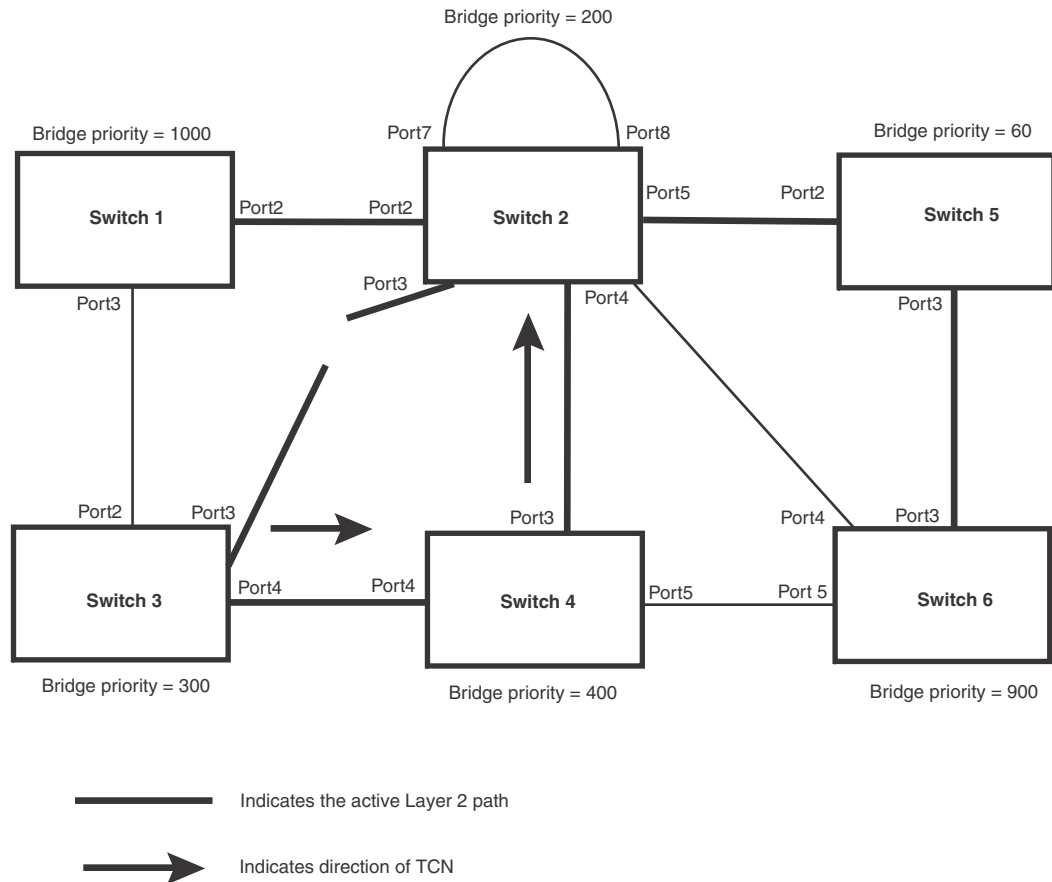

NOTE

Edge ports, Alternate ports, or Backup ports do not need to propagate a topology change.

The TCN is sent in the RST BPDU that a port sends. Ports on other bridges in the topology then acknowledge the topology change once they receive the RST BPDU, and send the TCN to other bridges until all the bridges are informed of the topology change.

For example, Port3/Switch 2 in [Figure 145](#), fails. Port4/Switch 3 becomes the new Root port. Port4/Switch 3 sends an RST BPDU with a TCN to Port4/Switch 4. To propagate the topology change, Port4/Switch 4 then starts a TCN timer on itself, on the bridge Root port, and on other ports on that bridge with a Designated role. Then Port3/Switch 4 sends RST BPDU with the TCN to Port4/Switch 2. (Note the new active Layer 2 path in [Figure 145](#).)

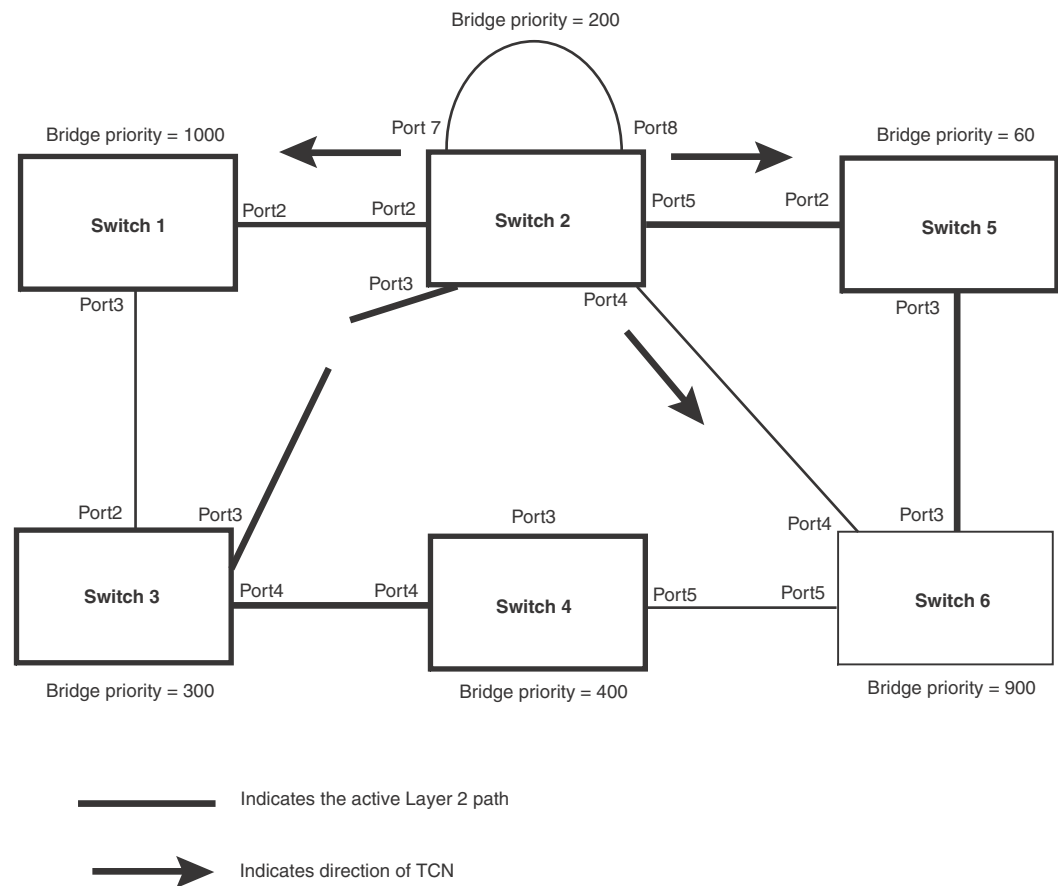

FIGURE 145 Beginning of topology change notice

Switch 2 then starts the TCN timer on the Designated ports and sends RST BPDUs that contain the TCN as follows ([Figure 146](#)):

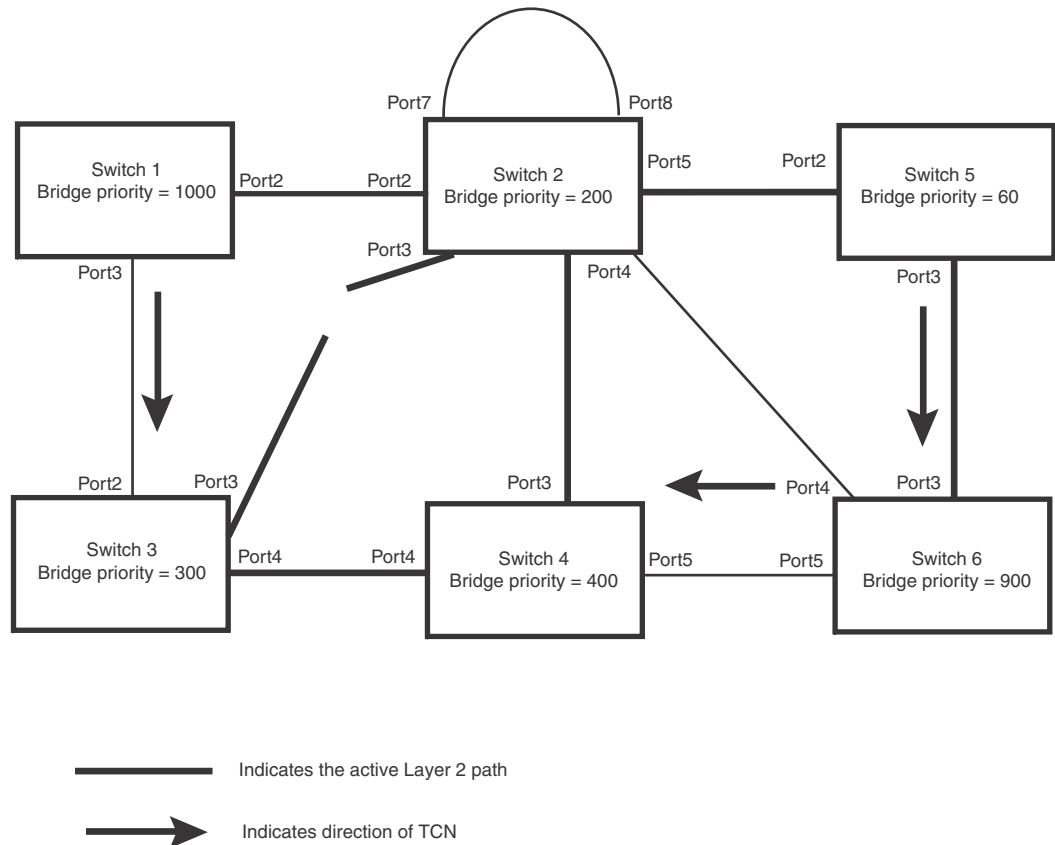

- Port5/Switch 2 sends the TCN to Port2/Switch 5
- Port4/Switch 2 sends the TCN to Port4/Switch 6
- Port2/Switch 2 sends the TCN to Port2/Switch 1

FIGURE 146 Sending TCN to bridges connected to Switch 2

Then Switch 1, Switch 5, and Switch 6 send RST BPDUs that contain the TCN to Switch 3 and Switch 4 to complete the TCN propagation (Figure 147).

FIGURE 147 Completing the TCN propagation

Compatibility of 802.1W with 802.1D

802.1W-enabled bridges are backward compatible with IEEE 802.1D bridges. This compatibility is managed on a per-port basis by the Port Migration state machine. **However, intermixing the two types of bridges in the network topology is not advisable if you want to take advantage of the rapid convergence feature.**

Compatibility with 802.1D means that an 802.1W-enabled port can send BPDUs in the STP or 802.1D format when one of the following events occur:

- The port receives a legacy BPDU. A legacy BPDU is an STP BPDU or a BPDU in an 802.1D format. The port that receives the legacy BPDU automatically configures itself to behave like a legacy port. It sends and receives legacy BPDUs only.
- The entire bridge is configured to operate in an 802.1D mode when an administrator sets the bridge parameter to zero at the CLI, forcing all ports on the bridge to send legacy BPDUs only.

Once a port operates in the 802.1D mode, 802.1D convergence times are used and rapid convergence is not realized.

For example, in [Figure 148](#), Switch 10 and Switch 30 receive legacy BPDUs from Switch 20. Ports on Switch 10 and Switch 30 begin sending BPDUs in STP format to allow them to operate transparently with Switch 20.

FIGURE 148 802.1W bridges with an 802.1D bridge

Once Switch 20 is removed from the LAN, Switch 10 and Switch 30 receive and transmit BPDUs in the STP format to and from each other. This state will continue until the administrator enables the **force-migration-check** command to force the bridge to send RSTP BPDU during a migrate time period. If ports on the bridges continue to hear only STP BPDUs after this migrate time period, those ports will return to sending STP BPDUs. However, when the ports receive RST BPDUs during the migrate time period, the ports begin sending RST BPDUs. The migrate time period is non-configurable. It has a value of three seconds.

NOTE

The IEEE standards state that 802.1W bridges need to interoperate with 802.1D bridges. IEEE standards set the path cost of 802.1W bridges to be between 1 and 200,000,000; whereas path cost of 802.1D bridges are set between 1 and 65,535. In order for the two bridge types to be able to interoperate in the same topology, the administrator needs to configure the bridge path cost appropriately. Path costs for either 802.1W bridges or 802.1D bridges need to be changed; in most cases, path costs for 802.1W bridges need to be changed.

Configuring 802.1W parameters on a Brocade device

The remaining 802.1W sections explain how to configure the 802.1W protocol in a Brocade device.

NOTE

With RSTP running, enabling static trunk on ports that are members of VLAN 4000 will keep the system busy for 20 to 25 seconds.

Brocade devices are shipped from the factory with 802.1W disabled. Use the following methods to enable or disable 802.1W. You can enable or disable 802.1W at the following levels:

- **Port-based VLAN** – Affects all ports within the specified port-based VLAN. When you enable or disable 802.1W within a port-based VLAN, the setting overrides the global setting. Thus, you can enable 802.1W for the ports within a port-based VLAN even when 802.1W is globally disabled, or disable the ports within a port-based VLAN when 802.1W is globally enabled.
- **Individual port** – Affects only the individual port. However, if you change the 802.1W state of the primary port in a trunk group, the change affects all ports in the trunk group.

Enabling or disabling 802.1W in a port-based VLAN

Use the following procedure to disable or enable 802.1W on a device on which you have configured a port-based VLAN. Changing the 802.1W state in a VLAN affects only that VLAN.

To enable 802.1W for all ports in a port-based VLAN, enter commands such as the following.

```
Brocade(config)#vlan 10
Brocade(config-vlan-10)#spanning-tree 802-1w
```

Syntax: [no] spanning-tree 802-1w

Note regarding pasting 802.1W settings into the running configuration

If you paste 802.1W settings into the running configuration, and the pasted configuration includes ports that are already up, the ports will initially operate in STP legacy mode before operating in 802.1W RSTP mode. For example, the following pasted configuration will cause ports e 1 and e 2 to temporarily operate in STP legacy mode, because these ports are already up and running.

```
conf t
vlan 120
tag e 1 to e 2
spanning-tree 802-1w
spanning-tree 802-1w priority 1001
end
```

To avoid this issue, 802.1W commands/settings that are pasted into the configuration should be in the following order.

1. Ports that are not yet connected
2. 802.1W RSTP settings
3. Ports that are already up

Example

```
conf t
vlan 120
untag e 3
spanning-tree 802-1w
spanning-tree 802-1w priority 1001
tag e 1 to 2
end
```

In the above configuration, untagged port e3 is added to VLAN 120 *before* the 802.1W RSTP settings, and ports e1 and e2 are added *after* the 802.1W RSTP settings. When these commands are pasted into the running configuration, the ports will properly operate in 802.1W RSTP mode.

Enabling or disabling 802.1W on a single spanning tree

To enable 802.1W for all ports of a single spanning tree, enter a command such as the following.

```
Brocade(config-vlan-10)#spanning-tree single 802-1w
```

Syntax: [no] spanning-tree single 802-1w

Disabling or enabling 802.1W on an individual port

The **spanning-tree 802-1w** or **spanning-tree single 802-1w** command must be used to initially enable 802.1W on ports. Both commands enable 802.1W on all ports that belong to the VLAN or to the single spanning tree.

Once 802.1W is enabled on a port, it can be disabled on individual ports. 802.1W that have been disabled on individual ports can then be enabled as required.

NOTE

If you change the 802.1W state of the primary port in a trunk group, the change affects all ports in that trunk group.

To disable or enable 802.1W on an individual port, enter commands such as the following.

```
Brocade(config)#interface e 1
Brocade(config-if-e1000-1)#no spanning-tree
```

Syntax: [no] spanning-tree

Changing 802.1W bridge parameters

When you make changes to 802.1W bridge parameters, the changes are applied to individual ports on the bridge. To change 802.1W bridge parameters, use the following methods.

To designate a priority for a bridge, enter a command such as the following.

```
Brocade(config)#spanning-tree 802-1w priority 10
```

The command in this example changes the priority on a device on which you have not configured port-based VLANs. The change applies to the default VLAN. If you have configured a port-based VLAN on the device, you can configure the parameters only at the configuration level for individual VLANs. Enter commands such as the following.

```
Brocade(config)#vlan 20
Brocade(config-vlan-20)#spanning-tree 802-1w priority 0
```

To make this change in the default VLAN, enter the following commands.

```
Brocade(config)#vlan 1
Brocade(config-vlan-1)#spanning-tree 802-1w priority 0
```

Syntax: spanning-tree 802-1w [forward-delay <value>] | [hello-time <value>] | [max-age <time>] | [force-version <value>] | [priority <value>]

The **forward-delay** <value> parameter specifies how long a port waits before it forwards an RST BPDUs after a topology change. This can be a value from 4 – 30 seconds. The default is 15 seconds.

The **hello-time** <value> parameter specifies the interval between two hello packets. This parameter can have a value from 1 – 10 seconds. The default is 2 seconds.

The **max-age** <value> parameter specifies the amount of time the device waits to receive a hello packet before it initiates a topology change. You can specify a value from 6 – 40 seconds. The default is 20 seconds.

The value of **max-age** must be greater than the value of **forward-delay** to ensure that the downstream bridges do not age out faster than the upstream bridges (those bridges that are closer to the root bridge).

The **force-version** <value> parameter forces the bridge to send BPDUs in a specific format. You can specify one of the following values:

- **0** – The STP compatibility mode. Only STP (or legacy) BPDUs will be sent.
- **2** – The default. RST BPDUs will be sent unless a legacy bridge is detected. If a legacy bridge is detected, STP BPDUs will be sent instead.

The default is 2.

The **priority** *<value>* parameter specifies the priority of the bridge. You can enter a value from 0 – 65535. A lower numerical value means the bridge has a higher priority. Thus, the highest priority is 0. The default is 32768.

You can specify some or all of these parameters on the same command line. If you specify more than one parameter, you must specify them in the order shown above, from left to right.

Changing port parameters

The 802.1W port commands can be enabled on individual ports or on multiple ports, such as all ports that belong to a VLAN.

The 802.1W port parameters are preconfigured with default values. If the default parameters meet your network requirements, no other action is required.

You can change the following 802.1W port parameters using the following method.

```
Brocade(config)#vlan 10
Brocade(config-vlan-10)#spanning-tree 802-1w ethernet 5 path-cost 15 priority 64
```

Syntax: **spanning-tree 802-1w ethernet** *<port>* **path-cost** *<value>* | **priority** *<value>* | **[admin-edge-port]** | **[admin-pt2pt-mac]** | **[force-migration-check]**

The **ethernet** *<port>* parameter specifies the interface used. Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

The **path-cost** *<value>* parameter specifies the cost of the port path to the root bridge. 802.1W prefers the path with the lowest cost. You can specify a value from 1 – 20,000,000. [Table 198](#) shows the recommended path cost values from the IEEE standards.

TABLE 198 Recommended path cost values of 802.1W

Link speed	Recommended (Default) 802.1W path cost values	Recommended 802.1W patch cost range
Less than 100 kilobits per second	200,000,000	20,000,000 – 200,000,000
1 Megabit per second	20,000,000	2,000,000 – 200,000,000
10 Megabits per second	2,000,000	200,000 – 200,000,000
100 Megabits per second	200,000	20,000 – 200,000,000
1 Gbps per second	20,000	2,000 – 200,000,000
10 Gbps per second	2,000	200 – 20,000
100 Gbps per second	200	20 – 2,000
1 Terabits per second	20	2 – 200
10 Terabits per second	2	1 – 20

- The **priority** *<value>* parameter specifies the preference that 802.1W gives to this port relative to other ports for forwarding traffic out of the topology. You can specify a value from 0 – 240, in increments of 16. If you enter a value that is not divisible by 16, the software returns an error message. The default value is 128. A higher numerical value means a lower priority; thus, the highest priority is 0.
- Set the **admin-edge-port** to enabled or disabled. If set to enabled, then the port becomes an edge port in the domain.

Set the **admin-pt2pt-mac** to enabled or disabled. If set to enabled, then a port is connected to another port through a point-to-point link. The point-to-point link increases the speed of convergence. This parameter, however, does not auto-detect whether or not the link is a physical point-to-point link.

The **force-migration-check** parameter forces the specified port to send one RST BPDU. If only STP BPDUs are received in response to the sent RST BPDU, then the port will go return to sending STP BPDUs.

Example

Suppose you want to enable 802.1W on a system with no active port-based VLANs and change the hello-time from the default value of 2 to 8 seconds. Additionally, suppose you want to change the path and priority costs for port 5 only. To do so, enter the following commands.

```
Brocade(config)#spanning-tree 802-1w hello-time 8
Brocade(config)#spanning-tree 802-1w ethernet 5 path-cost 15 priority 64
```

Displaying information about 802-1W

To display a summary of 802-1W, use the following command.

```
Brocade#show 802-1w
--- VLAN 1 [ STP Instance owned by VLAN 1 ] -----

Syntax: `show 802-1w [vlan <vlan-id>]`

The **vlan** *<vlan-id>* parameter displays 802.1W information for the specified port-based VLAN.

The **show 802.1w** command shows the information listed in [Table 199](#).

TABLE 199 CLI display of 802.1W summary

Field	Description
VLAN ID	The port-based VLAN that owns the STP instance. VLAN 1 is the default VLAN. If you have not configured port-based VLANs on this device, all 802.1W information is for VLAN 1.
Bridge IEEE 802.1W parameters	
Bridge Identifier	The ID of the bridge.
Bridge Max Age	The configured max age for this bridge. The default is 20.
Bridge Hello	The configured hello time for this bridge. The default is 2.
Bridge FwdDly	The configured forward delay time for this bridge. The default is 15.
Force-Version	The configured force version value. One of the following value is displayed: <ul style="list-style-type: none"> • 0 – The bridge has been forced to operate in an STP compatibility mode. • 2 – The bridge has been forced to operate in an 802.1W mode. (This is the default.)
txHoldCnt	The number of BPDUs that can be transmitted per Hello Interval. The default is 3.
Root Bridge Identifier	ID of the Root bridge that is associated with this bridge
Root Path Cost	The cost to reach the root bridge from this bridge. If the bridge is the root bridge, then this parameter shows a value of zero.
Designated Bridge Identifier	The bridge from where the root information was received. It can be from the root bridge itself, but it could also be from another bridge.
Root Port	The port on which the root information was received. This is the port that is connected to the Designated Bridge.
Max Age	<p>The max age is derived from the Root port. An 802.1W-enabled bridge uses this value, along with the hello and message age parameters to compute the effective age of an RST BPDU.</p> <p>The message age parameter is generated by the Designated port and transmitted in the RST BPDU. RST BPDUs transmitted by a Designated port of the root bridge contains a message value of zero.</p> <p>Effective age is the amount of time the Root port, Alternate port, or Backup port retains the information it received from its peer Designated port. Effective age is reset every time a port receives an RST BPDU from its Designated port. If a Root port does not receive an RST BPDU from its peer Designated port for a duration more than the effective age, the Root port ages out the existing information and recomputes the topology.</p> <p>If the port is operating in 802.1D compatible mode, then max age functionality is the same as in 802.1D (STP).</p>

TABLE 199 CLI display of 802.1W summary (Continued)

Field	Description
Fwd Dly	<p>The number of seconds a non-edge Designated port waits until it can apply any of the following transitions, if the RST BPDU it receives does not have an agreed flag:</p> <ul style="list-style-type: none"> Discarding state to learning state Learning state to forwarding state <p>When a non-edge port receives the RST BPDU it goes into forwarding state within 4 seconds or after two hello timers expire on the port. Fwd Dly is also the number of seconds that a Root port waits for an RST BPDU with a proposal flag before it applies the state transitions listed above.</p> <p>If the port is operating in 802.1D compatible mode, then forward delay functionality is the same as in 802.1D (STP).</p>
Hello	The hello value derived from the Root port. It is the number of seconds between two Hello packets.
Port IEEE 802.1W parameters	
Port Num	The port number shown in a slot#/port# format.
Pri	The configured priority of the port. The default is 128 or 0x80.
Port Path Cost	The configured path cost on a link connected to this port.
P2P Mac	<p>Indicates if the point-to-point-mac parameter is configured to be a point-to-point link:</p> <ul style="list-style-type: none"> T – The link is configured as a point-to-point link. F – The link is not configured as a point-to-point link. This is the default.
Edge port	<p>Indicates if the port is configured as an operational Edge port:</p> <ul style="list-style-type: none"> T – The port is configured as an Edge port. F – The port is not configured as an Edge port. This is the default.
Role	<p>The current role of the port:</p> <ul style="list-style-type: none"> Root Designated Alternate Backup Disabled <p>Refer to “Bridges and bridge port roles” on page 1109 for definitions of the roles.</p>
State	<p>The port current 802.1W state. A port can have one of the following states:</p> <ul style="list-style-type: none"> Forwarding Discarding Learning Disabled <p>Refer to “Bridge port states” on page 1113 and “Edge port and non-edge port states” on page 1114.</p>
Designated Cost	The best root path cost that this port received, including the best root path cost that it can transmit.
Designated Bridge	The ID of the bridge that sent the best RST BPDU that was received on this port.

To display detailed information about 802-1W, enter the **802-1w** command.

```

Syntax: `show 802-1w detail [vlan <vlan-id>]`

The **vlan <vlan-id>** parameter displays 802.1W information for the specified port-based VLAN.

The **show spanning-tree 802.1W** command shows the following information.

TABLE 200 CLI display of show spanning-tree 802.1W

Field	Description
VLAN ID	ID of the VLAN that owns the instance of 802.1W and whether or not it is active.
Bridge ID	ID of the bridge.
forceVersion	the configured version of the bridge: <ul style="list-style-type: none"> • 0 – The bridge has been forced to operate in an STP compatible mode. • 2 – The bridge has been forced to operate in an 802.1W mode.
txHoldCount	The number of BPDUs that can be transmitted per Hello Interval. The default is 3.
Port	ID of the port in slot#/port#format.
Role	The current role of the port: <ul style="list-style-type: none"> • Root • Designated • Alternate • Backup • Disabled Refer to “Bridges and bridge port roles” on page 1109 for definitions of the roles.

TABLE 200 CLI display of show spanning-tree 802.1W (Continued)

Field	Description
State	<p>The port current 802.1W state. A port can have one of the following states:</p> <ul style="list-style-type: none"> • Forwarding • Discarding • Learning • Disabled <p>Refer to “Bridge port states” on page 1113 and “Edge port and non-edge port states” on page 1114.</p>
Path Cost	The configured path cost on a link connected to this port.
Priority	The configured priority of the port. The default is 128 or 0x80.
AdminOperEdge	<p>Indicates if the port is an operational Edge port. Edge ports may either be auto-detected or configured (forced) to be Edge ports using the CLI:</p> <ul style="list-style-type: none"> • T – The port is and Edge port. • F – The port is not an Edge port. This is the default.
AdminP2PMac	<p>Indicates if the point-to-point-mac parameter is configured to be a point-to-point link:</p> <ul style="list-style-type: none"> • T – The link is a point-to-point link • F – The link is not a point-to-point link. This is the default.
DesignatedPriority	<p>Shows the following:</p> <ul style="list-style-type: none"> • Root – Shows the ID of the root bridge for this bridge. • Bridge – Shows the ID of the Designated bridge that is associated with this port.
ActiveTimers	<p>Shows what timers are currently active on this port and the number of seconds they have before they expire:</p> <ul style="list-style-type: none"> • rrWhile – Recent root timer. A non-zero value means that the port has recently been a Root port. • rcvdInfoWhile – Received information timer. Shows the time remaining before the information held by this port expires (ages out). This timer is initialized with the effective age parameter. (Refer to “Max Age” on page 1142.) • rbWhile – Recent backup timer. A non-zero value means that the port has recently been a Backup port. • helloWhen – Hello period timer. The value shown is the amount of time between hello messages. • tcWhile – Topology change timer. The value shown is the interval when topology change notices can be propagated on this port. • fdWhile – Forward delay timer. • mdelayWhile – Migration delay timer. The amount of time that a bridge on the same LAN has to synchronize its migration state with this port before another BPDU type can cause this port to change the BPDU that it transmits.

TABLE 200 CLI display of show spanning-tree 802.1W (Continued)

Field	Description
Machine States	<p>The current states of the various state machines on the port:</p> <ul style="list-style-type: none"> • PIM – State of the Port Information state machine. • PRT – State of the Port Role Transition state machine. • PST – State of the Port State Transition state machine. • TCM – State of the Topology Change state machine. • PPM – State of the Port Protocol Migration. • PTX – State of the Port Transmit state machine. <p>Refer to the section “Port Role Selection state machines” on page 1114 for details on state machines.</p>
Received	<p>Shows the number of BPDU types the port has received:</p> <ul style="list-style-type: none"> • RST BPDU – BPDU in 802.1W format. • Config BPDU – Legacy configuration BPDU (802.1D format). • TCN BPDU – Legacy topology change BPDU (802.1D format).

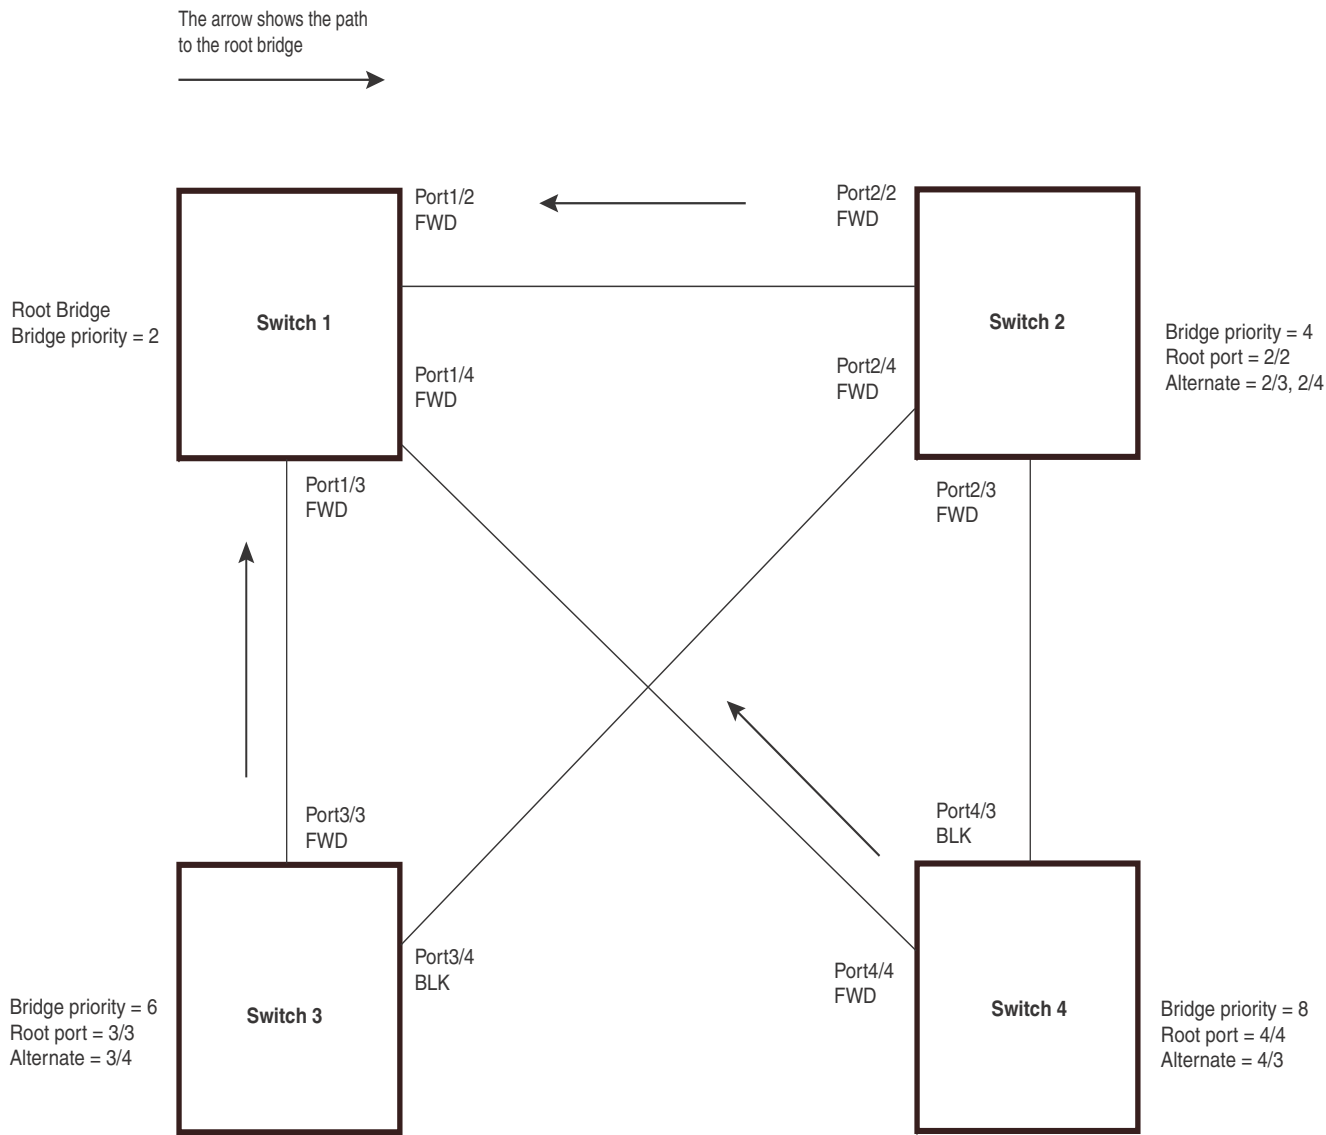

802.1W Draft 3

As an alternative to full 802.1W, you can configure 802.1W Draft 3. 802.1W Draft 3 provides a subset of the RSTP capabilities described in the 802.1W STP specification.

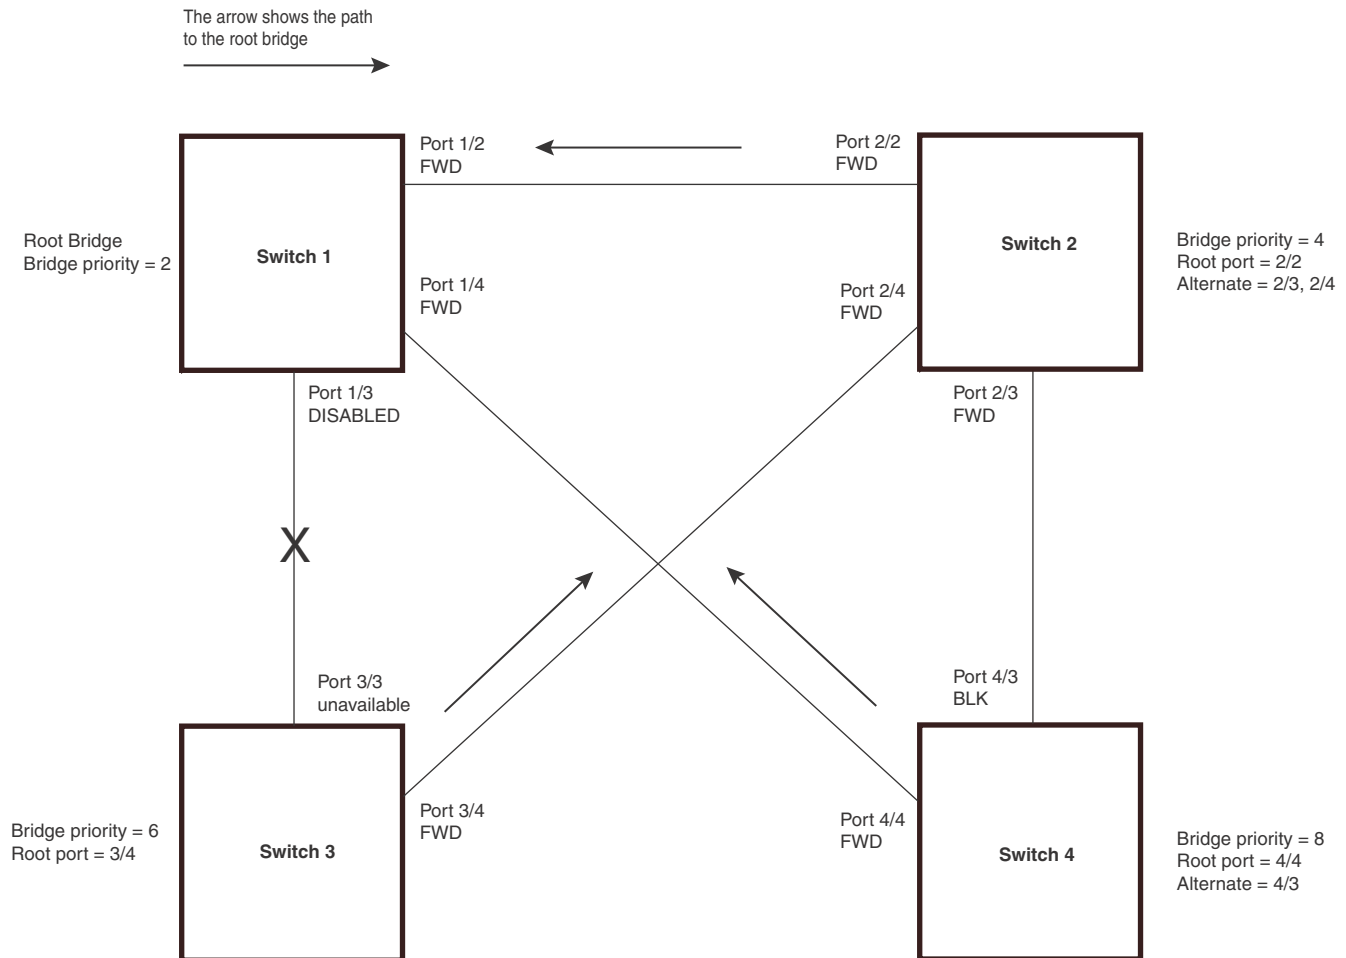

802.1W Draft 3 support is disabled by default. When the feature is enabled, if a root port on a Brocade device that is not the root bridge becomes unavailable, the device can automatically Switch over to an alternate root port, without reconvergence delays. 802.1W Draft 3 does not apply to the root bridge, since all the root bridge ports are always in the forwarding state.

[Figure 149](#) shows an example of an optimal STP topology. In this topology, all the non-root bridges have at least two paths to the root bridge (Switch 1 in this example). One of the paths is through the root port. The other path is a backup and is through the alternate port. While the root port is in the forwarding state, the alternate port is in the blocking state.

FIGURE 149 802.1W Draft 3 RSTP ready for failover

If the root port on a Switch becomes unavailable, 802.1W Draft 3 immediately fails over to the alternate port, as shown in [Figure 150](#).

FIGURE 150 802.1W Draft 3 RSTP failover to alternate root port

In this example, port 3/3 on Switch 3 has become unavailable. In standard STP (802.1D), if the root port becomes unavailable, the Switch must go through the listening and learning stages on the alternate port to reconverge with the spanning tree. Thus, port 3/4 must go through the listening and learning states before entering the forwarding state and thus reconverging with the spanning tree.

802.1W Draft 3 avoids the reconvergence delay by calculating an alternate root port, and immediately failing over to the alternate port if the root port becomes unavailable. The alternate port is in the blocking state as long as the root port is in the forwarding state, but moves immediately to the active state if the root port becomes unavailable. Thus, using 802.1W Draft 3, Switch 3 immediately fails over to port 3/4, without the delays caused by the listening and learning states.

802.1W Draft 3 selects the port with the next-best cost to the root bridge. For example, on Switch 3, port 3/3 has the best cost to the root bridge and thus is selected by STP as the root port. Port 3/4 has the next-best cost to the root bridge, and thus is selected by 802.1W Draft 3 as the alternate path to the root bridge.

Once a failover occurs, the Switch no longer has an alternate root port. If the port that was an alternate port but became the root port fails, standard STP is used to reconverge with the network. You can minimize the reconvergence delay in this case by setting the forwarding delay on the root bridge to a lower value. For example, if the forwarding delay is set to 15 seconds (the default), change the forwarding delay to a value from 3 – 10 seconds.

During failover, 802.1W Draft 3 flushes the MAC addresses learned on the unavailable root port, selects the alternate port as the new root port, and places that port in the forwarding state. If traffic is flowing in both directions on the new root port, addresses are flushed (moved) in the rest of the spanning tree automatically.

Spanning tree reconvergence time

Spanning tree reconvergence using 802.1W Draft 3 can occur within one second.

After the spanning tree reconverges following the topology change, traffic also must reconverge on all the bridges attached to the spanning tree. This is true regardless of whether 802.1W Draft 3 or standard STP is used to reconverge the spanning tree.

Traffic reconvergence happens after the spanning tree reconvergence, and is achieved by flushing the Layer 2 information on the bridges:

- Following 802.1W Draft 3 reconvergence of the spanning tree, traffic reconvergence occurs in the time it takes for the bridge to detect the link changes plus the STP maximum age set on the bridge.
- If standard STP reconvergence occurs instead, traffic reconvergence takes two times the forward delay plus the maximum age.

NOTE

802.1W Draft 3 does not apply when a failed root port comes back up. When this happens, standard STP is used.

802.1W configuration considerations

802.1W Draft 3 is disabled by default. To ensure optimal performance of the feature before you enable it, do the following:

- Configure the bridge priorities so that the root bridge is one that supports 802.1W Draft 3. (Use a Brocade device or third-party device that supports 802.1W Draft 3.)
- Change the forwarding delay on the root bridge to a value lower than the default 15 seconds. Brocade recommends a value from 3 – 10 seconds. The lower forwarding delay helps reduce reconvergence delays in cases where 802.1W Draft 3 is not applicable, such as when a failed root port comes back up.
- Configure the bridge priorities and root port costs so that each device has an active path to the root bridge if its root port becomes unavailable. For example, port 3/4 is connected to port 2/4 on Switch 2, which has the second most favorable bridge priority in the spanning tree.

NOTE

If reconvergence involves changing the state of a root port on a bridge that supports 802.1D STP but not 802.1W Draft 3, then reconvergence still requires the amount of time it takes for the ports on the 802.1D bridge to change state to forwarding (as needed), and receive BPDUs from the root bridge for the new topology.

Enabling 802.1W Draft 3

802.1W Draft 3 is disabled by default. The procedure for enabling the feature differs depending on whether single STP is enabled on the device.

NOTE

STP must be enabled before you can enable 802.1W Draft 3.

Enabling 802.1W Draft 3 when single STP is not enabled

By default, each port-based VLAN on the device has its own spanning tree. To enable 802.1W Draft 3 in a port-based VLAN, enter commands such as the following.

```
Brocade(config)#vlan 10
Brocade(config-vlan-10)#spanning-tree rstp
```

Syntax: [no] spanning-tree rstp

This command enables 802.1W Draft 3. You must enter the command separately in each port-based VLAN in which you want to run 802.1W Draft 3.

NOTE

This command does not also enable STP. To enable STP, first enter the **spanning-tree** command without the **rstp** parameter. After you enable STP, enter the **spanning-tree rstp** command to enable 802.1W Draft 3.

To disable 802.1W Draft 3, enter the following command.

```
Brocade(config-vlan-10)#no spanning-tree rstp
```

Enabling 802.1W Draft 3 when single STP is enabled

To enable 802.1W Draft 3 on a device that is running single STP, enter the following command at the global CONFIG level of the CLI.

```
Brocade(config)#spanning-tree single rstp
```

Syntax: [no] spanning-tree single rstp

This command enables 802.1W Draft 3 on the whole device.

NOTE

This command does not also enable single STP. To enable single STP, first enter the **spanning-tree single** command without the **rstp** parameter. After you enable single STP, enter the **spanning-tree single rstp** command to enable 802.1W Draft 3.

To disable 802.1W Draft 3 on a device that is running single STP, enter the following command.

```
Brocade(config)#no spanning-tree single rstp
```

Single Spanning Tree (SSTP)

By default, each port-based VLAN on a Brocade device runs a separate spanning tree, which you can enable or disable on an individual VLAN basis.

Alternatively, you can configure a Brocade device to run a single spanning tree across all ports and VLANs on the device. The Single STP feature (SSTP) is especially useful for connecting a Brocade device to third-party devices that run a single spanning tree in accordance with the 802.1Q specification.

SSTP uses the same parameters, with the same value ranges and defaults, as the default STP support on Brocade devices. Refer to [“STP parameters and defaults”](#) on page 1088.

SSTP defaults

SSTP is disabled by default. When you enable the feature, all VLANs on which STP is enabled become members of a single spanning tree. All VLANs on which STP is disabled are excluded from the single spanning tree.

To add a VLAN to the single spanning tree, enable STP on that VLAN. To remove a VLAN from the single spanning tree, disable STP on that VLAN.

When you enable SSTP, all the ports that are in port-based VLANs with STP enabled become members of a single spanning tree domain. Thus, the ports share a single BPDU broadcast domain. The Brocade device places all the ports in a non-configurable VLAN, 4094, to implement the SSTP domain. However, this VLAN does not affect port membership in the port-based VLANs you have configured. Other broadcast traffic is still contained within the individual port-based VLANs. Therefore, you can use SSTP while still using your existing VLAN configurations without changing your network. In addition, SSTP does not affect 802.1Q tagging. Tagged and untagged ports alike can be members of the single spanning tree domain.

NOTE

When SSTP is enabled, the BPDUs on tagged ports go out untagged.

If you disable SSTP, all VLANs that were members of the single spanning tree run MSTP instead. In MSTP, each VLAN has its own spanning tree. VLANs that were not members of the single spanning tree were not enabled for STP. Therefore, STP remains disabled on those VLANs.

Enabling SSTP

To enable SSTP, use one of the following methods.

NOTE

If the device has only one port-based VLAN (the default VLAN), then the device is already running a single instance of STP. In this case, you do not need to enable SSTP. You need to enable SSTP only if the device contains more than one port-based VLAN and you want all the ports to be in the same STP broadcast domain.

To configure the Brocade device to run a single spanning tree, enter the following command at the global CONFIG level.

```
Brocade(config)#spanning-tree single
```

NOTE

If the device has only one port-based VLAN, the CLI command for enabling SSTP is not listed in the CLI. The command is listed only if you have configured a port-based VLAN.

To change a global STP parameter, enter a command such as the following at the global CONFIG level.

```
Brocade(config)# spanning-tree single priority 2
```

This command changes the STP priority for all ports to 2.

To change an STP parameter for a specific port, enter commands such as the following.

```
Brocade(config) spanning-tree single ethernet 1 priority 10
```

The commands shown above override the global setting for STP priority and set the priority to 10 for port 1/1.

Here is the syntax for the global STP parameters.

Syntax: [no] spanning-tree single [forward-delay <value>] [hello-time <value>] | [maximum-age <time>] | [priority <value>]

Here is the syntax for the STP port parameters.

Syntax: [no] spanning-tree single [ethernet <port> path-cost <value> | priority <value>]

NOTE

Both commands listed above are entered at the global CONFIG level.

Displaying SSTP information

To verify that SSTP is in effect, enter the following commands at any level of the CLI.

```
Brocade#show span
```

Syntax: show span [vlan <vlan-id>] | [pvst-mode] | [<num>] | [detail [vlan <vlan-id> [ethernet <port>] | <num>]]

The **vlan** <vlan-id> parameter displays STP information for the specified port-based VLAN.

The **pvst-mode** parameter displays STP information for the device Per VLAN Spanning Tree (PVST+) compatibility configuration. Refer to “[PVST/PVST+ compatibility](#)” on page 1157.

Specify the **port** variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

The <num> parameter displays only the entries after the number you specify. For example, on a device with three port-based VLANs, if you enter 1, then information for the second and third VLANs is displayed, but information for the first VLAN is not displayed. Information is displayed according to VLAN number, in ascending order. The entry number is not the same as the VLAN number. For example, if you have port-based VLANs 1, 10, and 2024, then the command output has three STP entries. To display information for VLANs 10 and 2024 only, enter **show span 1**.

The **detail** parameter and its additional optional parameters display detailed information for individual ports. Refer to [“Displaying detailed STP information for each interface”](#) on page 1099.

STP per VLAN group

STP per VLAN group is an STP enhancement that provides scalability while overcoming the limitations of the following scalability alternatives:

- **Standard STP** – You can configure up to 254 instances of standard STP on a Brocade device. It is possible to need more instances of STP than this in large configurations. Using STP per VLAN group, you can aggregate STP instances.
- **Single STP** – Single STP allows all the VLANs to run STP, but each VLAN runs the same instance of STP, resulting in numerous blocked ports that do not pass any Layer 2 traffic. STP per VLAN group uses all available links by load balancing traffic for different instances of STP on different ports. A port that blocks traffic for one spanning tree forwards traffic for another spanning tree.

STP per VLAN group allows you to group VLANs and apply the same STP parameter settings to all the VLANs in the group. [Figure 151](#) shows an example of a STP per VLAN group implementation.

FIGURE 151 STP per VLAN group example

A master VLAN contains one or more member VLANs. Each of the member VLANs in the STP Group runs the same instance of STP and uses the STP parameters configured for the master VLAN. In this example, the FastIron switch is configured with VLANs 3, 4, 13, and 14. VLANs 3 and 4 are grouped in master VLAN 2, which is in STP group 1. VLANs 13 and 14 are grouped in master VLAN 12, which is in STP group 2. The VLANs in STP group 1 all share the same spanning tree. The VLANs in STP group 2 share a different spanning tree.

All the ports are tagged. The ports must be tagged so that they can be in both a member VLAN and the member's master VLAN. For example, ports 1/1 – 1/4 are in member VLAN 3 and also in master VLAN 2 (since master VLAN 2 contains member VLAN 3).

STP load balancing

Notice that the STP groups each have different STP priorities. In configurations that use the STP groups on multiple devices, you can use the STP priorities to load balance the STP traffic. By setting the STP priorities for the same STP group to different values on each device, you can cause each of the devices to be the root bridge for a different STP group. This type of configuration distributes the traffic evenly across the devices and also ensures that ports that are blocked in one STP group spanning tree are used by another STP group spanning tree for forwarding. Refer to [“Configuration example for STP load sharing”](#) on page 1155 for an example using STP load sharing.

Configuring STP per VLAN group

To configure STP per VLAN group, perform the following tasks:

1. Configure the member VLANs.
2. Optionally, configure master VLANs to contain the member VLANs. This is useful when you have a lot of member VLANs and you do not want to individually configure STP on each one. Each of the member VLANs in the STP group uses the STP settings of the master VLAN.
3. Configure the STP groups. Each STP group runs a separate instance of STP.

The following CLI commands implement the STP per VLAN group configuration shown in [Figure 151](#). The following commands configure the member VLANs (3, 4, 13, and 14) and the master VLANs (2 and 12). Notice that changes to STP parameters are made in the master VLANs only, not in the member VLANs.

```
Brocade(config)#vlan 2
Brocade(config-vlan-2)#spanning-tree priority 1
Brocade(config-vlan-2)#tagged ethernet 1/1 to 1/4
Brocade(config-vlan-2)#vlan 3
Brocade(config-vlan-3)#tagged ethernet 1/1 to 1/4
Brocade(config-vlan-3)#vlan 4
Brocade(config-vlan-4)#tagged ethernet 1/1 to 1/4
Brocade(config-vlan-4)#vlan 12
Brocade(config-vlan-12)#spanning-tree priority 2
Brocade(config-vlan-12)#tagged ethernet 1/1 to 1/4
Brocade(config-vlan-12)#vlan 13
Brocade(config-vlan-13)#tagged ethernet 1/1 to 1/4
Brocade(config-vlan-13)#vlan 14
Brocade(config-vlan-14)#tagged ethernet 1/1 to 1/4
Brocade(config-vlan-14)#exit
```

The following commands configure the STP groups.

```
Brocade(config)#stp-group 1
Brocade(config-stp-group-1)#master-vlan 2
Brocade(config-stp-group-1)#member-vlan 3 to 4
Brocade(config-stp-group-1)#exit
Brocade(config)#stp-group 2
Brocade(config-stp-group-2)#master-vlan 12
Brocade(config-stp-group-2)#member-vlan 13 to 14
```

Syntax: [no] stp-group <num>

This command changes the CLI to the STP group configuration level. The following commands are valid at this level. The <num> parameter specifies the STP group ID and can be from 1 – 32.

Syntax: `[no] master-vlan <num>`

This command adds a master VLAN to the STP group. The master VLAN contains the STP settings for all the VLANs in the STP per VLAN group. The `<num>` parameter specifies the VLAN ID. An STP group can contain one master VLAN.

If you delete the master VLAN from an STP group, the software automatically assigns the first member VLAN in the group to be the new master VLAN for the group.

Syntax: `[no] member-vlan <num> [to <num>]`

This command adds additional VLANs to the STP group. These VLANs also inherit the STP settings of the master VLAN in the group.

Syntax: `[no] member-group <num>`

This command adds a member group (a VLAN group) to the STP group. All the VLANs in the member group inherit the STP settings of the master VLAN in the group. The `<num>` parameter specifies the VLAN group ID.

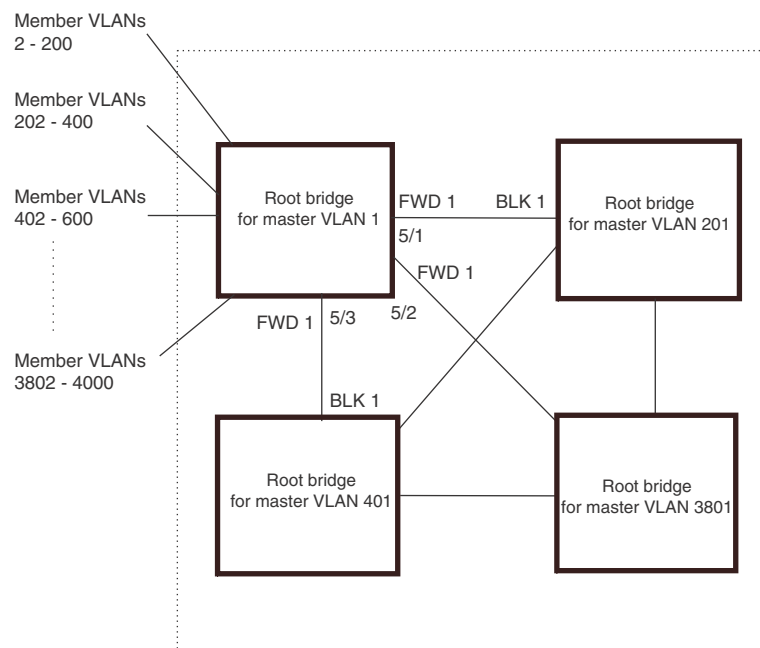

NOTE

This command is optional and is not used in the example above. For an example of this command, refer to [“Configuration example for STP load sharing”](#).

Configuration example for STP load sharing

Figure 152 shows another example of a STP per VLAN group implementation.

FIGURE 152 More complex STP per VLAN group example

In this example, each of the devices in the core is configured with a common set of master VLANs, each of which contains one or more member VLANs. Each of the member VLANs in an STP group runs the same instance of STP and uses the STP parameters configured for the master VLAN.

The STP group ID identifies the STP instance. All VLANs within an STP group run the same instance of STP. The master VLAN specifies the bridge STP parameters for the STP group, including the bridge priority. In this example, each of the devices in the core is configured to be the default root bridge for a different master VLAN. This configuration ensures that each link can be used for forwarding some traffic. For example, all the ports on the root bridge for master VLAN 1 are configured to forward BPDUs for master VLAN spanning tree. Ports on the other devices block or forward VLAN 1 traffic based on STP convergence. All the ports on the root bridge for VLAN 2 forward VLAN 2 traffic, and so on.

All the ports are tagged. The ports must be tagged so that they can be in both a member VLAN and the member's master VLAN. For example, port 1/1 – and ports 5/1, 5/2, and 5/3 are in member VLAN 2 and master VLAN 1 (since master VLAN 1 contains member VLAN 2).

Here are the commands for configuring the root bridge for master VLAN 1 in figure [Figure 151](#) for STP per VLAN group. The first group of commands configures the master VLANs. Notice that the STP priority is set to a different value for each VLAN. In addition, the same VLAN has a different STP priority on each device. This provides load balancing by making each of the devices a root bridge for a different spanning tree.

```
Brocade(config)#vlan 1
Brocade(config-vlan-1)#spanning-tree priority 1
Brocade(config-vlan-1)#tag ethernet 1/1 ethernet 5/1 to 5/3
Brocade(config-vlan-1)#vlan 201
Brocade(config-vlan-201)#spanning-tree priority 2
Brocade(config-vlan-201)#tag ethernet 1/2 ethernet 5/1 to 5/3
Brocade(config-vlan-201)#vlan 401
Brocade(config-vlan-401)#spanning-tree priority 3
Brocade(config-vlan-401)#tag ethernet 1/3 ethernet 5/1 to 5/3
...
Brocade(config-vlan-3601)#vlan 3801
Brocade(config-vlan-3801)#spanning-tree priority 20
Brocade(config-vlan-3801)#tag ethernet 1/20 ethernet 5/1 to 5/3
Brocade(config-vlan-3801)#exit
```

The next group of commands configures VLAN groups for the member VLANs. Notice that the VLAN groups do not contain the VLAN numbers assigned to the master VLANs. Also notice that no STP parameters are configured for the groups of member VLANs. Each group of member VLANs will inherit its STP settings from its master VLAN.

Set the bridge priority for each master VLAN to the highest priority (1) on one of the devices in the STP per VLAN group configuration. By setting the bridge priority to the highest priority, you make the device the default root bridge for the spanning tree. To ensure STP load balancing, make each of the devices the default root bridge for a different master VLAN.

```
Brocade(config)#vlan-group 1 vlan 2 to 200
Brocade(config-vlan-group-1)#tag ethernet 1/1 ethernet 5/1 to 5/3
Brocade(config-vlan-group-1)#vlan-group 2 vlan 202 to 400
Brocade(config-vlan-group-2)#tag ethernet 1/2 ethernet 5/1 to 5/3
Brocade(config-vlan-group-2)#vlan-group 3 vlan 402 to 600
Brocade(config-vlan-group-2)#tag ethernet 1/3 ethernet 5/1 to 5/3
...
Brocade(config-vlan-group-19)#vlan-group 20 vlan 3082 to 3282
Brocade(config-vlan-group-20)#tag ethernet 1/20 ethernet 5/1 to 5/3
Brocade(config-vlan-group-20)#exit
```

The following group of commands configures the STP groups. Each STP group in this configuration contains one master VLAN, which contains a VLAN group. This example shows that an STP group also can contain additional VLANs (VLANs not configured in a VLAN group).

```

Brocade(config)#stp-group 1
Brocade(config-stp-group-1)#master-vlan 1
Brocade(config-stp-group-1)#member-group 1
Brocade(config-stp-group-1)#member-vlan 4001 4004 to 4010
Brocade(config-stp-group-1)#stp-group 2
Brocade(config-stp-group-2)#master-vlan 201
Brocade(config-stp-group-2)#member-group 2
Brocade(config-stp-group-2)#member-vlan 4002 4003 4011 to 4015
Brocade(config-stp-group-2)#stp-group 3
Brocade(config-stp-group-3)#master-vlan 401
Brocade(config-stp-group-3)#member-group 3
...
Brocade(config-stp-group-19)#stp-group 20
Brocade(config-stp-group-20)#master-vlan 3081
Brocade(config-stp-group-20)#member-group 20

```

PVST/PVST+ compatibility

The FastIron family of switches support Cisco's Per VLAN Spanning Tree plus (PVST+), by allowing the device to run multiple spanning trees (MSTP) while also interoperating with IEEE 802.1Q devices¹.

NOTE

Brocade ports automatically detect PVST+ BPDUs and enable support for the BPDUs once detected. You do not need to perform any configuration steps to enable PVST+ support. However, to support the IEEE 802.1Q BPDUs, you might need to enable dual-mode support.

Support for Cisco's Per VLAN Spanning Tree plus (PVST+), allows a Brocade device to run multiple spanning trees (MSTP) while also interoperating with IEEE 802.1Q devices. Brocade ports automatically detect PVST+ BPDUs and enable support for the BPDUs once detected. The enhancement allows a port that is in PVST+ compatibility mode due to auto-detection to revert to the default MSTP mode when one of the following events occurs:

- The link is disconnected or broken
- The link is administratively disabled
- The link is disabled by interaction with the link-keepalive protocol

This enhancement allows a port that was originally interoperating with PVST+ to revert to MSTP when connected to a Brocade device.

Overview of PVST and PVST+

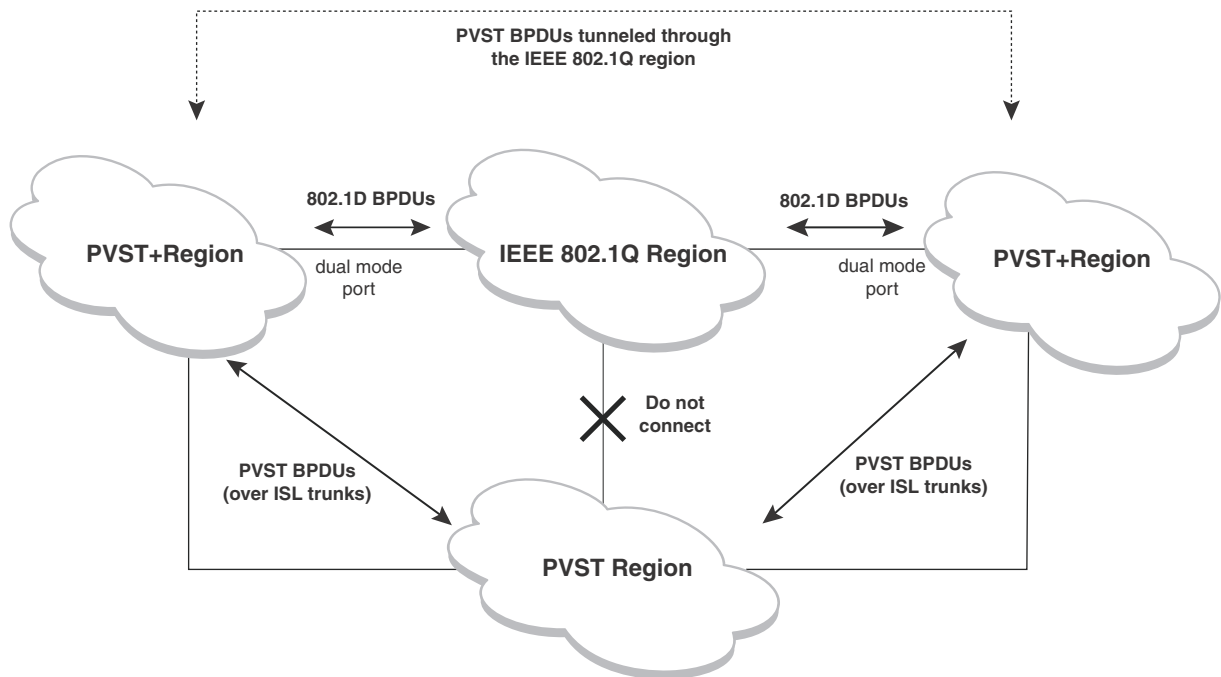

Per VLAN Spanning Tree (PVST) is a Cisco proprietary protocol that allows a Cisco device to have multiple spanning trees. The Cisco device can interoperate with spanning trees on other PVST devices but cannot interoperate with IEEE 802.1Q devices. An IEEE 802.1Q device has all its ports running a single spanning tree. **PVST+** is an extension of PVST that allows a Cisco device to also interoperate with devices that are running a single spanning tree (IEEE 802.1Q).

Enhanced PVST+ support allows a Brocade device to interoperate with PVST spanning trees and the IEEE 802.1Q spanning tree at the same time.

1. Cisco user documentation for PVST/PVST+ refers to the IEEE 802.1Q spanning tree as the **Common Spanning Tree (CST)**.

IEEE 802.1Q and PVST regions cannot interoperate directly but can interoperate indirectly through PVST+ regions. PVST BPDUs are tunneled through 802.1Q regions, while PVST BPDUs for VLAN 1 (the IEEE 802.1Q VLAN) are processed by PVST+ regions. [Figure 153](#) shows the interaction of IEEE 802.1Q, PVST, and PVST+ regions.

FIGURE 153 Interaction of IEEE 802.1Q, PVST, and PVST+ regions

VLAN tags and dual mode

The **dual-mode** feature enables a port to send and receive both tagged and untagged frames. When the dual-mode feature is enabled on a port, the port is an untagged member of one of its VLANs and is at the same time a tagged member of all its other VLANs. The untagged frames are supported on the port **Port Native VLAN**.

The dual-mode feature must be enabled on a Brocade port in order to interoperate with another vendor device. Some vendors use VLAN 1 by default to support the IEEE 802.1Q-based standard spanning tree protocols, such as 802.1d and 802.1w for sending untagged frames on VLAN 1. On Brocade switches, by default, the **Port Native VLAN** is the same as the **Default VLAN**, which is VLAN 1. Thus, to support IEEE 802.1Q in a typical configuration, a port must be able to send and receive untagged frames for VLAN 1 and tagged frames for the other VLANs, and interoperate with other vendor devices using VLAN 1.

If you want to use tagged frames on VLAN 1, you can change the default VLAN ID to an ID other than 1. You also can specify the VLAN on which you want the port to send and receive untagged frames (the Port Native VLAN). The Port Native VLAN ID does not need to be the same as the default VLAN. Make sure that the untagged (native) VLAN is also changed on the interoperating vendor side to match that on the Brocade side.

To support the IEEE 802.1Q with non-standard proprietary protocols such as PVST and PVST+, a port must always send and receive untagged frames on VLAN 1 on both sides. In this case, enable the dual-mode 1 feature to allow untagged BPDUs on VLAN 1 and use Native VLAN 1 on the interoperating vendor side. You should not use VLAN 1 for tagged frames in this case.

Configuring PVST+ support

PVST+ support is automatically enabled when the port receives a PVST BPDU. You can manually enable the support at any time or disable the support if desired.

If you want a tagged port to also support IEEE 802.1Q BPDUs, you need to enable the dual-mode feature on the port. The dual-mode feature is disabled by default and must be enabled manually.

A port that is in PVST+ compatibility mode due to auto-detection reverts to the default MSTP mode when one of the following events occurs:

- The link is disconnected or broken
- The link is administratively disabled
- The link is disabled by interaction with the link-keepalive protocol

This allows a port that was originally interoperating with PVST+ to revert to MSTP when connected to a Brocade device.

Enabling PVST+ support manually

To immediately enable PVST+ support on a port, enter commands such as the following.

```
Brocade(config)#interface ethernet 1/1
Brocade(config-if-1/1)#pvst-mode
```

Syntax: [no] pvst-mode

NOTE

If you disable PVST+ support, the software still automatically enables PVST+ support if the port receives a BPDU with PVST+ format.

NOTE

If 802.1W and pvst-mode (either by auto-detection or by explicit configuration) are enabled on a tagged VLAN port, 802.1W will treat the PVST BPDUs as legacy 802.1D BPDUs.

Enabling dual-mode support

To enable the dual-mode feature on a port, enter the following command at the interface configuration level for the port.

```
Brocade(config-if-1/1)#dual-mode
```

Syntax: [no] dual-mode [<vlan-id>]

The <vlan-id> specifies the port Port Native VLAN. This is the VLAN on which the port will support untagged frames. By default, the Port Native VLAN is the same as the default VLAN (which is VLAN 1 by default).

For more information about the dual-mode feature, refer to [“Dual-mode VLAN ports”](#) on page 818.

Displaying PVST+ support information

To display PVST+ information for ports on a Brocade device, enter the following command at any level of the CLI.

```
Brocade#show span pvst-mode
PVST+ Enabled on:
Port      Method
1/1       Set by configuration
1/2       Set by configuration
2/10      Set by auto-detect
3/12      Set by configuration
4/24      Set by auto-detect
```

Syntax: show span pvst-mode

This command displays the following information.

TABLE 201 CLI display of PVST+ information

Field	Description
Port	The Brocade port number. NOTE: The command lists information only for the ports on which PVST+ support is enabled.
Method	The method by which PVST+ support was enabled on the port. The method can be one of the following: <ul style="list-style-type: none"> Set by configuration – You enabled the support. Set by auto-detect – The support was enabled automatically when the port received a PVST+ BPDU.

PVST+ configuration examples

The following examples show configuration examples for two common configurations:

- Untagged IEEE 802.1Q BPDUs on VLAN 1 and tagged PVST+ BPDUs on other VLANs
- Tagged IEEE 802.1Q BPDUs on VLAN 1 and untagged BPDUs on another VLAN

Tagged port using default VLAN 1 as its port native VLAN

Figure 154 shows an example of a PVST+ configuration that uses VLAN 1 as the untagged default VLAN and VLANs 2, 3, and 4 as tagged VLANs.

FIGURE 154 Default VLAN 1 for untagged BPDU

To implement this configuration, enter the following commands.

Commands on the Brocade Device

```
Brocade(config)#vlan-group 1 vlan 2 to 4
Brocade(config-vlan-group-1)#tagged ethernet 1/1
Brocade(config-vlan-group-1)#exit
Brocade(config)#interface ethernet 1/1
Brocade(config-if-1/1)#dual-mode
Brocade(config-if-1/1)#pvst-mode
```

These commands configure a VLAN group containing VLANs 2, 3, and 4, add port 1/1 as a tagged port to the VLANs, and enable the dual-mode feature and PVST+ support on the port. The dual-mode feature allows the port to send and receive untagged frames for the default VLAN (VLAN 1 in this case) in addition to tagged frames for VLANs 2, 3, and 4. Enabling the PVST+ support ensures that the port is ready to send and receive PVST+ BPDUs. If you do not manually enable PVST+ support, the support is not enabled until the port receives a PVST+ BPDU.

The configuration leaves the default VLAN and the port Port Native VLAN unchanged. The default VLAN is 1 and the port Port Native VLAN also is 1. The dual-mode feature supports untagged frames on the default VLAN only. Thus, port 1/1 can send and receive untagged BPDUs for VLAN 1 and can send and receive tagged BPDUs for the other VLANs.

Port 1/1 will process BPDUs as follows:

- Process IEEE 802.1Q BPDUs for VLAN 1.
- Process tagged PVST BPDUs for VLANs 2, 3, and 4.
- Drop untagged PVST BPDUs for VLAN 1.

Untagged port using VLAN 2 as port native VLAN

Figure 155 shows an example in which a port Port Native VLAN is not VLAN 1. In this case, VLAN 1 uses tagged frames and VLAN 2 uses untagged frames.

FIGURE 155 Port Native VLAN 2 for Untagged BPDUs

To implement this configuration, enter the following commands.

Commands on the Brocade Device

```
Brocade(config)#default-vlan-id 4000
Brocade(config)#vlan 1
Brocade(config-vlan-1)#tagged ethernet 1/1
Brocade(config-vlan-1)#exit
Brocade(config)#vlan 2
Brocade(config-vlan-2)#tagged ethernet 1/1
Brocade(config-vlan-2)#exit
```

```

Brocade(config)#interface ethernet 1/1
Brocade(config-if-1/1)#dual-mode 2
Brocade(config-if-1/1)#pvst-mode
Brocade(config-if-1/1)#exit

```

These commands change the default VLAN ID, configure port 1/1 as a tagged member of VLANs 1 and 2, and enable the dual-mode feature and PVST+ support on port 1/1. Since VLAN 1 is tagged in this configuration, the default VLAN ID must be changed from VLAN 1 to another VLAN ID. Changing the default VLAN ID from 1 allows the port to process tagged frames for VLAN 1. VLAN 2 is specified with the **dual-mode** command, which makes VLAN 2 the port Port Native VLAN. As a result, the port processes untagged frames and untagged PVST BPDUs on VLAN 2.

NOTE

Although VLAN 2 becomes the port untagged VLAN, the CLI still requires that you add the port to the VLAN as a tagged port, since the port is a member of more than one VLAN.

Port 1/1 will process BPDUs as follows:

- Process IEEE 802.1Q BPDUs for VLAN 1.
- Process untagged PVST BPDUs for VLAN 2.
- Drop tagged PVST BPDUs for VLAN 1.

Note that when VLAN 1 is not the default VLAN, the ports must have the dual-mode feature enabled in order to process IEEE 802.1Q BPDUs.

For example, the following configuration is incorrect.

```

Brocade(config)#default-vlan-id 1000
Brocade(config)#vlan 1
Brocade(config-vlan-1)#tagged ethernet 1/1 to 1/2
Brocade(config-vlan-1)#exit
Brocade(config)#interface ethernet 1/1
Brocade(config-if-1/1)#pvst-mode
Brocade(config-if-1/1)#exit
Brocade(config)#interface ethernet 1/2
Brocade(config-if-1/2)#pvst-mode
Brocade(config-if-1/2)#exit

```

In the configuration above, all PVST BPDUs associated with VLAN 1 would be discarded. Since IEEE BPDUs associated with VLAN 1 are untagged, they are discarded because the ports in VLAN 1 are tagged. Effectively, the BPDUs are never processed by the Spanning Tree Protocol. STP assumes that there is no better bridge on the network and sets the ports to FORWARDING. This could cause a Layer 2 loop.

The following configuration is correct.

```

Brocade(config)#default-vlan-id 1000
Brocade(config)#vlan 1
Brocade(config-vlan-1)#tagged ethernet 1/1 to 1/2
Brocade(config-vlan-1)#exit
Brocade(config)#interface ethernet 1/1
Brocade(config-if-1/1)#pvst-mode
Brocade(config-if-1/1)#dual-mode
Brocade(config-if-1/1)#exit
Brocade(config)#interface ethernet 1/2
Brocade(config-if-1/2)#pvst-mode
Brocade(config-if-1/2)#dual-mode
Brocade(config-if-1/2)#exit

```

Setting the ports as dual-mode ensures that the untagged IEEE 802.1Q BPDUs reach the VLAN 1 instance.

PVRST compatibility

PVRST, the "rapid" version of per-VLAN spanning tree (PVST), is a Cisco proprietary protocol. PVRST corresponds to the Brocade full implementation of IEEE 802.1w (RSTP). Likewise, PVST, also a Cisco proprietary protocol, corresponds to the Brocade implementation of IEEE 802.1D (STP). When a Brocade device receives PVRST BPDUs on a port configured to run 802.1w, it recognizes and processes these BPDUs and continues to operate in 802.1w mode.

PVRST compatibility is automatically enabled when a port receives a PVRST BPDU.

BPDU guard

In an STP environment, switches, end stations, and other Layer 2 devices use Bridge Protocol Data Units (BPDUs) to exchange information that STP will use to determine the best path for data flow.

The BPDU guard, an enhancement to STP, removes a node that reflects BPDUs back in the network. It enforces the STP domain borders and keeps the active topology predictable by not allowing any network devices behind a BPDU guard-enabled port to participate in STP.

In some instances, it is unnecessary for a connected device, such as an end station, to initiate or participate in an STP topology change. In this case, you can enable the STP BPDU guard feature on the Brocade port to which the end station is connected. STP BPDU guard shuts down the port and puts it into an errdisable state. This disables the connected device's ability to initiate or participate in an STP topology. A log message is then generated for a BPDU guard violation, and a CLI message is displayed to warn the network administrator of a severe invalid configuration. The BPDU guard feature provides a secure response to invalid configurations because the administrator must manually put the interface back in service if errdisable recovery is not enabled.

NOTE

BPDU guard is not supported on tagged ports. It can be configured on a tagged port, but the configuration will have no effect.

Enabling BPDU protection by port

You enable STP BPDU guard on individual interfaces. The feature is disabled by default.

To enable STP BPDU guard on a specific port, enter a command such as the following.

```
Brocade(config) interface ethe 2/1
Brocade(config-if-e1000-2/1)#stp-bpdu-guard
```

Syntax: `[no] stp-bpdu-guard`

The **no** parameter disables the BPDU guard on this interface.

You can also use the multiple interface command to enable this feature on multiple ports at once.

Example

```
Brocade(config)#interface ethernet 1/1 to 1/9
Brocade(config-mif-1/1-1/9)#stp-bpdu-guard
Brocade(config-mif-1/1-1/9)#
```

This will enable stp-bpdu-guard on ports 0/1/1 to 0/1/9

Re-enabling ports disabled by BPDU guard

When a BPDU Guard-enabled port is disabled by BPDU Guard, the Brocade device will place the port in **errdisable** state and display a message on the console indicating that the port is errdisabled (refer to [“BPDU guard status example console messages”](#) on page 1165). In addition, the **show interface** command output will indicate that the port is errdisabled.

Example

```
Brocade#show int e 2
Gigabit Ethernet2 is ERR-DISABLED (bpduguard), line protocol is down
```

To re-enable a port that is in **errdisable** state, you must first disable the port then re-enable it. Enter commands such as the following.

```
Brocade(config)#int e 2
Brocade(config-if-e1000-2)#disable
Brocade(config-if-e1000-2)#enable
```

If you attempt to enable an errdisabled port without first disabling it, the following error message will appear on the console.

```
Brocade(config-if-e1000-2)#enable
Port 2 is errdisabled, do disable first and then enable to enable it
```

Displaying the BPDU guard status

To display the BPDU guard state, enter the **show running configuration** or the **show stp-bpdu-guard** command.

For FastIron X Series devices, enter the **stp-bpdu-guard** command.

```
Brocade#show stp-bpdu-guard
BPDU Guard Enabled on:
Interface Violation
Port 1 No
Port 2 No
Port 3 No
Port 4 No
Port 5 No
Port 6 No
Port 7 No
Port 8 No
Port 9 No
Port 10 No
Port 11 No
Port 12 Yes
Port 13 No
```

BPDU guard status example configurations

Example

The following example shows how to configure BPDU guard at the interface level and to verify the configuration by issuing the **show stp-bpdu-guard** and the **show interface** commands.

```
Brocade(config)#interface ethernet 1
Brocade(config-if-e1000-1)#stp-bpdu-guard
Brocade(config-if-e1000-1)#
Brocade(config-if-e1000-1)#show stp-bpdu-guard
BPDU Guard Enabled on:
Port
1
Brocade(config-if-e1000-1)#
Brocade(config-if-e1000-1)#show interfaces ethernet 1
GigabitEthernet1 is up, line protocol is up
Hardware is GigabitEthernet, address is 000c.dba0.7100 (bia 000c.dba0.7100)
Configured speed auto, actual 100Mbit, configured duplex fdx, actual fdx
Configured mdi mode AUTO, actual MDI
Member of L2 VLAN ID 2, port is untagged, port state is FORWARDING
BPDU guard is Enabled, R00T protect is Disabled
STP configured to ON, priority is level0, flow control enabled
mirror disabled, monitor disabled
Not member of any active trunks
Not member of any configured trunks
No port name
IPG MII 96 bits-time, IPG GMII 96 bits-time
IP MTU 1500 bytes
300 second input rate: 8 bits/sec, 0 packets/sec, 0.00% utilization
300 second output rate: 256 bits/sec, 0 packets/sec, 0.00% utilization
88 packets input, 15256 bytes, 0 no buffer
Received 75 broadcasts, 13 multicasts, 0 unicasts
1 input errors, 0 CRC, 0 frame, 0 ignored
0 runts, 0 giants
4799 packets output, 313268 bytes, 0 underruns
Transmitted 90 broadcasts, 4709
```

BPDU guard status example console messages

A console message such as the following is generated after a BPDU guard violation occurs on a system that is running MSTP.

```
Brocade(config-if-e1000-23)#MSTP: Received BPDU on BPDU guard enabled Port
23,errdisable Port 23
```

A console message such as the following is generated after a BPDU guard violation occurs on a system that is running STP.

```
Brocade(config)#STP: Received BPDU on BPDU guard enabled Port 23 (vlan=1),
errdisable Port 23
```

A console message such as the following is generated after a BPDU guard violation occurs on a system that is running RSTP.

```
Brocade(config-vlan-1)#RSTP: Received BPDU on BPDU guard enabled Port 23
(vlan=1),errdisable Port 23
```

Root guard

The standard STP (802.1D), RSTP (802.1W) or 802.1S does not provide any way for a network administrator to securely enforce the topology of a switched layer 2 network. The forwarding topology of a switched network is calculated based on the root bridge position, along with other parameters. This means any switch can be the root bridge in a network as long as it has the lowest bridge ID. The administrator cannot enforce the position of the root bridge. A better forwarding topology comes with the requirement to place the root bridge at a specific predetermined location. Root Guard can be used to predetermine a root bridge location and prevent rogue or unwanted switches from becoming the root bridge.

When root guard is enabled on a port, it keeps the port in a designated role. If the port receives a superior STP Bridge Protocol Data Units (BPDU), it puts the port into a ROOT-INCONSISTANT state and triggers a log message and an SNMP trap. The ROOT-INCONSISTANT state is equivalent to the BLOCKING state in 802.1D and to the DISCARDING state in 802.1W. No further traffic is forwarded on this port. This allows the bridge to prevent traffic from being forwarded on ports connected to rogue or misconfigured STP bridges.

Once the port stops receiving superior BPDUs, root guard automatically sets the port back to learning, and eventually to a forwarding state through the spanning-tree algorithm.

Configure root guard on all ports where the root bridge should not appear. This establishes a protective network perimeter around the core bridged network, cutting it off from the user network.

NOTE

Root guard may prevent network connectivity if it is improperly configured. Root guard must be configured on the perimeter of the network rather than the core.

NOTE

Root guard is not supported when MSTP is enabled.

Enabling STP root guard

An STP root guard is configured on an interface by entering commands similar to the following.

```
Brocade(config)#interface ethernet 5/5
Brocade(config-if-e10000-5/5)spanning-tree root-protect
```

Syntax: [no] spanning-tree root-protect

Enter the **no** form of the command to disable STP root guard on the port.

Displaying the STP root guard

To display the STP root guard state, enter the **show running configuration** or the **show spanning-tree root-protect** command.

```
Brocade#show spanning-tree root-protect
Root Protection Enabled on:
Port 1
```

Syntax: show spanning-tree root-protect

Displaying the root guard by VLAN

You can display root guard information for all VLANs or for a specific VLAN. For example, to display root guard violation information for VLAN 7.

Syntax: `show spanning-tree [<vlan-id>]`

If you do not specify a `<vlan-id>`, information for all VLANs is displayed. For example, to display root guard violation information for VLAN 7.

```
Brocade#show spanning-tree vlan 7
STP instance owned by VLAN 7
Global STP (IEEE 802.1D) Parameters:

```

Error disable recovery

In case a BPDU guard violation occurs, a port is placed into an errdisable state which is functionally equivalent to a Disable state. Once in an errdisable state, it remains in that state until one of the following methods is used to return the port to an Enabled state.

1. Manually disabling and enabling that interface
2. Automatically, through the errdisable recovery mechanism

The **errdisable recovery interval** command is used to configure a time-out for ports in errdisable state, after which the ports are re-enabled automatically.

When BPDU guard puts a port into errdisabled state, the port remains in errdisabled state unless it is enabled manually by issuing a **disable** command and then the **enable** command on the associated interface or you have errdisable recovery turned on. The **errdisable** command allows you to choose the type of error that automatically reenables the port after a specified amount of time.

Enabling error disable recovery

To enable errdisable recovery for BPDU Guard, enter a command such as the following.

```
Brocade(config)#errdisable recovery cause bpduguard
```

To enable error disable recovery for any reason, enter a command such as the following.

```
Brocade(config)#errdisable recovery cause all
```

Syntax: `errdisable recovery [cause bpduguard | all]`

The **cause** is the reason why the port is in the errdisable state. Valid values are **bpduguard** and **all**.

Use the **bpduguard** parameter to allow the port to recover from the errdisabled state, if the state was caused by a BPDU guard violation.

The **all** parameter allows ports to recover from an errdisabled state caused by any reason, for example, a BPDU Guard violation or loop detection violation.

Setting the recovery interval

The **errdisable recovery interval** command allows you to configure a timeout for ports in errdisabled state, after which the ports are reenabled automatically. To set the errdisable recovery time-out interval, enter a command such as the following.

```
Brocade(config)#errdisable recovery interval 20
```

Syntax: [no] **errdisable recovery interval** <seconds>

The **seconds** parameter allows you to set the timeout value for the recovery mechanism when the port is in an errdisabled state. Once this timeout value expires, the ports are automatically re-enabled. Valid values are from 10 to 65535 seconds (10 seconds to 24 hours).

Displaying the error disable recovery state by interface

The port status of errdisabled displays in the output of the **show interface** and the **show interface brief** commands. In this example, errdisable is enabled on interface ethernet 1 and errdisable is enabled because of a BPDU guard violation.

```
Brocade#show interfaces ethernet 1
GigabitEthernet1 is ERR-DISABLED (bpduguard), line protocol is down
BPDU guard is Enabled, ROOT protect is Disabled
Hardware is GigabitEthernet, address is 000c.dba0.7100 (bia 000c.dba0.7100)
Configured speed auto, actual unknown, configured duplex fdx, actual unknown
Configured mdi mode AUTO, actual unknown
Member of L2 VLAN ID 2, port is untagged, port state is DISABLED
STP configured to ON, priority is level0, flow control enabled
mirror disabled, monitor disabled
Not member of any active trunks
Not member of any configured trunks
No port name
IPG MII 96 bits-time, IPG GMII 96 bits-time
IP MTU 1500 bytes
300 second input rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
300 second output rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
145 packets input, 23561 bytes, 0 no buffer
Received 124 broadcasts, 21 multicasts, 0 unicasts
1 input errors, 0 CRC, 0 frame, 0 ignored
0 runs, 0 giants
5067 packets output, 330420 bytes, 0 underruns
Transmitted 90 broadcasts, 4977 multicasts, 0 unicasts
0 output errors, 0 collisions
```

Displaying the recovery state for all conditions

Use the **show errdisable recovery** command to display all the default error disable recovery state for all possible conditions. In this example, port 6 is undergoing a recovery.

```
Brocade#show errdisable recovery
ErrDisable Reason Timer Status
-----
all reason Disabled
bpduguard Enabled
```

```

Timeout Value: 300 seconds
Interface that will be enabled at the next timeout:
Interface Errdisable reason Time left (sec)
-----
Port 6 bpduguard 297

```

Syntax: show errdisable recovery

Displaying the recovery state by port number and cause

To see which ports are under an errdisabled state, use the **show errdisable summary** command. This command not only shows the port number, but also displays the reason why the port is in an errdisable state and the method used to recover the port. In this example, port 6 is errdisabled for a BPDU guard violation.

```

Brocade#show errdisable summary
Port 6 ERR_Disabled for bpduguard

```

Syntax: show errdisable summary

Errdisable Syslog messages

When the system places a port into an errdisabled state for BPDU guard, a log message is generated. When the errdisable recovery timer expires, a log message is also generated.

A Syslog message such as the following is generated after a port is placed into an errdisable state for BPDU guard.

```

STP: VLAN 50 BPDU-guard port 3 detect (Received BPDU), putting into err-disable
state

```

A Syslog message such as the following is generated after the recovery timer expires.

```

ERR_DISABLE: Interface ethernet 3, err-disable recovery timeout

```

802.1s Multiple Spanning Tree Protocol

Multiple Spanning Tree Protocol (MSTP), as defined in IEEE 802.1s, allows multiple VLANs to be managed by a single STP instance and supports per-VLAN STP. As a result, several VLANs can be mapped to a reduced number of spanning-tree instances. This ensures loop-free topology for one or more VLANs that have the similar layer-2 topology. The Brocade implementation supports up to 16 spanning tree instances in an MSTP enabled bridge which means that it can support up to 16 different Layer 2 topologies. The spanning tree algorithm used by MSTP is RSTP which provides quick convergence.

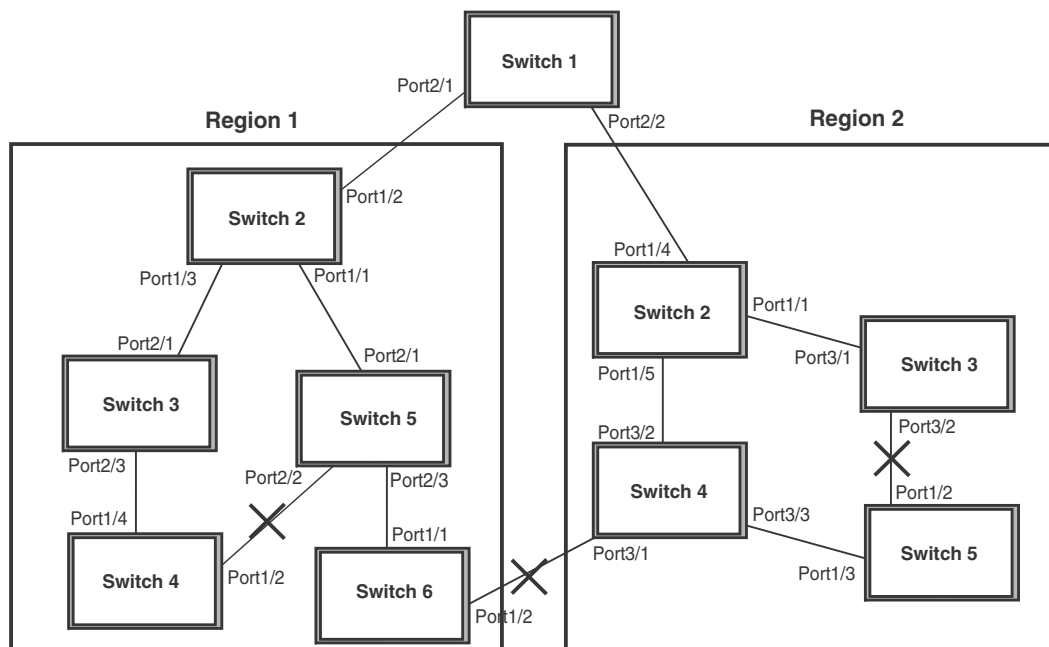

Multiple spanning-tree regions

Using MSTP, the entire network runs a common instance of RSTP. Within that common instance, one or more VLANs can be individually configured into distinct regions. The entire network runs the common spanning tree instance (CST) and the regions run a local instance. The local instance is known as Internal Spanning Tree (IST). The CST treats each instance of IST as a single bridge. Consequently, ports are blocked to prevent loops that might occur within an IST and also throughout the CST. With the exception of the provisions for multiple instances, MSTP operates exactly like RSTP.

For example, in [Figure 156](#) a network is configured with two regions: Region 1 and Region 2. The entire network is running an instance of CST. Each of the regions is running an instance of IST. In addition, this network contains Switch 1 running MSTP that is not configured in a region and consequently is running in the CIST instance. In this configuration, the regions are each regarded as a single bridge to the rest of the network, as is Switch 1. The CST prevents loops from occurring across the network. Consequently, a port is blocked at port 1/2 of switch 4.

Additionally, loops must be prevented in each of the IST instances. Within the IST Region 1, a port is blocked at port 1/2 of switch 4 to prevent a loop in that region. Within Region 2, a port is blocked at port 3/2 of switch 3 to prevent a loop in that region.

FIGURE 156 MSTP configured network

The following definitions describe the STP instances that define an MSTP configuration.

Common Spanning (CST) – CST is defined in 802.1q and assumes one spanning-tree instance for the entire bridged network regardless of the number of VLANs. In MSTP, an MSTP region appears as a virtual bridge that runs CST.

Internal Spanning Tree (IST) – IST is a new terminology introduced in 802.1s. An MSTP bridge must handle at least these two instances: one IST and one or more MSTIs (Multiple Spanning Tree Instances). Within each MST region, the MSTP maintains multiple spanning-tree instances. Instance 0 is a special instance known as IST, which extends CST inside the MST region. IST always exists if the switch runs MSTP. Besides IST, this implementation supports up to 15 MSTIs, numbered from 1 to 4094.

Common and Internal Spanning Trees (CIST) – CIST is a collection of the ISTs in each MST region and the CST that interconnects the MST regions and single spanning trees.

Multiple Spanning Tree Instance (MSTI) – The MSTI is identified by an MST identifier (MSTid) value between 1 and 4094.

MSTP Region – These are clusters of bridges that run multiple instances of the MSTP protocol. Multiple bridges detect that they are in the same region by exchanging their configuration (instance to VLAN mapping), name, and revision-level. Therefore, if you need to have two bridges in the same region, the two bridges must have identical configurations, names, and revision-levels. Also, one or more VLANs can be mapped to one MSTP instance (IST or MSTI) but a VLAN cannot be mapped to multiple MSTP instances.

NOTE

One or more VLANs can be mapped to one MSTP instance (IST or MSTI) but a VLAN cannot be mapped to multiple MSTP instances.

Configuration notes

When configuring MSTP, note the following:

- With MSTP running, enabling static trunk on ports that are members of many VLANs (4000 or more VLANs) will keep the system busy for 20 to 25 seconds.

Configuring MSTP mode and scope

With the introduction of MSTP, a system can be either under MSTP mode or not under MSTP mode. The default state is to **not** be under MSTP mode. MSTP configuration can only be performed in a system under MSTP mode.

With a system configured under MSTP mode, there is a concept called MSTP scope. MSTP scope defines the VLANs that are under direct MSTP control. You cannot run 802.1D or 802.1w on any VLAN (even outside of MSTP scope) and you cannot create topology groups when a system is under MSTP mode. While a VLAN group will still be supported when a system is under MSTP mode, the member VLAN should either be all in the MSTP scope or all out of the MSTP scope.

When a system is configured from non-MSTP mode to MSTP mode, the following changes are made to the system configuration:

- All 802.1D and 802.1w STP instances are deleted regardless of whether the VLAN is inside the MSTP scope or not
- All topology groups are deleted
- Any GVRP configuration is deleted
- Any VSRP configuration is deleted
- Single-span (if configured) is deleted
- MRP running on a VLAN inside MSTP scope is deleted

- The CIST is created and all VLANs inside the MSTP scope are attached with the CIST

Make sure that no physical layer-2 loops exist prior to switching from non-MSTP mode to MSTP mode. If, for example, you have an L2 loop topology configured as a redundancy mechanism before you perform the switch, a Layer 2 storm should be expected.

To configure a system into MSTP mode, use the following command at the Global Configuration level.

```
Brocade(config)#mstp scope all
```

Syntax: [no] mstp scope all

NOTE

MSTP is not operational however until the **mstp start** command is issued as described in [“Activating MSTP on a switch”](#) on page 1178.

Once the system is configured into MSTP mode, CIST (sometimes referred to as “instance 0”) is created and all existing VLANs inside the MSTP scope are controlled by CIST. In addition, whenever you create a new VLAN inside MSTP scope, it is put under CIST control by default. In the Brocade MSTP implementation however, a VLAN ID can be pre-mapped to another MSTI as described in [“Configuring an MSTP instance”](#) on page 1175. A VLAN whose ID is pre-mapped, will attach to the specified MSTI instead of to the CIST when created.

NOTE

Once under MSTP mode, CIST always controls all ports in the system. If you do not want a port to run MSTP, configure the **no spanning-tree** command under the specified interface configuration.

Using the [no] option on a system that is configured for MSTP mode changes the system to non-MSTP mode. When this switch is made, all MSTP instances are deleted together with all MSTP configurations. ALL VLANs inside the original MSTP scope will not run any Layer-2 protocols after the switch.

Reduced occurrences of MSTP reconvergence

When a VLAN is deleted, the Brocade device retains the associated VLAN to MSTI mapping instead of deleting it from the configuration. This way, a VLAN can be pre-mapped to an MSTI and MSTP reconvergence may not be necessary when a VLAN is added to or deleted from the configuration. As long as the VLAN being created or deleted is pre-mapped to an MSTI, and the VLAN to MSTI mapping has not changed, MSTP reconvergence will not occur.

NOTE

MSTP reconvergence occurs when the VLAN to MSTI mapping is changed using the **mstp instance** command.

You can optionally remove VLAN to MSTI mappings from the configuration. Refer to [“Deleting a VLAN to MSTI mapping”](#) on page 1173.

The following shows an example application.

Example application of MSTP reconvergence

The following example shows the running configuration file before and after deleting a VLAN from the configuration. The VLAN to MSTI mapping is retained in the running configuration, even after the VLAN is deleted.

```

Brocade(config-vlan-20)#show run
Current configuration:
!
ver 04.2.00bT3e1
!
!
vlan 1 name DEFAULT-VLAN by port
    no spanning-tree
!
vlan 10 by port
    tagged ethe 1 to 2
    no spanning tree
!
vlan 20 by port                                <----- VLAN 20 configuration
    tagged ethe 1 to 2
    no spanning-tree
!
mstp scope all
mstp instance 0 vlan 1
mstp instance 1 vlan 20
mstp start
some lines ommitted for brevity...

Brocade(config-vlan-20)#no vlan 20            <----- VLAN 20 deleted

Brocade(config-vlan-20)#show run
Current configuration:
!
ver 04.2.00bT3e1
!
!
vlan 1 name DEFAULT-VLAN by port
    no spanning-tree
!
vlan 10 by port
    tagged ethe 1 to 2
    no spanning-tree
!
mstp scope all
mstp instance 0 vlan 1
mstp instance 1 vlan 10
mstp instance 1 vlan 20
mstp start
some lines ommitted for brevity...
<----- VLAN to MSTI mapping kept in
running configuration, even though
VLAN 20 was deleted

```

Deleting a VLAN to MSTI mapping

You can optionally remove a VLAN to MSTI mapping using the **no mstp instance** command. To do so, enter a command such as the following.

```
Brocade(config)#no mstp instance 7 vlan 4 to 7
```

This command deletes the VLAN to MSTI mapping from the running configuration and triggers an MSTP reconvergence.

Syntax: **no mstp instance** <instance-number> **vlan** <vlan-id> | **vlan-group** <group-id>]

The **instance** parameter defines the number for the instance of MSTP that you are deleting.

The **vlan** parameter identifies one or more VLANs or a range of VLANs to the instance defined in this command.

The **vlan-group** parameter identifies one or more VLAN groups to the instance defined in this command.

Viewing the MSTP configuration digest

The MSTP Configuration Digest indicates the occurrence of an MSTP reconvergence. The Configuration Digest is recalculated whenever an MSTP reconvergence occurs. To view the Configuration Digest, use the **show mstp config** command. The following shows an example output.

```
SW-FESX624F+2XG Switch(config-vlan-20)#show mstp config
MSTP CONFIGURATION
-----
Scope          : all system
Name           :
Revision       : 0
Version        : 3 (MSTP mode)
Config Digest: 0x9bbda9c70d91f633e1e145fbcbf8d321
Status        : Started

Instance VLANs
-----
0          1
1          10 20
```

Syntax: **show mstp config**

Configuring additional MSTP parameters

To configure a switch for MSTP, you could configure the name and the revision on each switch that is being configured for MSTP. You must then create an MSTP Instance and assign an ID. VLANs are then assigned to MSTP instances. These instances must be configured on all switches that interoperate with the same VLAN assignments. Port cost, priority and global parameters can then be configured for individual ports and instances. In addition, operational edge ports and point-to-point links can be created and MSTP can be disabled on individual ports.

Each of the commands used to configure and operate MSTP are described in the following:

- [“Setting the MSTP name”](#)
- [“Setting the MSTP revision number”](#)
- [“Configuring an MSTP instance”](#)
- [“Configuring bridge priority for an MSTP instance”](#)
- [“Setting the MSTP global parameters”](#)
- [“Setting ports to be operational edge ports”](#)
- [“Setting automatic operational edge ports”](#)
- [“Setting point-to-point link”](#)
- [“Disabling MSTP on a port”](#)

- “Forcing ports to transmit an MSTP BPDU”
- “Activating MSTP on a switch”

Setting the MSTP name

Each switch that is running MSTP is configured with a name. It applies to the switch which can have many different VLANs that can belong to many different MSTP regions.

To configure an MSTP name, use a command such as the following at the Global Configuration level.

```
Brocade(config)#mstp name Brocade
```

Syntax: [no] mstp name <name>

The **name** parameter defines an ASCII name for the MSTP configuration. The default name is for the name variable to be blank.

Setting the MSTP revision number

Each switch that is running MSTP is configured with a revision number. It applies to the switch which can have many different VLANs that can belong to many different MSTP regions.

To configure an MSTP revision number, use a command such as the following at the Global Configuration level.

```
Brocade(config)#mstp revision 4
```

Syntax: [no] mstp revision <revision-number>

The **revision** parameter specifies the revision level for MSTP that you are configuring on the switch. It can be a number from 0 and 65535. The default revision number is 0.

Configuring an MSTP instance

An MSTP instance is configured with an MSTP ID for each region. Each region can contain one or more VLANs. The Brocade implementation of MSTP allows you to assign VLANs or ranges of VLANs to an MSTP instance before or after they have been defined. If pre-defined, a VLAN will be placed in the MSTI that it was assigned to immediately when the VLAN is created. Otherwise, the default operation is to condition of assign all new VLANs to the CIST. VLANs assigned to the CIST by default can be moved later to a specified MSTI.

To configure an MSTP instance and map one or more VLANs to that MSTI, use a command such as the following at the Global Configuration level.

```
Brocade(config)#mstp instance 7 vlan 4 to 7
```

Syntax: [no] mstp instance <instance-number> [vlan <vlan-id> | vlan-group <group-id>]

The **instance** parameter defines the number for the instance of MSTP that you are configuring. The value 0 (which identifies the CIST) cannot be used. You can have up to 15 instances, number 1 – 4094.

The **vlan** parameter assigns one or more VLANs or a range of VLANs to the instance defined in this command.

The **vlan-group** parameter assigns one or more VLAN groups to the instance defined in this command.

The **no** option moves a VLAN or VLAN group from its assigned MSTI back into the CIST.

NOTE

The system does not allow an MSTI without any VLANs mapped to it. Consequently, removing all VLANs from an MSTI, deletes the MSTI from the system. The CIST by contrast will exist regardless of whether or not any VLANs are assigned to it or not. Consequently, if all VLANs are moved out of a CIST, the CIST will still exist and functional.

Configuring bridge priority for an MSTP instance

Priority can be configured for a specified instance. To configure priority for an MSTP instance, use a command such as the following at the Global Configuration level.

```
Brocade(config)#mstp instance 1 priority 8192
```

Syntax: [no] mstp instance <instance-number> priority <priority-value>

The <instance-number> variable is the number for the instance of MSTP that you are configuring.

You can set a **priority** to the instance that gives it forwarding preference over lower priority instances within a VLAN or on the switch. A higher number for the priority variable means a lower forwarding priority. Acceptable values are 0 - 61440 in increments of 4096. The default value is 32768.

Setting the MSTP global parameters

MSTP has many of the options available in RSTP as well as some unique options. To configure MSTP Global parameters for all instances on a switch.

```
Brocade(config)#mstp force-version 0 forward-delay 10 hello-time 4 max-age 12
max-hops 9
```

Syntax: [no] mstp force-version <mode-number> forward-delay <value> hello-time <value>
max-age <value> max-hops <value>

The **force-version** parameter forces the bridge to send BPDUs in a specific format. You can specify one of the following <mode-number> values:

- 0 – The STP compatibility mode. Only STP BPDUs will be sent. This is equivalent to single STP.
- 2 – The RSTP compatibility mode. Only RSTP BPDUS will be sent. This is equivalent to single STP.
- 3 – MSTP mode. In this default mode, only MSTP BPDUS will be sent.

The **forward-delay** <value> specifies how long a port waits before it forwards an RST BPDU after a topology change. This can be a value from 4 – 30 seconds. The default is 15 seconds.

The **hello-time** <value> parameter specifies the interval between two hello packets. The parameter can have a value from 1 – 10 seconds. The default is 2 seconds.

The **max-age** <value> parameter specifies the amount of time the device waits to receive a hello packet before it initiates a topology change. You can specify a value from 6 – 40 seconds, where the value adheres to the following formula.

max age equal to or greater than 2 x (hello-time + 1) AND max age equal to or greater than 2 x (forward-delay – 1)

The default max-age is 20 seconds.

The **max-hops** *<value>* parameter specifies the maximum hop count. You can specify a value from 1 – 40 hops. The default value is 20 hops.

Setting ports to be operational edge ports

You can define specific ports as edge ports for the region in which they are configured to connect to devices (such as a host) that are not running STP, RSTP, or MSTP. If a port is connected to an end device such as a PC, the port can be configured as an edge port. To configure ports as operational edge ports enter a command such as the following.

```
Brocade(config)#mstp admin-edge-port ethernet 3/1
```

Syntax: [no] **mstp admin-edge-port ethernet** *<port>*

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Setting automatic operational edge ports

You can configure a Layer 3 switch to automatically set a port as an operational edge port if the port does not receive any BPDUs since link-up. If the port receives a BPDU later, it is automatically reset to become an operational non-edge port. This feature is set globally to apply to all ports on a router where it is configured. This feature is configured as shown in the following.

```
Brocade(config)#mstp edge-port-auto-detect
```

Syntax: [no] **mstp edge-port-auto-detect**

NOTE

If this feature is enabled, it takes the port about 3 seconds longer to come to the enable state.

Setting point-to-point link

You can set a point-to-point link between ports to increase the speed of convergence. To create a point-to-point link between ports, use a command such as the following at the Global Configuration level.

```
Brocade(config)#mstp admin-pt2pt-mac ethernet 2/5 ethernet 4/5
```

Syntax: [no] **mstp admin-pt2pt-mac ethernet** *<port>*

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Disabling MSTP on a port

To disable MSTP on a specific port, use a command such as the following at the Global Configuration level.

```
Brocade(config)#mstp disable ethernet 2/1
```

Syntax: [no] mstp disable ethernet <port>

The <port> variable specifies the location of the port for which you want to disable MSTP. Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

When a port is disabled for MSTP, it behaves as blocking for all the VLAN traffic that is controlled by MSTIs and the CIST.

Forcing ports to transmit an MSTP BPDU

To force a port to transmit an MSTP BPDU, use a command such as the following at the Global Configuration level.

```
Brocade(config)#mstp force-migration-check ethernet 3/1
```

Syntax: [no] mstp force-migration-check ethernet <port>

The <port> variable specifies the port or ports from which you want to transmit an MSTP BPDU. Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Activating MSTP on a switch

MSTP scope must be enabled on the switch as described in [“Configuring MSTP mode and scope”](#) on page 1171 before MSTP can be enabled.

To enable MSTP on your switch, use the following at the Global Configuration level.

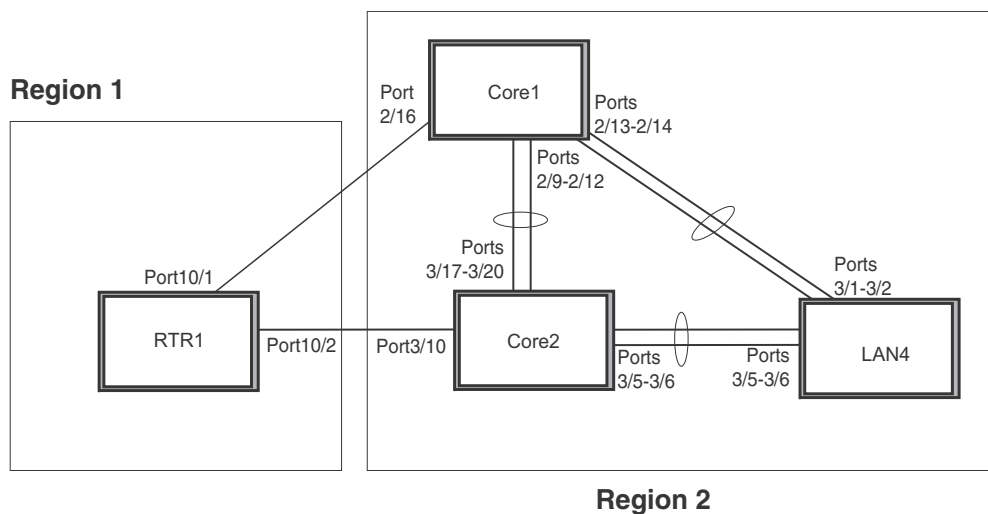

```
Brocade(config)#mstp start
```

Syntax: [no] mstp start

The [no] option disables MSTP from operating on a switch.

Example of an MSTP configuration

In [Figure 157](#) four Brocade device routers are configured in two regions. There are four VLANs in four instances in Region 2. Region 1 is in the CIST.

FIGURE 157 Sample MSTP configuration**RTR1 on MSTP configuration**

```

Syntax: `show mstp <instance-number>`

The `<instance-number>` variable specifies the MSTP instance that you want to display information for.

TABLE 202 Output from Show MSTP

Field	Description
MSTP Instance	The ID of the MSTP instance whose statistics are being displayed. For the CIST, this number is 0.
VLANs	The number of VLANs that are included in this instance of MSTP. For the CIST this number will always be 1.
Bridge Identifier	The MAC address of the bridge.
Bridge MaxAge sec	Displays configured Max Age.
Bridge Hello sec	Displays configured Hello variable.
Bridge FwdDly sec	Displays configured FwdDly variable.
Bridge Hop cnt	Displays configured Max Hop count variable.
Root MaxAge sec	Max Age configured on the root bridge.
Root Hello sec	Hello interval configured on the root bridge.

TABLE 202 Output from Show MSTP (Continued)

Field	Description
Root FwdDly sec	FwdDly interval configured on the root bridge.
Root Hop Cnt	Current hop count from the root bridge.
Root Bridge	Bridge identifier of the root bridge.
ExtPath Cost	The configured path cost on a link connected to this port to an external MSTP region.
Regional Root Bridge	The Regional Root Bridge is the MAC address of the Root Bridge for the local region.
IntPath Cost	The configured path cost on a link connected to this port within the internal MSTP region.
Designated Bridge	The MAC address of the bridge that sent the best BPDU that was received on this port.
Root Port	Port indicating shortest path to root. Set to "Root" if this bridge is the root bridge.
Port Num	The port number of the interface.
Pri	The configured priority of the port. The default is 128.
PortPath Cost	Configured or auto detected path cost for port.
P2P Mac	Indicates if the port is configured with a point-to-point link: <ul style="list-style-type: none"> • T – The port is configured in a point-to-point link • F – The port is not configured in a point-to-point link
Edge	Indicates if the port is configured as an operational edge port: <ul style="list-style-type: none"> • T – indicates that the port is defined as an edge port. • F – indicates that the port is not defined as an edge port
Role	The current role of the port: <ul style="list-style-type: none"> • Master • Root • Designated • Alternate • Backup • Disabled
State	The port current spanning tree state. A port can have one of the following states: <ul style="list-style-type: none"> • Forwarding • Discarding • Learning • Disabled
Designated Cost	Port path cost to the root bridge.
Max Hop cnt	The maximum hop count configured for this instance.
Root Hop cnt	Hop count from the root bridge.

Displaying MSTP information for a specified instance

The following example displays MSTP information specified for an MSTP instance.

```
Brocade#show mstp 1
MSTP Instance 1 - VLANs: 2
-----
Bridge          Max RegionalRoot    IntPath   Designated    Root    Root
Identifier      Hop Bridge          Cost       Bridge        Port    Hop
hex             cnt hex              hex           hex           cnt
8001000cdb80af01 20 8001000cdb80af01 0           8001000cdb80af01 Root    20

Port  Pri PortPath  Role          State        Designa-  Designated
Num    Cost                                     ted cost  bridge
3/1   128 2000          MASTER       FORWARDING  0         8001000cdb80af01
```

Refer to [Table 202](#) for details about the display parameters.

Displaying MSTP information for CIST instance 0

Instance 0 is the Common and Internal Spanning Tree Instance (CIST). When you display information for this instance there are some differences with displaying other instances. The following example displays MSTP information for CIST Instance 0.

```
Brocade#show mstp 0
MSTP Instance 0 (CIST) - VLANs: 1
-----
Bridge          Bridge Bridge Bridge Bridge Root   Root   Root   Root
Identifier      MaxAge Hello FwdDly Hop   MaxAge Hello FwdDly Hop
hex             sec   sec   sec   cnt   sec   sec   sec   cnt
8000000cdb80af01 20    2    15   20    20    2    15   19
Root           ExtPath RegionalRoot    IntPath   Designated    Root
Bridge         Cost       Bridge          Cost       Bridge        Port
hex            hex              hex           hex
8000000480bb9876 2000      8000000cdb80af01 0           8000000480bb9876 3/1
Port  Pri PortPath  P2P Edge Role   State        Designa-  Designated
Num    Cost      Mac Port          ted cost  bridge
3/1   128 2000      T   F   ROOT    FORWARDING  0         8000000480bb9876
```

To display details about the MSTP configuration, enter the following command.

```
Brocade#show mstp conf
MSTP CONFIGURATION
-----
Name       : Reg1
Revision   : 1
Version    : 3 (MSTP mode)
Status     : Started

Instance VLANs
-----
0          4093
```

802.1s Multiple Spanning Tree Protocol

To display details about the MSTP that is configured on the device, enter the following command.

```
Brocade#show mstp detail
MSTP Instance 0 (CIST) - VLANs: 4093
-----
Bridge: 800000b000c00000 [Priority 32768, SysId 0, Mac 00b000c00000]
FwdDelay 15, HelloTime 2, MaxHops 20, TxHoldCount 6
Port 6/54 - Role: DESIGNATED - State: FORWARDING
PathCost 20000, Priority 128, OperEdge T, OperPt2PtMac F, Boundary T
Designated - Root 800000b000c00000, RegionalRoot 800000b000c00000,
Bridge 800000b000c00000, ExtCost 0, IntCost 0
ActiveTimers - helloWhen 1
MachineState - PRX-DISCARD, PTX-IDLE, PPM-SENDING_RSTP, PIM-CURRENT
PRT-ACTIVE_PORT, PST-FORWARDING, TCM-INACTIVE
BPDUs - Rcvd MST 0, RST 0, Config 0, TCN 0
Sent MST 6, RST 0, Config 0, TCN 0
```

Refer to [Table 202](#) for explanation about the parameters in the output.

Syntax: `show mstp [<mstp-id> | configuration | detail] [| begin <string> | exclude <string> | include <string>]`

Enter an MSTP ID for <mstp-id>.

Base Layer 3 and Routing Protocols

Table 203 lists the individual Brocade FastIron switches and the base Layer 3 features they support. These features are supported in the base Layer 3, edge Layer 3, and full Layer 3 software images, except where explicitly noted.

TABLE 203 Supported base Layer 3 features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6450
Static IP routing	Yes	Yes	Yes	Yes	Yes
Layer 3 system parameter limits	Yes	Yes	Yes	Yes	Yes
Static ARP entries	Yes (up to 6,000)	No	Yes (up to 1,000)	Yes (up to 1,000)	Yes (up to 1,024)
RIP V1 and V2 (Static RIP support only in the base Layer 3 image. The Brocade device with base Layer 3 does not learn RIP routes from other Layer 3 devices. However, the device does advertise directly connected routes.)	Yes	Yes	Yes	Yes	Yes
Redistribution of IP static routes into RIP	Yes	Yes	Yes	Yes	Yes
RIP default route learning	Yes	Yes	Yes	Yes	Yes
Route loop prevention: <ul style="list-style-type: none"> • Split horizon • Poison reverse 	Yes	Yes	Yes	Yes	Yes
Route-only support (supported with edge Layer 3 and full Layer 3 images only)	Yes	Yes	Yes	Yes	Yes

NOTE

ICX 6430 devices does not support Layer 3 features. RIP and OSPF are available as part of Premium license.

NOTE

Layer 2 with base Layer 3 images provide static RIP support. The device does not learn RIP routes from other Layer 3 devices. However, the device does advertise directly connected routes and can be configured to dynamically learn default routes. Brocade recommends that you deploy these devices only at the edge of your network, because incoming traffic can learn directly connected routes advertised by the Brocade device, but outgoing traffic to other devices must use statically configured or default routes.

TCAM entries in FWS devices

The size of the TCAM in FWS devices is limited to 1024 routing entries. When this limit is reached, the following warning message is displayed.

```
No free TCAM entry available. System will be unstable. Please reboot system.
```

At the same time, the following syslog message is generated.

```
System: No Free Tcam Entry available. System will be unstable.
```

You must reboot the device when you see these messages.

Adding a static IP route

To add a static IP route, enter a command such as the following at the global CONFIG level of the CLI.

```
Brocade(config)#ip route 209.157.2.0 255.255.255.0 192.168.2.1
```

This command adds a static IP route to the 209.157.2.x/24 subnet.

Syntax: [no] ip route <dest-ip-addr> <dest-mask> <next-hop-ip-addr> [<metric>] [tag <num>]

or

Syntax: [no] ip route <dest-ip-addr>/<mask-bits> <next-hop-ip-addr> [<metric>] [tag <num>]

On FastIron X Series devices, you can add up to 2048 static IP routes.

The <dest-ip-addr> variable is the route destination. The <dest-mask> variable is the network mask for the route destination IP address. Alternatively, you can specify the network mask information by entering a forward slash followed by the number of bits in the network mask. For example, you can enter 192.0.0.0 255.255.255.0 as 192.0.0.0/.24. To configure a default route, enter 0.0.0.0 for <dest-ip-addr> and 0.0.0.0 for <dest-mask> (or 0 for the <mask-bits> variable if you specify the address in CIDR format). Specify the IP address of the default gateway using the <next-hop-ip-addr> variable.

The <next-hop-ip-addr> variable is the IP address of the next hop router (gateway) for the route.

The <metric> variable specifies the cost of the route and can be a number from 1 through 16. The default is 1. The metric is used by RIP. If you do not enable RIP, the metric is not used.

The tag <num> parameter specifies the tag value of the route. The possible value is from 0 through 4294967295. The default value is 0.

NOTE

You cannot specify **null0** or another interface as the next hop in the base Layer 3 image.

Adding a static ARP entry

NOTE

Adding a static ARP entry is supported on FastIron X Series and Brocade FCX Series devices. It is *not* supported on FastIron WS Series devices.

Static entries are useful in cases where you want to pre-configure an entry for a device that is not connected to the Brocade device, or you want to prevent a particular entry from aging out. The software removes a dynamic entry from the ARP cache if the ARP aging interval expires before the entry is refreshed. Static entries do not age out, regardless of whether the Brocade device receives an ARP request from the device that has the entry address. The software places a static ARP entry into the ARP cache as soon as you create the entry.

To add a static ARP entry, enter a command such as the following at the global CONFIG level of the CLI.

```
Brocade(config)#arp 1 209.157.22.3 aaaa.bbbb.cccc ethernet 3
```

This command adds a static ARP entry that maps IP address 209.157.22.3 to MAC address aaaa.bbbb.cccc. The entry is for a MAC address connected to Brocade port 3.

Syntax: **[no]** **arp** *<num>* *<ip-addr>* *<mac-addr>* **ethernet** *<port>*

The *<num>* variable specifies the entry number. You can specify a number from 1 up to the maximum number of static entries allowed on the device. You can allocate more memory to increase this amount. To do so, enter the **system-max ip-static-arp** *<num>* command at the global CONFIG level of the CLI.

The *<ip-addr>* variable specifies the IP address of the device that has the MAC address of the entry.

The *<mac-addr>* variable specifies the MAC address of the entry.

The **ethernet** *<port>* parameter specifies the port number attached to the device that has the MAC address of the entry. Specify the *<port>* variable in one of the following formats:

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

The **clear arp** command clears learned ARP entries but does not remove any static ARP entries.

Modifying and displaying Layer 3 system parameter limits

This section shows how to view and configure some of the Layer 3 system parameter limits.

Layer 3 configuration notes

- Changing the system parameters reconfigures the device memory. Whenever you reconfigure the memory on a Brocade device, you must save the change to the startup-config file, and then reload the software to place the change into effect.
- The Layer 3 system parameter limits for FastIron IPv6 models are automatically adjusted by the system and cannot be manually modified. Refer to [“FastIron second generation modules”](#) on page 1190.

FWS with base Layer 3

NOTE

This section applies to the FastIron WS base Layer 3 code. It does not apply to the FastIron X Series and Brocade FCX Series devices.

The base Layer 3 code uses ternary content-addressable memory (TCAM) for IP routing, access lists, MAC-based VLANs, and other features. The default value for TCAM is 256 routes.

You can set the TCAM number reserved for IP routing using the **system-max** command.

```
Brocade(config)#system-max hw-ip-route-tcam 450
```

Syntax: [no] **system-max hw-ip-route-tcam** <num>

The <num> variable specifies a value from 64 through 1020. The default is 256.

The **show ip route** command displays the usage of TCAM in routing.

```
Brocade#show ip route
Total number of IP routes: 29
Route TCAM: total 64, used 64, add HW route failure=34

Start index: 1  D:Connected  R:RIP  S:Static  O:OSPF  *:Candidate default
      Destination      NetMask      Gateway      Port      Cost      Type
1      2.2.10.0          255.255.255.0  0.0.0.0      v10        1          D
2      2.2.11.0          255.255.255.0  0.0.0.0      v11        1          D
...
```

In this example, *add HW route failure* shows the number of failures in installing routing TCAM.

The base Layer 3 code installs routing TCAM for the interface subnet and static routes. A packet is routed in hardware if its destination IP address matches the interface or stack route subnet, and the next hop or destination ARP is resolved. The unknown unicast packets have destination IP addresses that do not match any static route or interface subnets.

The handling of unknown unicast packets differs depending on TCAM availability. For example, for a system that never encounters an out-of-TCAM situation, If the default route is not configured or its next hop ARP is not resolved, all unknown unicast packets are handled based on the default Layer 2 behavior. They are either dropped in hardware if **route-only** is configured or VLAN-flooded in hardware.

If the default route is configured and its next hop ARP is resolved, unknown unicast packets are hardware-routed to the next hop, and not VLAN-flooded.

Once the device runs out of TCAM, it traps the unknown unicast packets to the CPU for processing. If the default route is defined and its next hop ARP is resolved, the packets are routed by the CPU. Otherwise, they follow the default Layer 2 behavior. Because the base Layer 3 code does not allow **route-only** configurations, these packets are VLAN-flooded.

The system does not change this CPU-handling behavior back to hardware switching even when TCAM again becomes available.

FastIron first generation modules

You can configure the following Layer 3 system parameters on FastIron X Series first generation modules:

- Number of IP next hops and IP route entries
- Number of hardware logical interfaces (physical port and VLAN pairs)
- Number of multicast output interfaces (clients)

These parameters are automatically enabled with pre-defined default values. You can, however, adjust these values to conform with your network topology.

To display the current settings for the Layer 3 system parameters, use the **show default value** command. Refer to [“Displaying Layer 3 system parameter limits”](#) on page 1191.

To modify the default settings for the Layer 3 system parameters, use the **system max** command at the global CONFIG level of the CLI. Refer to [“Modifying Layer 3 system parameter limits on first generation modules”](#) on page 1189.

Modifying Layer 3 system parameter limits on first generation modules

NOTE

The commands in this section are supported on FastIron X Series devices only.

The Layer 3 system parameter limits share the same hardware memory space and, by default, consume all of the hardware memory allocated for these Layer 3 limits. Therefore, to increase the limit for one of the parameters, you must first decrease one or both of the other parameters' limits. If you enter a value that exceeds the memory limit, an error message displays and the configuration will not take effect.

For example, if the network topology has a smaller number of IP next hops and routes, but has numerous multicast output interfaces, you could decrease the number of IP next hops and routes, and then increase the number of multicast output interfaces. To do so, enter commands such as the following.

```
Brocade(config)#system-max hw-ip-next-hop 1024
Brocade(config)#system-max hw-ip-mcast-mll 2048
Brocade(config)#write memory
Brocade(config)#reload
```

Likewise, if the network topology does not have a large number of VLANs, and the VLANs configured on physical ports are not widely distributed, you could decrease the number of hardware logical interfaces, and then increase the number of IP next hops and multicast output interfaces. To do so, enter commands such as the following.

```
Brocade(config)#system-max hw-logical-interface 2048
Brocade(config)#system-max hw-ip-next-hop 3072
Brocade(config)#system-max hw-ip-mcast-mll 2048
Brocade(config)#write memory
Brocade(config)#reload
```

Syntax: **system-max hw-ip-next-hop** *<num>*

Syntax: **system-max hw-logical-interface** *<num>*

Syntax: **system-max hw-ip-mcast-mll** *<num>*

NOTE

The **system-max** commands are not supported on IPv6 devices. Refer to [“FastIron second generation modules”](#) on page 1190.

The **hw-ip-next-hop** *<num>* parameter specifies the maximum number of IP next hops and routes supported on the device. Note that the maximum number includes unicast next hops and multicast route entries. Enter a number from 100 through 6144. The default is 2048.

You can define the maximum number of hops on FastIron X Series devices using the **hw-ip-next-hop** *<num>* parameter with the following first generation modules installed:

- SX-FI424F
- SX-FI424C
- SX-FI424P
- SX-FI424HF
- SX-FI42XG
- SX-FI42XGW

If these modules are not installed, then the maximum number of hops is automatically set and is not configurable.

The **hw-logical-interface** *<num>* parameter specifies the number of hardware logical interface pairs (physical port and VLAN pairs) supported on the device. Enter a number from 0 through 4096. When this parameter is set to 4096 (the maximum), the limit is not enforced. If you enter a number less than 4096, the limit is the total number of physical port and VLAN pairs that are IP-enabled in the system. The default is 4096.

The **hw-ip-mcast-mll** *<num>* parameter specifies the maximum number of multicast output interfaces (clients) supported on the device. If a given source or group has clients in *n* tagged VLANs on the router, then *n* entries are consumed for that source or group entry. Enter a number from 0 through 4096. The default is 1024.

FastIron second generation modules

FastIron IPv6 models support the same Layer 3 system parameters that use hardware memory as do FastIron IPv4 models. However, there are some configuration differences between second generation modules and first generation modules. The differences are as follows:

- Number of IP next hops and IP route entries – 6144 maximum and default value. The system automatically calculates this value, based on the maximum number of VLANs supported systemwide.

- Number of hardware logical interfaces (physical port and VLAN pairs) – This value is the same as the maximum number of VLANs supported systemwide, so it is not configurable nor displayed in the **show default value** output in second generation modules.
- Number of multicast output interfaces (clients) – 3072 maximum. This value is fixed in second generation modules and cannot be modified. This system parameter occupies its own hardware memory space.

To display the current settings for the Layer 3 system parameters, use the **show default value** command. Refer to [“Displaying Layer 3 system parameter limits”](#) on page 1191.

FastIron third generation modules

The default value of next hop entries on FastIron X Series devices with the following third generation modules installed is 16384. This value is predefined and not editable.

- SX-FI48GPP
- SX-FI-2XG
- SX-FI-8XG
- SX-FI-24HF
- SX-FI-24GPP

If the FastIron X Series device is installed with first generation or second generation modules, the system automatically calculates the default value for these modules.

Displaying Layer 3 system parameter limits

To display the Layer 3 system parameter defaults, maximum values, and current values, enter the **show default value** command at any level of the CLI.

The following example shows output on a FastIron X Series with first generation modules.

```
Brocade#show default value
```

```
sys log buffers:50          mac age time:300 sec          telnet sessions:5
ip arp age:10 min          bootp relay max hops:4      ip ttl:64 hops
ip addr per intf:24
igmp group memb.:140 sec   igmp query:60 sec
ospf dead:40 sec          ospf hello:10 sec          ospf retrans:5 sec
ospf transit delay:1 sec
```

System Parameters	Default	Maximum	Current
ip-arp	4000	64000	4000
ip-static-arp	512	1024	512

some lines omitted for brevity....

hw-ip-next-hop	2048	6144	2048
hw-logical-interface	4096	4096	4096
hw-ip-mcast-ml1	1024	4096	1024

Modifying and displaying Layer 3 system parameter limits

The following example shows output on a FastIron X Series with second generation modules.

```
Brocade#show default value

```

Configuring RIP

If you want the Brocade device to use Routing Information Protocol (RIP), you must enable the protocol globally, and then enable RIP on individual ports. When you enable RIP on a port, you also must specify the version (version 1 only, version 2 only, or version 1 compatible with version 2).

Optionally, you also can set or change the following parameters:

- Route redistribution – You can enable the software to redistribute static routes from the IP route table into RIP. Redistribution is disabled by default.
- Learning of default routes – The default is disabled.
- Loop prevention (split horizon or poison reverse) – The default is poison reverse.

Enabling RIP

RIP is disabled by default. You must enable the protocol both globally and on the ports on which you want to use RIP.

To enable RIP globally, enter the following command.

```
Brocade(config)#router rip
```

Syntax: [no] router rip

To enable RIP on a port and specify the RIP version, enter commands such as the following.

```
Brocade(config-rip-router)#interface ethernet 1
Brocade(config-if-e1000-1)#ip rip v1-only
```

These commands change the CLI to the configuration level for port 1 and enable RIP version 1 on the interface. You must specify the version.

Syntax: interface ethernet <port>

Syntax: [no] ip rip v1-only | v1-compatible-v2 | v2-only

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Enabling redistribution of IP static routes into RIP

By default, the software does not redistribute the IP static routes in the route table into RIP. To configure redistribution, perform the following tasks.

1. Configure redistribution filters (optional).

You can configure filters to permit or deny redistribution for a route based on the route metric. You also can configure a filter to change the metric. You can configure up to 64 redistribution filters. The software uses the filters in ascending numerical order and immediately takes the action specified by the filter. Thus, if filter 1 denies redistribution of a given route, the software does not redistribute the route, regardless of whether a filter with a higher ID permits redistribution of that route.

NOTE

The default redistribution action is permit, even after you configure and apply a permit or deny filter. To deny redistribution of specific routes, you must configure a deny filter.

NOTE

The option to set the metric is not applicable to static routes.

2. Enable redistribution.

NOTE

If you plan to configure redistribution filters, do not enable redistribution until you have configured the filters.

When you enable redistribution, all types of routes are redistributed into RIP; redistribution is not limited to IP static routes. If you want to deny certain routes from being redistributed into RIP, configure deny filters for those routes before you enable redistribution. You can configure up to 64 RIP redistribution filters. They are applied in ascending numerical order.

NOTE

The default redistribution action is permit, even after you configure and apply redistribution filters to the port. If you want to tightly control redistribution, apply a filter to deny all routes as the last filter (filter ID 64), and then apply filters with lower filter IDs to allow specific routes.

Configuring a redistribution filter

To configure a redistribution filter, enter a command such as the following.

```
Brocade(config-rip-router)#deny redistribute 1 static address 207.92.0.0
255.255.0.0
```

This command denies redistribution of all 207.92.x.x IP static routes.

Syntax: [no] permit | deny redistribute <filter-num> static address <ip-addr> <ip-mask>
[match-metric <value> | set-metric <value>]

The <filter-num> variable specifies the redistribution filter ID. Specify a number from 1 through 64. The software uses the filters in ascending numerical order. Thus, if filter 1 denies a route from being redistributed, the software does not redistribute that route even if a filter with a higher ID permits redistribution of the route.

The **static address** <ip-addr> <ip-mask> parameters apply redistribution to the specified network and subnet address. Use 0 to specify “any”. For example, “207.92.0.0 255.255.0.0” means “any 207.92.x.x subnet”. However, to specify any subnet (all subnets match the filter), enter **static address 255.255.255.255 255.255.255.255**.

The **match-metric** <value> parameter applies redistribution to those routes with a specific metric value. Possible values are from 1 through 15.

The **set-metric** <value> parameter sets the RIP metric value that will be applied to the routes imported into RIP.

NOTE

The **set-metric** parameter does not apply to static routes.

The following command denies redistribution of a 207.92.x.x IP static route only if the route metric is 5.

```
Brocade(config-rip-router)#deny redistribute 2 static address 207.92.0.0
255.255.0.0 match-metric 5
```

The following commands deny redistribution of all routes except routes for 10.10.10.x and 20.20.20.x.

```
Brocade(config-rip-router)#deny redistribute 64 static address 255.255.255.255
255.255.255.255
Brocade(config-rip-router)#permit redistribute 1 static address 10.10.10.0
255.255.255.0
Brocade(config-rip-router)#permit redistribute 2 static address 20.20.20.0
255.255.255.0
```

Enabling redistribution

After you configure redistribution parameters, you must enable redistribution.

To enable RIP redistribution, enter the following command.

```
Brocade(config-rip-router)#redistribution
```

Syntax: [no] redistribution

Enabling learning of default routes

By default, the software does not learn RIP default routes.

To enable learning of default RIP routes, enter commands such as the following.

```
Brocade(config)#interface ethernet 0/1/1
Brocade(config-if-e1000-1)#ip rip learn-default
```

Syntax: [no] ip rip learn-default

Changing the route loop prevention method

RIP can use the following methods to prevent routing loops:

- Split horizon – The Brocade device does not advertise a route on the same interface as the one on which it learned the route.
- Poison reverse – The Brocade device assigns a cost of 16 (“infinite” or “unreachable”) to a route before advertising it on the same interface as the one on which it learned the route. This is the default.

NOTE

These methods are in addition to the RIP maximum valid route cost of 15.

To enable split horizon, enter commands such as the following.

```
Brocade(config)#interface ethernet 0/1/1
Brocade(config-if-e1000-1)#no ip rip poison-reverse
```

Syntax: [no] ip rip poison-reverse

Other Layer 3 protocols

For information about other IP configuration commands in the Layer 2 with base Layer 3 image that are not included in this chapter, refer to [Chapter 26, “IP Configuration”](#).

For information about enabling or disabling Layer 3 routing protocols, refer to [“Enabling or disabling routing protocols”](#) on page 1196.

Enabling or disabling routing protocols

This section describes how to enable or disable routing protocols. For complete configuration information about the routing protocols, refer to [“RIP overview”](#) on page 1199.

The full Layer 3 code supports the following protocols:

- BGP4
- DVMRP
- IGMP
- IP
- IP multicast (PIM-SM, PIM-DM)
- OSPF

- PIM
- RIPV1 and V2
- VRRP
- VRRP-E
- VSRP

IP routing is enabled by default on devices running Layer 3 code. All other protocols are disabled, so you must enable them to configure and use them.

To enable a protocol on a device running full Layer 3 code, enter **router** at the global CONFIG level, followed by the protocol to be enabled. The following example shows how to enable OSPF.

```
Brocade(config)#router ospf
```

Syntax: router bgp | dvmrp | igmp | ip | ospf | pim | rip | vrrp | vrrp-e | vsrp

Enabling or disabling Layer 2 switching

By default, Brocade Layer 3 switches support Layer 2 switching. These devices modify the routing protocols that are not supported on the devices. If you want to disable Layer 2 switching, you can do so globally or on individual ports, depending on the version of software your device is running.

NOTE

Consult your reseller or Brocade to understand the risks involved before disabling all Layer 2 switching operations.

Configuration notes and feature limitations for Layer 2 switching

- Enabling or disabling Layer 2 switching is supported in the edge Layer 3 and full Layer 3 software images only.
- FWS EPREM devices support disabling Layer 2 switching at the global CONFIG level only.
- FastIron X Series and Brocade FCX Series devices support disabling Layer 2 switching at the interface configuration level as well as the global CONFIG level.
- Enabling or disabling Layer 2 switching is not supported on virtual interfaces.

Command syntax for Layer 2 switching

To globally disable Layer 2 switching on a Layer 3 switch, enter commands such as the following.

```
Brocade(config)#route-only
Brocade(config)#exit
Brocade#write memory
Brocade#reload
```

To re-enable Layer 2 switching on a Layer 3 switch, enter the following commands.

Enabling or disabling Layer 2 switching

```
Brocade(config)#no route-only
Brocade(config)#exit
Brocade#write memory
Brocade#reload
```

Syntax: [no] route-only

To disable Layer 2 switching only on a specific interface, go to the interface configuration level for that interface, and then disable the feature. The following commands show how to disable Layer 2 switching on port 2.

```
Brocade(config)#interface ethernet 2
Brocade(config-if-e1000-2)#route-only
```

RIP (IPv4)

Table 204 lists the individual Brocade FastIron switches and the Routing Information Protocol (RIP) for IPv4 features they support. These features are supported in the edge Layer 3 and full Layer 3 software images.

TABLE 204 Supported RIP features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6450
RIP V1 and V2	Yes	Yes	Yes	Yes	Yes
Route learning and advertising	Yes	Yes	Yes	Yes	Yes
Route redistribution into RIP	Yes	Yes	Yes	Yes	Yes
Route metrics	Yes	Yes	Yes	Yes	Yes
Route loop prevention: <ul style="list-style-type: none"> • Poison reverse • Split horizon 	Yes	Yes	Yes	Yes	Yes
RIP route advertisement suppression on a VRRP or VRRP-E backup interface	Yes	Yes	Yes	Yes	Yes
Route filters	Yes	Yes	Yes	Yes	Yes
CPU utilization statistics for RIP	Yes	Yes	Yes	Yes	Yes

RIP overview

Routing Information Protocol (RIP) is an IP route exchange protocol that uses a *distance vector* (a number representing a distance) to measure the cost of a given route. The cost is a distance vector because the cost often is equivalent to the number of router hops between the Brocade Layer 3 Switch and the destination network.

A Brocade Layer 3 Switch can receive multiple paths to a destination. The software evaluates the paths, selects the best path, and saves the path in the IP route table as the route to the destination. Typically, the best path is the path with the fewest hops. A hop is another router through which packets must travel to reach the destination. If the Brocade Layer 3 Switch receives a RIP update from another router that contains a path with fewer hops than the path stored in the Brocade Layer 3 Switch route table, the Layer 3 Switch replaces the older route with the newer one. The Layer 3 Switch then includes the new path in the updates it sends to other RIP routers, including Brocade Layer 3 Switches.

RIP routers, including the Brocade Layer 3 Switch, also can modify a route cost, generally by adding to it, to bias the selection of a route for a given destination. In this case, the actual number of router hops may be the same, but the route has an administratively higher cost and is thus less likely to be used than other, lower-cost routes.

A RIP route can have a maximum cost of 15. Any destination with a higher cost is considered unreachable. Although limiting to larger networks, the low maximum hop count prevents endless loops in the network.

Brocade Layer 3 Switches support the following RIP versions:

- Version (V1)
- V1 compatible with V2
- Version (V2) (the default)

ICMP host unreachable message for undeliverable ARPs

If the router receives an ARP request packet that it is unable to deliver to the final destination because of the ARP timeout and no ARP response is received (the router knows of no route to the destination address), the router sends an ICMP Host Unreachable message to the source.

RIP parameters and defaults

The following tables list the RIP parameters, their default values, and where to find configuration information.

RIP global parameters

[Table 205](#) lists the global RIP parameters and their default values, and indicates where you can find configuration information.

TABLE 205 RIP global parameters

Parameter	Description	Default	Reference
RIP state	The global state of the protocol. NOTE: You also must enable the protocol on individual interfaces. Globally enabling the protocol does not allow interfaces to send and receive RIP information. Refer to Table 206 on page 1201.	Disabled	page 1202
Administrative distance	The administrative distance is a numeric value assigned to each type of route on the router. When the router is selecting from among multiple routes (sometimes of different origins) to the same destination, the router compares the administrative distances of the routes and selects the route with the lowest administrative distance. This parameter applies to routes originated by RIP. The administrative distance stays with a route when it is redistributed into other routing protocols.	120	page 1204
Redistribution	RIP can redistribute routes from other routing protocols such as OSPF and BGP4 into RIP. A redistributed route is one that a router learns through another protocol, then distributes into RIP.	Disabled	page 1205

TABLE 205 RIP global parameters (Continued)

Parameter	Description	Default	Reference
Redistribution metric	RIP assigns a RIP metric (cost) to each external route redistributed from another routing protocol into RIP. An external route is a route with at least one hop (packets must travel through at least one other router to reach the destination). This parameter applies to routes that are redistributed from other protocols into RIP.	1 (one)	page 1206
Update interval	How often the router sends route updates to its RIP neighbors.	30 seconds	page 1207
Learning default routes	The router can learn default routes from its RIP neighbors. NOTE: You also can enable or disable this parameter on an individual interface basis. Refer to Table 206 on page 1201.	Disabled	page 1207
Advertising and learning with specific neighbors	The Layer 3 Switch learns and advertises RIP routes with all its neighbors by default. You can prevent the Layer 3 Switch from advertising routes to specific neighbors or learning routes from specific neighbors.	Learning and advertising permitted for all neighbors	page 1208

RIP interface parameters

[Table 206](#) lists the interface-level RIP parameters and their default values, and indicates where you can find configuration information.

TABLE 206 RIP interface parameters

Parameter	Description	Default	Reference
RIP state and version	The state of the protocol and the version that is supported on the interface. The version can be one of the following: <ul style="list-style-type: none"> Version 1 only Version 2 only Version 1, but also compatible with version 2 NOTE: You also must enable RIP globally.	Disabled	page 1202
Metric	A numeric cost the router adds to RIP routes learned on the interface. This parameter applies only to RIP routes.	1 (one)	page 1203
Learning default routes	Locally overrides the global setting. Refer to Table 205 on page 1200.	Disabled	page 1207

TABLE 206 RIP interface parameters (Continued)

Parameter	Description	Default	Reference
Loop prevention	<p>The method a router uses to prevent routing loops caused by advertising a route on the same interface as the one on which the router learned the route.</p> <ul style="list-style-type: none"> Split horizon – The router does not advertise a route on the same interface as the one on which the router learned the route. Poison reverse – The router assigns a cost of 16 (“infinite” or “unreachable”) to a route before advertising it on the same interface as the one on which the router learned the route. 	<p>Poison reverse</p> <p>NOTE: Enabling split horizon disables poison reverse on the interface.</p>	page 1209
Advertising and learning specific routes	You can control the routes that a Layer 3 Switch learns or advertises.	The Layer 3 Switch learns and advertises all RIP routes on all interfaces.	page 1210

RIP parameter configuration

Use the following procedures to configure RIP parameters on a system-wide and individual interface basis.

Enabling RIP

RIP is disabled by default. To enable it, use the following procedure.

NOTE

You must enable the protocol globally and also on individual interfaces on which you want to advertise RIP. Globally enabling the protocol does not enable it on individual interfaces.

To enable RIP globally, enter the **router rip** command.

```
Brocade(config)#router rip
```

Syntax: [no] router rip

After globally enabling the protocol, you must enable it on individual interfaces. You can enable the protocol on physical interfaces as well as virtual routing interfaces. To enable RIP on an interface, enter commands such as the following.

```
Brocade(config)#interface ethernet 0/1/1
Brocade(config-if-0/1/1)#ip rip v1-only
```

Syntax: [no] ip rip v1-only | v1-compatible-v2 | v2-only

NOTE

You must specify the RIP version.

Enabling ECMP for routes in RIP

ECMP for routes in RIP is disabled by default. Use the **ecmp-enable** command to enable the feature at the router rip level.

```
Brocade(config-rip-router)#ecmp-enable
```

Syntax: [no] **ecmp-enable**

Configuring metric parameters

By default, a Brocade Layer 3 Switch port increases the cost of a RIP route that is learned on the port by one. You can configure individual ports to add more than one to a learned route cost. In addition, you can configure a RIP offset list to increase the metric for learned or advertised routes based on network address.

Changing the cost of routes learned on a port

By default, a Brocade Layer 3 Switch port increases the cost of a RIP route that is learned on the port. The Layer 3 Switch increases the cost by adding one to the route metric before storing the route.

You can change the amount that an individual port adds to the metric of RIP routes learned on the port. To do so, use the following method.

NOTE

RIP considers a route with a metric of 16 to be unreachable. Use this metric only if you do not want the route to be used. You can prevent the Layer 3 Switch from using a specific port for routes learned through that port by setting its metric to 16.

To increase the cost a port adds to RIP routes learned in that port, enter commands such as the following.

```
Brocade(config)#interface ethernet 0/6/1
Brocade(config-if-0/6/1)#ip metric 5
```

These commands configure port 6/1 to add 5 to the cost of each route learned on the port.

Syntax: **ip metric** <1-16>

Configuring a RIP offset list

A RIP offset list allows you to add to the metric of specific inbound or outbound routes learned or advertised by RIP. RIP offset lists provide a simple method for adding to the cost of specific routes and therefore biasing the Layer 3 Switch route selection away from those routes.

A RIP offset list consists of the following parameters:

- An access control list (ACL) that specifies the routes to which to add the metric.
- The direction:
 - In applies to routes the Layer 3 Switch learns from RIP neighbors.
 - Out applies to routes the Layer 3 Switch is advertising to its RIP neighbors.
- The type and number of a specific port to which the RIP offset list applies (optional).

The software adds the offset value to the routing metric (cost) of the routes that match the ACL. If a route matches both a global offset list and an interface-based offset list, the interface-based offset list takes precedence. The interface-based offset list metric is added to the route in this case.

You can configure up to 24 global RIP offset lists and up to 24 RIP offset lists on each interface.

To configure a global RIP offset list, enter commands such as the following.

```
Brocade(config)#access-list 21 deny 160.1.0.0 0.0.255.255
Brocade(config)#access-list 21 permit any
Brocade(config)#router rip
Brocade(config-rip-router)#offset-list 21 out 10
```

The commands in this example configure a standard ACL. The ACL matches on all IP networks except 160.1.x.x. When the Layer 3 Switch advertises a route that matches ACL 21, the offset list adds 10 to the route metric.

Syntax: `[no] offset-list <ACL-number-or-name> in | out <metric> [ethernet <port>]`

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

In the following example, the Layer 3 Switch uses ACL 21 to add 10 to the metric of routes received on Ethernet port 0/2/1.

```
Brocade(config-rip-router)#offset-list 21 in 10 ethernet 0/2/1
```

Changing the administrative distance

By default, the Layer 3 Switch assigns the default RIP administrative distance (120) to RIP routes. When comparing routes based on administrative distance, the Layer 3 Switch selects the route with the lower distance. You can change the administrative distance for RIP routes.

NOTE

Refer to [“Changing administrative distances”](#) on page 1374 for the default distances for all route sources.

To change the administrative distance for RIP routes, enter the **distance** command.

```
Brocade(config-rip-router)#distance 140
```

This command changes the administrative distance to 140 for all RIP routes.

Syntax: `[no] distance <num>`

The *<num>* variable specifies a range from 1 through 255.

Configuring redistribution

You can configure the Layer 3 Switch to redistribute routes learned through Open Shortest Path First (OSPF) or Border Gateway Protocol version 4 (BGP4) into RIP. When you redistribute a route from one of these other protocols into RIP, the Layer 3 Switch can use RIP to advertise the route to its RIP neighbors.

To configure redistribution, perform the following tasks:

1. Configure redistribution filters (optional). You can configure filters to permit or deny redistribution for a route based on its origin (OSPF, BGP4, and so on), the destination network address, and the route metric. You also can configure a filter to set the metric based on these criteria.
2. Change the default redistribution metric (optional). The Layer 3 Switch assigns a RIP metric of 1 to each redistributed route by default. You can change the default metric to a value up to 16.
3. Enable redistribution.

NOTE

Do not enable redistribution until you configure the other redistribution parameters.

Configuring redistribution filters

RIP redistribution filters apply to all interfaces. The software uses the filters in ascending numerical order and immediately takes the action specified by the filter. Thus, if filter 1 denies redistribution of a given route, the software does not redistribute the route, regardless of whether a filter with a higher ID would permit redistribution of that route.

NOTE

The default redistribution action is permit, even after you configure and apply redistribution filters to the virtual routing interface. If you want to tightly control redistribution, apply a filter to deny all routes as the last filter (the filter with the highest ID), and then apply filters with lower filter IDs to allow specific routes.

To configure a redistribution filter, enter a command such as the following.

```
Brocade(config-rip-router)#deny redistribute 2 all address 207.92.0.0 255.255.0.0
```

This command denies redistribution for all types of routes to the 207.92.x.x network.

Syntax: [no] permit | deny redistribute <filter-num> all | bgp | ospf | static address <ip-addr> <ip-mask> [match-metric <value> | set-metric <value>]

The <filter-num> variable specifies the redistribution filter ID. The software uses the filters in ascending numerical order. Thus, if filter 1 denies a route from being redistributed, the software does not redistribute that route even if a filter with a higher ID permits redistribution of the route.

The **all** parameter applies redistribution to all route types.

The **bgp** parameter applies redistribution to BGP4 routes only.

The **ospf** parameter applies redistribution to OSPF routes only.

The **static** parameter applies redistribution to IP static routes only.

The **address** *<ip-addr> <ip-mask>* parameters apply redistribution to the specified network and subnet address. Use 0 to specify “any”. For example, “207.92.0.0 255.255.0.0” means “any 207.92.x.x subnet”. However, to specify any subnet (all subnets match the filter), enter “address 255.255.255.255 255.255.255.255”.

The **match-metric** *<value>* parameter applies the redistribution filter only to those routes with the specified metric value; possible values are from 1 through 15.

The **set-metric** *<value>* parameter sets the RIP metric value that will be applied to those routes imported into RIP.

The following command denies redistribution into RIP for all OSPF routes.

```
Brocade(config-rip-router)#deny redistribute 3 ospf address 207.92.0.0
255.255.0.0
```

The following command denies redistribution for all OSPF routes that have a metric of 10.

```
Brocade(config-rip-router)#deny redistribute 3 ospf address 207.92.0.0
255.255.0.0 match-metric 10
```

The following commands deny redistribution of all routes except routes for 10.10.10.x and 20.20.20.x.

```
Brocade(config-rip-router)#deny redistribute 64 static address 255.255.255.255
255.255.255.255
Brocade(config-rip-router)#permit redistribute 1 static address 10.10.10.0
255.255.255.0
Brocade(config-rip-router)#permit redistribute 2 static address 20.20.20.0
255.255.255.0
```

NOTE

This example assumes that the highest RIP redistribution filter ID configured on the device is 64.

Changing the redistribution metric

When the Layer 3 Switch redistributes a route into RIP, the software assigns a RIP metric (cost) to the route. By default, the software assigns a metric of 1 to each route that is redistributed into RIP. You can increase the metric that the Layer 3 Switch assigns up to 15.

To change the RIP metric the Layer 3 Switch assigns to redistributed routes, enter a command such as the following.

```
Brocade(config-rip-router)#default-metric 10
```

This command assigns a RIP metric of 10 to each route that is redistributed into RIP.

Syntax: [no] default-metric *<1-15>*

Enabling redistribution

After you configure redistribution parameters, you need to enable redistribution.

To enable RIP redistribution, enter the **redistribution** command.

```
Brocade(config-rip-router)#redistribution
```

Syntax: [no] redistribution

The **no** form of this command disables RIP redistribution.

Removing a RIP redistribution deny filter

To remove a previously configured RIP redistribution deny filter, perform the following task:

1. Remove the RIP redistribution deny filter.
2. Disable the redistribution function.
3. Re-enable redistribution.

The following shows an example of how to remove a RIP redistribution deny filter.

```
Brocade(config-rip-router)#no deny redistribute 2 all address 207.92.0.0
255.255.0.0
Brocade(config-rip-router)#no redistribution
Brocade(config-rip-router)#redistribution
```

Route learning and advertising parameters

By default, a Brocade Layer 3 Switch learns routes from all its RIP neighbors and advertises RIP routes to those neighbors.

You can configure the following learning and advertising parameters:

- **Update interval** – The update interval specifies how often the Layer 3 Switch sends RIP route advertisements to its neighbors. You can change the interval to a value from 1 through 1000 seconds. The default is 30 seconds.
- **Learning and advertising of RIP default routes** – The Layer 3 Switch learns and advertises RIP default routes by default. You can disable learning and advertising of default routes on a global or individual interface basis.
- **Learning of standard RIP routes** – By default, the Layer 3 Switch learns RIP routes from all its RIP neighbors. You can configure RIP neighbor filters to explicitly permit or deny learning from specific neighbors.

Changing the update interval for route advertisements

The update interval specifies how often the Layer 3 Switch sends route advertisements to its RIP neighbors. You can specify an interval from 1 through 1000 seconds. The default is 30 seconds.

To change the RIP update interval, enter a command such as the following.

```
Brocade(config-rip-router)#update-time 120
```

This command configures the Layer 3 Switch to send RIP updates every 120 seconds.

Syntax: update-time <1-1000>

Enabling learning of RIP default routes

You can enable learning of RIP default routes on a global or individual interface basis.

To enable learning of default RIP routes on a global basis, enter the following command.

```
Brocade(config-rip-router)#learn-default
```

Syntax: [no] learn-default

To enable learning of default RIP routes on an individual interface basis, enter commands such as the following.

```
Brocade(config)#interface ethernet 0/1/1
Brocade(config-if-0/1/1)#ip rip learn-default
```

Syntax: [no] ip rip learn-default

Configuring a RIP neighbor filter

By default, a Brocade Layer 3 Switch learns RIP routes from all its RIP neighbors. Neighbor filters allow you to specify the neighbor routers from which the Brocade device can receive RIP routes. Neighbor filters apply globally to all ports.

To configure a RIP neighbor filter, enter a command such as the following.

```
Brocade(config-rip-router)#neighbor 1 deny any
```

This command configures the Layer 3 Switch so that the device does not learn any RIP routes from any RIP neighbors.

Syntax: [no] neighbor <filter-num> permit | deny <source-ip-address> | any

The following commands configure the Layer 3 Switch to learn routes from all neighbors except 192.168.1.170. Once you define a RIP neighbor filter, the default action changes from learning all routes from all neighbors to denying all routes from all neighbors except the ones you explicitly permit. To deny learning from a specific neighbor but allow all other neighbors, you must add a filter that allows learning from all neighbors. Be sure to add the filter to permit all neighbors last (the one with the highest filter number). Otherwise, the software can match on the permit all filter instead of a filter that denies a specific neighbor, and learn routes from that neighbor.

```
Brocade(config-rip-router)#neighbor 2 deny 192.16.1.170
Brocade(config-rip-router)#neighbor 1024 permit any
```

Denying route advertisements for connected routes

By default, RIP advertises all connected routes to neighboring routers except for the management route. To configure the router to not advertise connected routes, use the **dont-advertise-connected** command. When the **dont-advertise-connected** command is configured, the router only sends RIP enabled interface routes.

To configure the **dont-advertise-connected** command under the router RIP configuration level, enter the **router rip** command.

```
FastIron(config)#router rip
FastIron(config-rip-router)#dont-advertise-connected
```

Syntax: [no] dont-advertise-connected

To disable the configuration, use the **no** form of the command.

Changing the route loop prevention method

RIP can use the following methods to prevent routing loops:

- Split horizon – The Layer 3 Switch does not advertise a route on the same interface as the one on which the router learned the route.
- Poison reverse – The Layer 3 Switch assigns a cost of 16 (“infinite” or “unreachable”) to a route before advertising it on the same interface as the one on which the router learned the route. This is the default.

These loop prevention methods are configurable on an individual interface basis. One of the methods is always in effect on an interface enabled for RIP. If you disable one method, the other method is enabled.

NOTE

These methods may be used in addition to the RIP maximum valid route cost of 15.

Disabling poison-reverse

To disable poison reverse and enable split horizon on an interface, enter commands such as the following.

```
Brocade(config)#interface ethernet 0/1/1
Brocade(config-if-0/1/1)#no ip rip poison-reverse
```

Syntax: [no] ip rip poison-reverse

To disable split horizon and enable poison reverse on an interface, enter commands such as the following.

```
Brocade(config)#interface ethernet 0/1/1
Brocade(config-if-0/1/1)#ip rip poison-reverse
```

Suppressing RIP route advertisement on a VRRP or VRRP-E backup interface

NOTE

This section applies only if you configure the Layer 3 Switch for Virtual Router Redundancy Protocol (VRRP) or VRRP Extended (VRRP-E). Refer to [Chapter 39, “VRRP and VRRP-E”](#).

Normally, a VRRP or VRRP-E backup includes route information for the virtual IP address (the backed-up interface) in RIP advertisements. As a result, other routers receive multiple paths for the backed-up interface and might sometimes unsuccessfully use the path to the backup rather than the path to the master.

You can prevent the backups from advertising route information for the backed-up interface by enabling suppression of the advertisements.

To suppress RIP advertisements for the backed-up interface, enter the following commands.

```
Brocade(config)#router rip
Brocade(config-rip-router)#use-vrrp-path
```

Syntax: [no] use-vrrp-path

The syntax is the same for VRRP and VRRP-E.

Configuring RIP route filters

You can configure RIP route filters to permit or deny learning or advertising of specific routes. Configure the filters globally, then apply them to individual interfaces. When you apply a RIP route filter to an interface, you specify whether the filter applies to learned routes (in) or advertised routes (out).

NOTE

A route is defined by the destination IP address and network mask.

NOTE

By default, routes that do not match a route filter are learned or advertised. To prevent a route from being learned or advertised, you must configure a filter to deny the route.

To configure RIP filters, enter commands such as the following.

```
Brocade(config-rip-router)#filter 1 permit 192.53.4.1 255.255.255.0
Brocade(config-rip-router)#filter 2 permit 192.53.5.1 255.255.255.0
Brocade(config-rip-router)#filter 3 permit 192.53.6.1 255.255.255.0
Brocade(config-rip-router)#filter 4 deny 192.53.7.1 255.255.255.0
```

These commands explicitly permit RIP routes to three networks, and deny the route to one network.

Because the default action is permit, all other routes (routes not explicitly permitted or denied by the filters) can be learned or advertised.

Syntax: `filter <filter-num> permit | deny <source-ip-address> | any <source-mask> | any [log]`

Applying a RIP route filter to an interface

Once you define RIP route filters, you must assign them to individual interfaces. The filters do not take effect until you apply them to interfaces. When you apply a RIP route filter, you also specify whether the filter applies to learned routes or advertised routes:

- Out filters apply to routes the Layer 3 Switch advertises to its neighbor on the interface.
- In filters apply to routes the Layer 3 Switch learns from its neighbor on the interface.

To apply RIP route filters to an interface, enter commands such as the following.

```
Brocade(config)#interface ethernet 0/1/2
Brocade(config-if-0/1/2)#ip rip filter-group in 2 3 4
```

These commands apply RIP route filters 2, 3, and 4 to all routes learned from the RIP neighbor on port 1/2.

Syntax: `[no] ip rip filter-group in | out <filter-list>`

Displaying RIP filters

To display the RIP filters configured on the router, enter the **show ip rip** command at any CLI level.

```
Brocade#show ip rip
```

```

      RIP Route Filter Table
  Index  Action  Route IP Address  Subnet Mask
  1      deny   any               any

      RIP Neighbor Filter Table
  Index  Action  Neighbor IP Address
  1      permit any

```

Syntax: **show ip rip**

[Table 207](#) describes the information displayed by the **show ip rip** command.

TABLE 207 CLI display of RIP filter information

Field	Definition
Route filters	
The rows underneath “RIP Route Filter Table” list the RIP route filters. If no RIP route filters are configured on the device, the following message is displayed: “No Filters are configured in RIP Route Filter Table”.	
Index	The filter number. You assign this number when you configure the filter.
Action	<p>The action the router takes if a RIP route packet matches the IP address and subnet mask of the filter. The action can be one of the following:</p> <ul style="list-style-type: none"> deny – RIP route packets that match the address and network mask information in the filter are dropped. If applied to an interface outbound filter group, the filter prevents the router from advertising the route on that interface. If applied to an interface inbound filter group, the filter prevents the router from adding the route to its IP route table. permit – RIP route packets that match the address and network mask information are accepted. If applied to an interface outbound filter group, the filter allows the router to advertise the route on that interface. If applied to an interface inbound filter group, the filter allows the router to add the route to its IP route table.
Route IP Address	The IP address of the route destination network or host.
Subnet Mask	The network mask for the IP address.
Neighbor filters	
The rows underneath “RIP Neighbor Filter Table” list the RIP neighbor filters. If no RIP neighbor filters are configured on the device, the following message is displayed: “No Filters are configured in RIP Neighbor Filter Table”.	
Index	The filter number. You assign this number when you configure the filter.
Action	<p>The action the router takes for RIP route packets to or from the specified neighbor:</p> <ul style="list-style-type: none"> deny – If the filter is applied to an interface outbound filter group, the filter prevents the router from advertising RIP routes to the specified neighbor on that interface. If the filter is applied to an interface inbound filter group, the filter prevents the router from receiving RIP updates from the specified neighbor. permit – If the filter is applied to an interface outbound filter group, the filter allows the router to advertise RIP routes to the specified neighbor on that interface. If the filter is applied to an interface inbound filter group, the filter allows the router to receive RIP updates from the specified neighbor.
Neighbor IP Address	The IP address of the RIP neighbor.

Displaying CPU utilization statistics

You can display CPU utilization statistics for RIP and other IP protocols. To display CPU utilization statistics for RIP for the previous five-second, one-minute, five-minute, fifteen-minute, and runtime intervals, enter the **show process cpu** command at any level of the CLI.

```
Brocade#show process cpu
```

Process Name	5Sec(%)	1Min(%)	5Min(%)	15Min(%)	Runtime(ms)
ARP	0.01	0.03	0.09	0.22	9
BGP	0.04	0.06	0.08	0.14	13
GVRP	0.00	0.00	0.00	0.00	0
ICMP	0.00	0.00	0.00	0.00	0
IP	0.00	0.00	0.00	0.00	0
OSPF	0.00	0.00	0.00	0.00	0
RIP	0.04	0.07	0.08	0.09	7
STP	0.00	0.00	0.00	0.00	0
VRRP	0.00	0.00	0.00	0.00	0

If the software has been running less than 15 minutes (the maximum interval for utilization statistics), the command indicates how long the software has been running, as shown in the following example.

```
Brocade#show process cpu
```

The system has only been up for 6 seconds.

Process Name	5Sec(%)	1Min(%)	5Min(%)	15Min(%)	Runtime(ms)
ARP	0.01	0.00	0.00	0.00	0
BGP	0.00	0.00	0.00	0.00	0
GVRP	0.00	0.00	0.00	0.00	0
ICMP	0.01	0.00	0.00	0.00	1
IP	0.00	0.00	0.00	0.00	0
OSPF	0.00	0.00	0.00	0.00	0
RIP	0.00	0.00	0.00	0.00	0
STP	0.00	0.00	0.00	0.00	0
VRRP	0.00	0.00	0.00	0.00	0

To display utilization statistics for a specific number of seconds, enter a command such as the following.

```
Brocade#show process cpu 2
```

Statistics for last 1 sec and 80 ms

Process Name	Sec(%)	Time(ms)
ARP	0.00	0
BGP	0.00	0
GVRP	0.00	0
ICMP	0.01	1
IP	0.00	0
OSPF	0.00	0
RIP	0.00	0
STP	0.01	0
VRRP	0.00	0

When you specify how many seconds' worth of statistics you want to display, the software selects the sample that most closely matches the number of seconds you specified. In this example, statistics are requested for the previous two seconds. The closest sample available is for the previous 1 second and 80 milliseconds.

Syntax: `show process cpu [<num>]`

The `<num>` parameter specifies the number of seconds and can be from 1 through 900. If you use this parameter, the command lists the usage statistics only for the specified number of seconds. If you do not use this parameter, the command lists the usage statistics for the previous five-second, one-minute, five-minute, and fifteen-minute intervals.

Displaying CPU utilization statistics

RIP (IPv6)

Table 208 lists the individual Brocade FastIron switches and the Routing Information Protocol (RIP) for IPv6 features they support. These features are supported with premium IPv6 devices running the full Layer 3 software image

TABLE 208 Supported RIPng features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6450
RIPng	Yes	No	Yes	Yes	No
Up to 10K RIPng routes	Yes	No	No	No	No
RIPng timers	Yes	No	No	No	No
Route learning and advertising	Yes	No	No	No	No
Route redistribution into RIPng	Yes	No	No	No	No
Route loop prevention: <ul style="list-style-type: none"> • Poison reverse • Split horizon 	Yes	No	No	No	No
Clearing RIPng routes	Yes	No	No	No	No

RIPng overview

Routing Information Protocol (RIP) is an IP route exchange protocol that uses a distance vector (a number representing a distance) to measure the cost of a given route. RIP uses a hop count as its cost or metric.

IPv6 RIP, known as *Routing Information Protocol Next Generation* or RIPng functions similarly to IPv4 RIP Version 2. RIPng supports IPv6 addresses and prefixes and introduces some new commands that are specific to RIPng. This chapter describes the commands that are specific to RIPng. This section does not describe commands that apply to both IPv4 RIP and RIPng.

RIPng maintains a *Routing Information Base (RIB)*, which is a local route table. The local RIB contains the lowest-cost IPv6 routes learned from other RIP routers. In turn, RIPng attempts to add routes from its local RIB into the main IPv6 route table.

NOTE

Brocade IPv6 devices support up to 10,000 RIPng routes.

This section describes the following:

- How to configure RIPng
- How to clear RIPng information from the RIPng route table
- How to display RIPng information and statistics

Summary of configuration tasks

To configure RIPng, you must enable RIPng globally on the Brocade device and on individual router interfaces. The following configuration tasks are optional:

- Change the default settings of RIPng timers
- Configure how the Brocade device learns and advertises routes
- Configure which routes are redistributed into RIPng from other sources
- Configure how the Brocade device distributes routes through RIPng
- Configure poison reverse parameters

RIPng configuration

Before configuring the Brocade device to run RIPng, you must do the following:

- Enable the forwarding of IPv6 traffic on the Brocade device using the **ipv6 unicast-routing** command.
- Enable IPv6 on each interface on which you plan to enable RIPng. You enable IPv6 on an interface by configuring an IPv6 address or explicitly enabling IPv6 on that interface.

For more information about performing these configuration tasks, refer to the chapter [“IPv6 Configuration on FastIron X Series, FCX, and ICX Series Switches”](#) on page 353.

Enabling RIPng

By default, RIPng is disabled. To enable RIPng, you must enable it globally on the Brocade device and also on individual router interfaces.

NOTE

You are required to configure a router ID when running only IPv6 routing protocols.

NOTE

Enabling RIPng globally on the Brocade device does not enable it on individual router interfaces.

To enable RIPng globally, enter the following command.

```
Brocade(config)#ipv6 router rip
Brocade(config-ripng-router)#
```

After you enter this command, the Brocade device enters the RIPng configuration level, where you can access several commands that allow you to configure RIPng.

Syntax: `[no] ipv6 router rip`

To disable RIPng globally, use the **no** form of this command.

After enabling RIPng globally, you must enable it on individual router interfaces. You can enable it on physical as well as virtual routing interfaces. For example, to enable RIPng on Ethernet interface 3/1, enter the following commands.

```
Brocade(config)# interface ethernet 3/1
Brocade(config-if-e100-3/1)# ipv6 rip enable
```

Syntax: `[no] ipv6 rip enable`

To disable RIPng on an individual router interface, use the **no** form of this command.

RIPng timers

[Table 209](#) describes the RIPng timers and provides their defaults.

TABLE 209 RIPng timers

Timer	Description	Default
Update	Amount of time (in seconds) between RIPng routing updates.	30 seconds.
Timeout	Amount of time (in seconds) after which a route is considered unreachable.	180 seconds.
Hold-down	Amount of time (in seconds) during which information about other paths is ignored.	180 seconds.
Garbage-collection	Amount of time (in seconds) after which a route is removed from the routing table.	120 seconds.

You can adjust these timers for RIPng. Before doing so, keep the following caveats in mind:

- If you adjust these RIPng timers, Brocade strongly recommends setting the same timer values for all routers and access servers in the network.
- Setting the update timer to a shorter interval can cause the routers to spend excessive time updating the IPv6 route table.
- Brocade recommends setting the timeout timer value to at least three times the value of the update timer.
- Brocade recommends a shorter hold-down timer interval, because a longer interval can cause delays in RIPng convergence.

Updating RIPng timers

The following example sets updates to be broadcast every 45 seconds. If a route is not heard from in 135 seconds, the route is declared unusable. Further information is suppressed for an additional 10 seconds. Assuming no updates, the route is flushed from the routing table 20 seconds after the end of the hold-down period.

```
Brocade(config)# ipv6 router rip
Brocade(config-ripng-router)# timers 45 135 10 20
```

Syntax: `[no] timers <update-timer> <timeout-timer> <hold-down-timer> <garbage-collection-timer>`

Possible values for the timers are as follows

- Update timer: 3 through 65535 seconds
- Timeout timer: 9 through 65535 seconds
- Hold-down timer: 9 through 65535 seconds
- Garbage-collection timer: 9 through 65535 seconds

NOTE

You must enter a value for each timer, even if you want to retain the current setting of a particular timer.

To return to the default values of the RIPng timers, use the **no** form of this command.

Route learning and advertising parameters

You can configure the following learning and advertising parameters:

- Learning and advertising of RIPng default routes
- Advertising of IPv6 address summaries
- Metric of routes learned and advertised on a router interface

By default, the Brocade device does not learn IPv6 default routes (::/0). You can originate default routes into RIPng, which causes individual router interfaces to include the default routes in their updates. When configuring the origination of the default routes, you can also do the following:

- Suppress all other routes from the updates
- Include all other routes in the updates

Configuring default route learning and advertising

To originate default routes in RIPng and suppress all other routes in updates sent from Ethernet interface 3/1, enter the following commands.

```
Brocade(config)# interface ethernet 3/1
Brocade(config-if-e100-3/1)# ipv6 rip default-information only
```

To originate IPv6 default routes and include all other routes in updates sent from Ethernet interface 3/1, enter the following commands.

```
Brocade(config)# interface ethernet 3/1
Brocade(config-if-e100-3/1)# ipv6 rip default-information originate
```

Syntax: [no] **ipv6 rip default-information only | originate**

The **only** keyword originates the default routes and suppresses all other routes from the updates.

The **originate** keyword originates the default routes and includes all other routes in the updates.

To remove the explicit default routes from RIPng and suppress advertisement of these routes, use the **no** form of this command.

Advertising IPv6 address summaries

You can configure RIPng to advertise a summary of IPv6 addresses from a router interface and to specify an IPv6 prefix that summarizes the routes.

If a route prefix length matches the value specified in the **ipv6 rip summary-address** command, RIPng advertises the prefix specified in the **ipv6 rip summary-address** command instead of the original route.

For example, to advertise the summarized prefix 2001:DB8::/36 instead of the IPv6 address 2001:469e:0:adff:8935:e838:78:e0ff with a prefix length of 64 bits from Ethernet interface 3/1, enter the following commands.

```
Brocade(config)# interface ethernet 3/1
Brocade(config-if-e100-3/1)# ipv6 address 2001:db8:0:adff:8935:e838:78:
e0ff /64
Brocade(config-if-e100-3/1)# ipv6 rip summary-address 2001:db8::/36
```

Syntax: [no] **ipv6 rip summary-address** <ipv6-prefix>/<prefix-length>

You must specify the <ipv6-prefix> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

You must specify the <prefix-length> parameter as a decimal value. A slash mark (/) must follow the <ipv6-prefix> parameter and precede the <prefix-length> parameter.

To stop the advertising of the summarized IPv6 prefix, use the **no** form of this command.

Changing the metric of routes learned and advertised on an interface

A router interface increases the metric of an incoming RIPng route it learns by an offset (the default is 1). The Brocade device then places the route in the route table. When the Brocade device sends an update, it advertises the route with the metric plus the default offset of zero in an outgoing update message.

You can change the metric offset an individual interface adds to a route learned by the interface or advertised by the interface. For example, to change the metric offset for incoming routes learned by Ethernet interface 3/1 to 1 and the metric offset for outgoing routes advertised by the interface to 3, enter the following commands.

```
Brocade(config)#interface ethernet 3/1
Brocade(config-if-e100-3/1)#ipv6 rip metric-offset 1
Brocade(config-if-e100-3/1)#ipv6 rip metric-offset out 3
```

In this example, if Ethernet interface 3/1 learns about an incoming route, it will increase the incoming metric by 2 (the default offset of 1 and the additional offset of 1 as specified in this example). If Ethernet interface 3/1 advertises an outgoing route, it will increase the metric by 3 as specified in this example.

Syntax: [no] **ipv6 rip metric-offset** <1 - 16>

Syntax: [no] **ipv6 rip metric-offset out** <1 - 15>

To return the metric offset to its default value, use the **no** form of this command.

Redistributing routes into RIPng

You can configure the Brocade device to redistribute routes from the following sources into RIPng:

- IPv6 static routes
- Directly connected IPv6 networks
- OSPF V3

When you redistribute a route from IPv6 or OSPF V3 into RIPng, the Brocade device can use RIPng to advertise the route to its RIPng neighbors.

When configuring the Brocade device to redistribute routes, you can optionally specify a metric for the redistributed routes. If you do not explicitly configure a metric, the default metric value of 1 is used.

For example, to redistribute OSPF V3 routes into RIPng, enter the following commands.

```
Brocade(config)# ipv6 router rip
Brocade(config-ripng-router)# redistribute ospf
```

Syntax: `redistribute bgp | connected | isis | ospf | static [metric <number>]`

For the metric, specify a numerical value that is consistent with RIPng.

Controlling distribution of routes through RIPng

You can create a prefix list and then apply it to RIPng routing updates that are received or sent on a router interface. Performing this task allows you to control the distribution of routes through RIPng.

For example, to permit the inclusion of routes with the prefix 2001:DB8::/16 in RIPng routing updates sent from Ethernet interface 3/1, enter the following commands.

```
Brocade(config)# ipv6 prefix-list routesfor2001 permit 2001:db8::/16
Brocade(config)# ipv6 router rip
Brocade(config-ripng-router)# distribute-list prefix-list routesfor2001 out
ethernet 3/1
```

To deny prefix lengths greater than 64 bits in routes that have the prefix 3EE0:A99::/64 and allow all other routes received on tunnel interface 3/1, enter the following commands.

```
Brocade(config)# ipv6 prefix-list 3ee0routes deny 3ee0:a99::/64 le 128
Brocade(config)# ipv6 prefix-list 3ee0routes permit ::/0 ge 1 le 128
Brocade(config)# ipv6 router rip
Brocade(config-ripng-router)# distribute-list prefix-list 3ee0routes in
tunnel 1
```

Syntax: `[no] distribute-list prefix-list <name> in | out <interface> <port>`

The `<name>` parameter indicates the name of the prefix list generated using the `ipv6 prefix-list` command.

The `in` keyword indicates that the prefix list is applied to incoming routing updates on the specified interface.

The `out` keyword indicates that the prefix list is applied to outgoing routing updates on the specified interface.

For the *<interface>* parameter, you can specify the **ethernet**, **loopback**, **ve**, or **tunnel** keywords. If you specify an Ethernet interface, also specify the port number associated with the interface. If you specify a VE or tunnel interface, also specify the VE or tunnel number.

To remove the prefix list, use the **no** form of this command.

Configuring poison reverse parameters

By default, poison reverse is disabled on a RIPng router. If poison reverse is enabled, RIPng advertises routes it learns from a particular interface over that same interface with a metric of 16, which means that the route is unreachable.

If poison reverse is enabled on the RIPng router, it takes precedence over split horizon (if it is also enabled).

To enable poison reverse on the RIPng router, enter the following commands.

```
Brocade(config)# ipv6 router rip
Brocade(config-ripng-router)# poison-reverse
```

Syntax: [no] **poison-reverse**

To disable poison reverse, use the **no** form of this command.

By default, if a RIPng interface goes down, the Brocade device does not send a triggered update for the interface IPv6 networks.

To better handle this situation, you can configure a RIPng router to send a triggered update containing the local routes of the disabled interface with an unreachable metric of 16 to the other RIPng routers in the routing domain. You can enable the sending of a triggered update by entering the following commands.

```
Brocade(config)# ipv6 router rip
Brocade(config-ripng-router)# poison-local-routes
```

Syntax: [no] **poison-local-routes**

To disable the sending of a triggered update, use the **no** form of this command.

Clearing RIPng routes from the IPv6 route table

To clear all RIPng routes from the RIPng route table and the IPv6 main route table and reset the routes, enter the following command at the Privileged EXEC level or any of the CONFIG levels of the CLI.

```
Brocade# clear ipv6 rip routes
```

Syntax: **clear ipv6 rip routes**

Displaying the RIPng configuration

To display RIPng configuration information, enter the **show ipv6 rip** command at any CLI level.

```
Brocade# show ipv6 rip
IPv6 rip enabled, port 521
  Administrative distance is 120
  Updates every 30 seconds, expire after 180
  Holddown lasts 180 seconds, garbage collect after 120
  Split horizon is on; poison reverse is off
  Default routes are not generated
  Periodic updates 0, trigger updates 0
  Distribute List, Inbound : Not set
  Distribute List, Outbound : Not set
  Redistribute: CONNECTED
```

Syntax: **show ipv6 rip**

[Table 210](#) describes the information displayed by the **show ipv6 rip** command.

TABLE 210 RIPng configuration fields

Field	Description
IPv6 RIP status/port	The status of RIPng on the Brocade device. Possible status is “enabled” or “disabled.” The UDP port number over which RIPng is enabled.
Administrative distance	The setting of the administrative distance for RIPng.
Updates/expiration	The settings of the RIPng update and timeout timers.
Holddown/garbage collection	The settings of the RIPng hold-down and garbage-collection timers.
Split horizon/poison reverse	The status of the RIPng split horizon and poison reverse features. Possible status is “on” or “off.”
Default routes	The status of RIPng default routes.
Periodic updates/trigger updates	The number of periodic updates and triggered updates sent by the RIPng router.
Distribution lists	The inbound and outbound distribution lists applied to RIPng.
Redistribution	The types of IPv6 routes redistributed into RIPng. The types can include the following: <ul style="list-style-type: none"> • STATIC – IPv6 static routes are redistributed into RIPng. • CONNECTED – Directly connected IPv6 networks are redistributed into RIPng. • OSPF – OSPF V3 routes are redistributed into RIPng.

Displaying RIPng routing table

To display the RIPng routing table, enter the **show ipv6 rip route** command at any CLI level.

```
Brocade# show ipv6 rip route
IPv6 RIP Routing Table - 4 entries:
 2001::/64, from fe80::212:f2ff:fe87:9a40, ve 177      (314)
     RIP, metric 2, tag 0, timers: aging 11
 2001:11:11::/64, from ::, null      (0)
     CONNECTED, metric 1, tag 0, timers: none
 2001:aa:2001:102:1:1::/96, from ::, ve 102      (1)
     LOCAL, metric 1, tag 0, timers: none
 2001:aa:2061:31:1:1::/96, from fe80::2e0:52ff:fe88:8000, ve 100      (58)
     RIP, metric 2, tag 0, timers: aging 43
```

Syntax: **show ipv6 rip route** [*<ipv6-prefix>/<prefix-length>* | *<ipv6-address>*]

The *<ipv6-prefix>/<prefix-length>* parameters restrict the display to the entries for the specified IPv6 prefix. You must specify the *<ipv6-prefix>* parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the *<prefix-length>* parameter as a decimal value. A slash mark (/) must follow the *<ipv6-prefix>* parameter and precede the *<prefix-length>* parameter.

The *<ipv6-address>* parameter restricts the display to the entries for the specified IPv6 address. You must specify this parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

[Table 211](#) describes the information displayed by the **show ipv6 rip route** command.

TABLE 211 RIPng routing table fields

Field	Description
IPv6 RIPng Routing Table entries	The total number of entries in the RIPng routing table.
<i><ipv6-prefix>/<prefix-length></i> OR <i><ipv6-address></i>	The IPv6 prefix and prefix length. The IPv6 address.
Next-hop router	The next-hop router for this Brocade device. If :: appears, the route is originated locally.
Interface	The interface name. If "null" appears, the interface is originated locally.
Serial number	The number identifying the order in which the route was added to the RIPng route table.
Source of route	The source of the route information. The source can be one of the following: <ul style="list-style-type: none"> • LOCAL – Routes configured on local interfaces taking part in RIPng. • RIP – Routes learned by RIPng. • CONNECTED – IPv6 routes redistributed from directly connected networks. • STATIC – IPv6 static routes are redistributed into RIPng. • OSPF – OSPF V3 routes are redistributed into RIPng.
Metric <i><number></i>	The cost of the route. The <i><number></i> parameter indicates the number of hops to the destination.
Tag <i><number></i>	The tag value of the route.
Timers:	Indicates if the hold-down timer or the garbage-collection timer is set.

Displaying RIPvng routing table

OSPF version 2 (IPv4)

[Table 212](#) lists the individual Brocade FastIron switches and the Open Shortest Path First (OSPF) Version 2 (IPv4) features they support. These features are supported in the edge Layer 3 and full Layer 3 software images only.

TABLE 212 Supported OSPF V2 features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6450
OSPF V2	Yes	Yes	Yes	Yes	Yes
OSPF point-to-point links	Yes	Yes	Yes	Yes	Yes
RFC 1583 and RFC 2178 compliant	Yes	Yes	Yes	Yes	Yes
Support for OSPF RFC 2328 Appendix E	Yes	Yes	Yes	Yes	Yes
Dynamic OSPF activation and configuration	Yes	Yes	Yes	Yes	Yes
Dynamic OSPFmemory	Yes	Yes	Yes	Yes	Yes
OSPF graceful restart	Yes (FSX 800 and FSX 1600 only)	No	Yes (FCX stack only)	Yes (ICX 6610 stack only)	Yes (ICX 6450 stack only)
Assigning OSPF V2 areas	Yes	Yes	Yes	Yes	Yes
Assigning interfaces to an area	Yes	Yes	Yes	Yes	Yes
Timer for OSPF authentication changes	Yes	Yes	Yes	Yes	Yes
Block flooding of outbound LSAs on specific interfaces	Yes	Yes	Yes	Yes	Yes
OSPF non-broadcast interface	Yes	Yes	Yes	Yes	Yes
Virtual links	Yes	Yes	Yes	Yes	Yes
Changing the reference bandwidth for the cost on OSPF interfaces	Yes	Yes	Yes	Yes	Yes
Route redistribution filters	Yes	Yes	Yes	Yes	Yes
Prevent specific OSPF routes from being installed in the IP route table	Yes	Yes	Yes	Yes	Yes
Load sharing	Yes	Yes	Yes	Yes	Yes
Configuring default route origination	Yes	Yes	Yes	Yes	Yes
SPF timers	Yes	Yes	Yes	Yes	Yes
Modifying redistribution metric type	Yes	Yes	Yes	Yes	Yes
Modifying administrative distance	Yes	Yes	Yes	Yes	Yes
OSPF group LSA pacing	Yes	Yes	Yes	Yes	Yes

TABLE 212 Supported OSPF V2 features (Continued)

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6450
OSPF traps	Yes	Yes	Yes	Yes	Yes
Exit overflow interval	Yes	Yes	Yes	Yes	Yes
Syslog messages	Yes	Yes	Yes	Yes	Yes
Clearing OSPF information	Yes	Yes	Yes	Yes	Yes

This chapter describes how to configure OSPF Version 2 on Brocade Layer 3 Switches using the CLI. OSPF Version 2 is supported on devices running IPv4.

NOTE

The terms *Layer 3 Switch* and *router* are used interchangeably in this chapter and mean the same thing.

OSPF overview

Open Shortest Path First (OSPF) is a link-state routing protocol. The protocol uses link-state advertisements (LSAs) to update neighboring routers regarding its interfaces and information on those interfaces. The router floods these LSAs to all neighboring routers to update them regarding the interfaces. Each router maintains an identical database that describes its area topology to help a router determine the shortest path between it and any neighboring router.

Brocade Layer 3 Switches support the following types of LSAs, which are described in RFC 1583:

- Router link
- Network link
- Summary link
- Autonomous system (AS) summary link
- AS external link
- Not-So-Stubby Area (NSSA) external link
- Grace LSAs

OSPF is built upon a hierarchy of network components. The highest level of the hierarchy is the Autonomous System (AS). An autonomous system is defined as a number of networks, all of which share the same routing and administration characteristics.

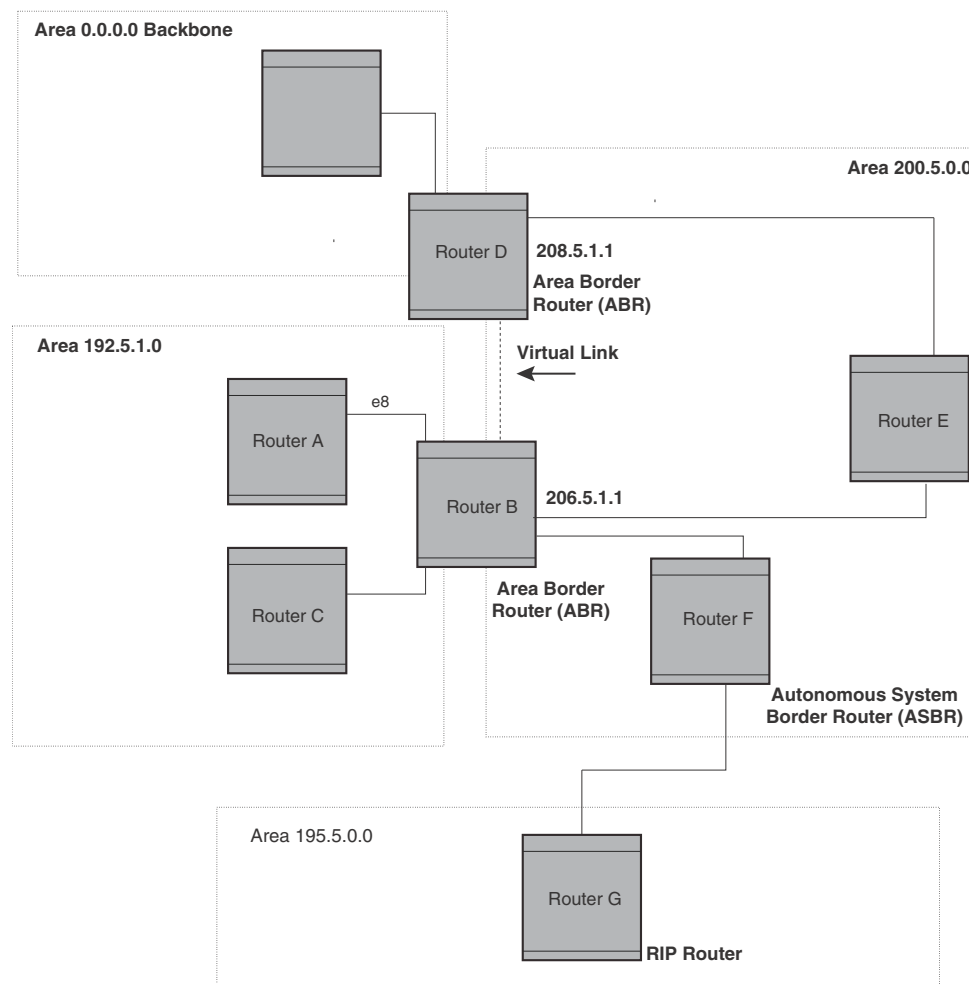

An AS can be divided into multiple areas as shown in [Figure 158](#) on page 1227. Each area represents a collection of contiguous networks and hosts. Areas limit the area to which link-state advertisements are broadcast, thereby limiting the amount of flooding that occurs within the network. An area is represented in OSPF by either an IP address or a number.

You can further limit the broadcast area of flooding by defining an area range. The area range allows you to assign an aggregate value to a range of IP addresses. This aggregate value becomes the address that is advertised instead all of the individual addresses it represents being advertised. You can assign up to 32 ranges in an OSPF area.

An OSPF router can be a member of multiple areas. Routers with membership in multiple areas are known as Area Border Routers (ABRs). Each ABR maintains a separate topological database for each area the router is in. Each topological database contains all of the LSA databases for each router within a given area. The routers within the same area have identical topological databases. The ABR is responsible for forwarding routing information or changes between its border areas.

An Autonomous System Boundary Router (ASBR) is a router that is running multiple protocols and serves as a gateway to routers outside an area and those operating with different protocols. The ASBR is able to import and translate different protocol routes into OSPF through a process known as *redistribution*. For more details on redistribution and configuration examples, refer to [“Enabling route redistribution”](#) on page 1258.

FIGURE 158 OSPF operating in a network

OSPF point-to-point links

One important OSPF process is **Adjacency**. Adjacency occurs when a relationship is formed between neighboring routers for the purpose of exchanging routing information. Adjacent OSPF neighbor routers go beyond the simple Hello packet exchange; they exchange database information. In order to minimize the amount of information exchanged on a particular segment, one of the first steps in creating adjacency is to assign a Designated Router (DR) and a Backup Designated Router (BDR). The Designated Router ensures that there is a central point of contact, thereby improving convergence time within a multi-access segment.

In an OSPF point-to-point network, where a direct Layer 3 connection exists between a single pair of OSPF routers, there is no need for Designated and Backup Designated Routers, as is the case in OSPF multi-access networks. Without the need for Designated and Backup Designated routers, a point-to-point network establishes adjacency and converges faster. The neighboring routers become adjacent whenever they can communicate directly. In contrast, in broadcast and non-broadcast multi-access (NBMA) networks, the Designated Router and Backup Designated Router become adjacent to all other routers attached to the network.

To configure an OSPF point-to-point link, refer to [“Configuring an OSPF point-to-point link”](#) on page 1269.

Designated routers in multi-access networks

In a network that has multiple routers attached, OSPF elects one router to serve as the designated router (DR) and another router on the segment to act as the backup designated router (BDR). This arrangement minimizes the amount of repetitive information that is forwarded on the network by forwarding all messages to the designated router and backup designated routers responsible for forwarding the updates throughout the network.

Designated router election in multi-access networks

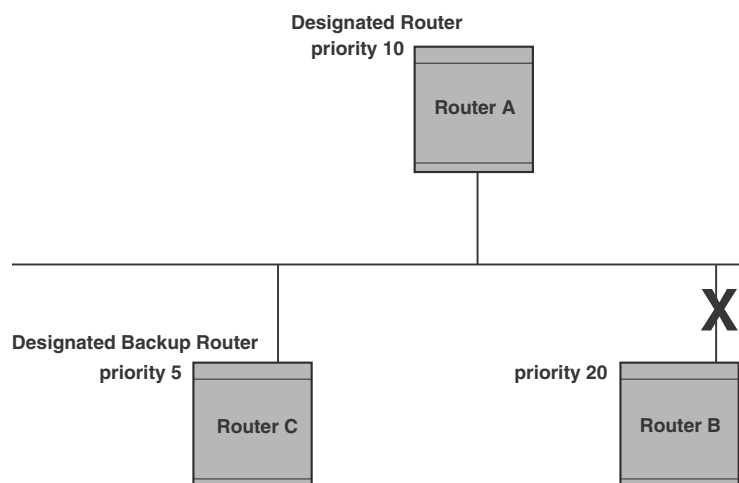

In a network with no designated router and no backup designated router, the neighboring router with the highest priority is elected as the DR, and the router with the next largest priority is elected as the BDR, as shown in [Figure 159](#)

FIGURE 159 Designated and backup router election

If the DR goes off-line, the BDR automatically becomes the DR. The router with the next highest priority becomes the new BDR. This process is shown in [Figure 160](#).

NOTE

Priority is a configurable option at the interface level. You can use this parameter to help bias one router as the DR.

FIGURE 160 Backup designated router becomes designated router

If two neighbors share the same priority, the router with the highest router ID is designated as the DR. The router with the next highest router ID is designated as the BDR.

NOTE

By default, the Brocade router ID is the IP address configured on the lowest numbered loopback interface. If the Layer 3 Switch does not have a loopback interface, the default router ID is the lowest numbered IP address configured on the device. For more information or to change the router ID, refer to [“Changing the router ID”](#) on page 976.

When multiple routers on the same network are declaring themselves as DRs, then both priority and router ID are used to select the designated router and backup designated routers.

When only one router on the network claims the DR role despite neighboring routers with higher priorities or router IDs, this router remains the DR. This is also true for BDRs.

The DR and BDR election process is performed when one of the following events occurs:

- An interface is in a waiting state and the wait time expires
- An interface is in a waiting state and a hello packet is received that addresses the BDR
- A change in the neighbor state occurs, such as:
 - A neighbor state transitions from 2 or higher
 - Communication to a neighbor is lost
 - A neighbor declares itself to be the DR or BDR for the first time

OSPF RFC 1583 and 2178 compliance

Brocade routers are configured, by default, to be compliant with the RFC 1583 OSPF V2 specification. Brocade routers can also be configured to operate with the latest OSPF standard, RFC 2178.

NOTE

For details on how to configure the system to operate with the RFC 2178, refer to [“Modifying the OSPF standard compliance setting”](#) on page 1268.

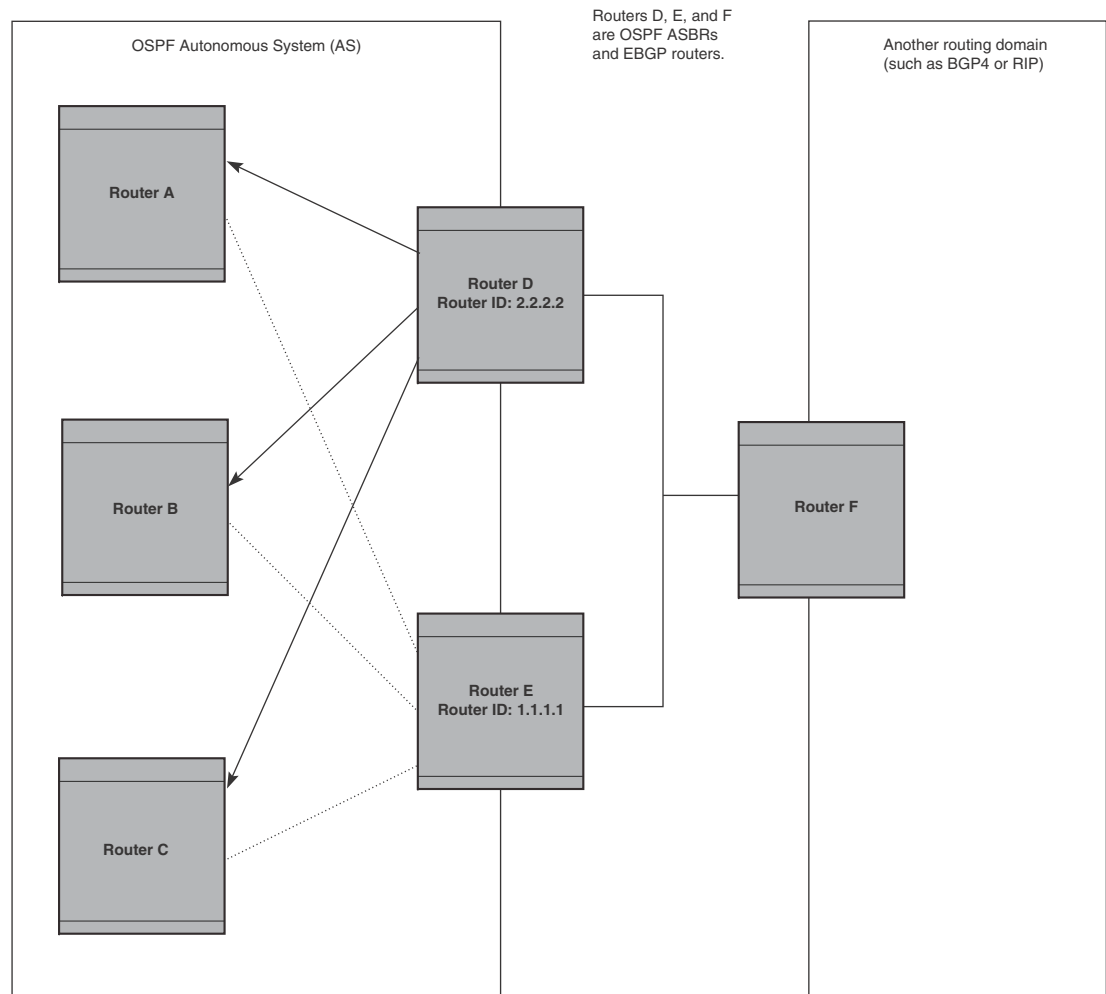

Reduction of equivalent AS External LSAs

An OSPF ASBR uses AS External link advertisements (AS External LSAs) to originate advertisements of a route to another routing domain, such as a BGP4 or RIP domain. The ASBR advertises the route to the external domain by flooding AS External LSAs to all the other OSPF routers (except those inside stub networks) within the local OSPF Autonomous System (AS).

In some cases, multiple ASBRs in an AS can originate equivalent LSAs. The LSAs are equivalent when they have the same cost, the same next hop, and the same destination. Brocade devices optimize OSPF by eliminating duplicate AS External LSAs in this case. The Layer 3 Switch with the lower router ID flushes the duplicate External LSAs from its database and thus does not flood the duplicate External LSAs into the OSPF AS. AS External LSA reduction therefore reduces the size of the Layer 3 Switch link state database.

This enhancement implements the portion of RFC 2328 that describes AS External LSA reduction. This enhancement is enabled by default, requires no configuration, and cannot be disabled.

[Figure 161](#) shows an example of the AS External LSA reduction feature. In this example, Brocade Layer 3 Switches D and E are OSPF ASBRs, and thus communicate route information between the OSPF AS, which contains Routers A, B, and C, and another routing domain, which contains Router F. The other routing domain is running another routing protocol, such as BGP4 or RIP. Routers D, E, and F, therefore, are each running both OSPF and either BGP4 or RIP.

FIGURE 161 AS External LSA reduction

Notice that both Router D and Router E have a route to the other routing domain through Router F. In earlier software releases, if Routers D and E have equal-cost routes to Router F, then both Router D and Router E flood AS External LSAs to Routers A, B, and C advertising the route to Router F. Since both routers are flooding equivalent routes, Routers A, B, and C receive multiple routes with the same cost to the same destination (Router F). For Routers A, B, and C, either route to Router F (through Router D or through Router E) is equally good.

OSPF eliminates the duplicate AS External LSAs. When two or more Brocade Layer 3 Switches configured as ASBRs have equal-cost routes to the same next-hop router in an external routing domain, the ASBR with the highest router ID floods the AS External LSAs for the external domain into the OSPF AS, while the other ASBRs flush the equivalent AS External LSAs from their databases. As a result, the overall volume of route advertisement traffic within the AS is reduced and the Layer 3 Switches that flush the duplicate AS External LSAs have more memory for other OSPF data. In [Figure 161](#), since Router D has a higher router ID than Router E, Router D floods the AS External LSAs for Router F to Routers A, B, and C. Router E flushes the equivalent AS External LSAs from its database.

Algorithm for AS External LSA reduction

Figure 161 shows an example in which the normal AS External LSA reduction feature is in effect. The behavior changes under the following conditions:

- There is one ASBR advertising (originating) a route to the external destination, but one of the following happens:
 - A second ASBR comes on-line
 - A second ASBR that is already on-line begins advertising an equivalent route to the same destination.

In either case above, the router with the higher router ID floods the AS External LSAs and the other router flushes its equivalent AS External LSAs. For example, if Router D is offline, Router E is the only source for a route to the external routing domain. When Router D comes on-line, it takes over flooding of the AS External LSAs to Router F, while Router E flushes its equivalent AS External LSAs to Router F.

- One of the ASBRs starts advertising a route that is no longer equivalent to the route the other ASBR is advertising. In this case, the ASBRs each flood AS External LSAs. Since the LSAs either no longer have the same cost or no longer have the same next-hop router, the LSAs are no longer equivalent, and the LSA reduction feature no longer applies.
- The ASBR with the higher router ID becomes unavailable or is reconfigured so that it is no longer an ASBR. In this case, the other ASBR floods the AS External LSAs. For example, if Router D goes off-line, then Router E starts flooding the AS with AS External LSAs for the route to Router F.

Support for OSPF RFC 2328 Appendix E

Brocade devices provide support for Appendix E in OSPF RFC 2328. Appendix E describes a method to ensure that an OSPF router (such as a Brocade Layer 3 Switch) generates unique link state IDs for type-5 (External) link state advertisements (LSAs) in cases where two networks have the same network address but different network masks.

NOTE

Support for Appendix E of RFC 2328 is enabled automatically and cannot be disabled. No user configuration is required.

Normally, an OSPF router uses the network address alone for the link state ID of the link state advertisement (LSA) for the network. For example, if the router needs to generate an LSA for network 10.1.2.3 255.0.0.0, the router generates ID 10.1.2.3 for the LSA.

However, suppose that an OSPF router needs to generate LSAs for all the following networks:

- 10.0.0.0 255.0.0.0
- 10.0.0.0 255.255.0.0
- 10.0.0.0 255.255.255.0

All three networks have the same network address, 10.0.0.0. Without support for RFC 2328 Appendix E, an OSPF router uses the same link state ID, 10.0.0.0, for the LSAs for all three networks. For example, if the router generates an LSA with ID 10.0.0.0 for network 10.0.0.0 255.0.0.0, this LSA conflicts with the LSA generated for network 10.0.0.0 255.255.0.0 or 10.0.0.0 255.255.255.0. The result is multiple LSAs that have the same ID but that contain different route information.

When Appendix E is supported, the router generates the link state ID for a network as follows.

1. Does an LSA with the network address as its ID already exist?
 - No – Use the network address as the ID.
 - Yes – Go to [step 2](#).
2. Compare the networks that have the same network address, to determine which network is more specific. The more specific network is the one that has more contiguous one bits in its network mask. For example, network 10.0.0.0 255.255.0.0 is more specific than network 10.0.0.0 255.0.0.0, because the first network has 16 ones bits (255.255.0.0) whereas the second network has only 8 ones bits (255.0.0.0):
 - For the less specific network, use the networks address as the ID.
 - For the more specific network, use the network broadcast address as the ID. The broadcast address is the network address, with all ones bits in the host portion of the address. For example, the broadcast address for network 10.0.0.0 255.255.0.0 is 10.0.255.255.

If this comparison results in a change to the ID of an LSA that has already been generated, the router generates a new LSA to replace the previous one. For example, if the router has already generated an LSA for network with ID 10.0.0.0 for network 10.0.0.0 255.255.255.0, the router must generate a new LSA for the network, if the router needs to generate an LSA for network 10.0.0.0 255.255.0.0 or 10.0.0.0 255.0.0.0.

Dynamic OSPF activation and configuration

OSPF is automatically activated when you enable it. The protocol does not require a software reload.

You can configure and save the following OSPF changes without resetting the system:

- All OSPF interface-related parameters (for example: area, hello timer, router dead time cost, priority, re-transmission time, transit delay)
- All area parameters
- All area range parameters
- All virtual-link parameters
- All global parameters
- Creation and deletion of an area, interface or virtual link

In addition, you can make the following changes without a system reset by first disabling and then re-enabling OSPF operation:

- Changes to address ranges
- Changes to global values for redistribution
- Addition of new virtual links

You also can change the amount of memory allocated to various types of LSA entries. However, these changes require a system reset or reboot.

Dynamic OSPF memory

FastIron devices dynamically allocate memory for Link State Advertisements (LSAs) and other OSPF data structures. This eliminates overflow conditions and does not require a reload to change OSPF memory allocation. So long as the Layer 3 Switch has free (unallocated) dynamic memory, OSPF can use the memory.

To display the current allocations of dynamic memory, use the **show memory** command.

OSPF graceful restart

OSPF graceful restart is a high-availability routing feature that minimizes disruption in traffic forwarding, diminishes route flapping, and provides continuous service during a system restart, including restart events that occur during a switchover, failover, or hitless OS upgrade. During such events, routes remain available between devices.

When OSPF graceful restart is enabled, a restarting router sends special LSAs, called grace LSAs, to its neighbors either before a planned OSPF restart or immediately after an unplanned restart. The grace LSAs specify a grace period for neighbors of the restarting router to continue using the existing routes to and through the router after a restart. When the restarting router comes back up, it continues to use its existing OSPF routes as if nothing happened. In the background, the router relearns its neighbors prior to the restart, recalculates its OSPF routes, and replaces existing routes with new routes as necessary. Once the grace period has passed, adjacent routers resume normal operation.

OSPF graceful restart is enabled globally by default. In this configuration, all OSPF neighbors are subject to the graceful restart capability. Neighbor routers must support the helper mode of OSPF graceful restart, which is enabled by default on all FastIron Layer 3 switches.

NOTE

OSPF graceful restart is supported in FSX 800 and FSX 1600 devices with dual management modules. If the device will function as a restart helper device only, a secondary management module is not required.

NOTE

If a FastIron device is configured for OSPF graceful restart and is intended to be used in switchover or hitless upgrade, the OSPF dead-interval should be changed to 60 seconds on OSPF interfaces to ensure that the graceful restart process succeeds without a timeout. Instructions for changing the OSPF dead-interval are provided in [“Modifying interface defaults”](#) on page 1242.

The Brocade implementation of OSPF graceful restart supports RFC 3623: Graceful OSPF Restart.

For details on how to configure OSPF graceful restart, refer to [“Configuring OSPF graceful restart”](#) on page 1269.

Configuring OSPF

Perform the following steps to begin using OSPF on the router.

1. [“Enabling OSPF on the router”](#) on page 1236
2. [“Assigning OSPF areas”](#) on page 1237
3. [“Assigning an area range \(optional\)”](#) on page 1241
4. [“Assigning interfaces to an area”](#) on page 1242.
5. [“Defining redistribution filters”](#) on page 1252
6. [“Enabling route redistribution”](#) on page 1258.
7. [“Modifying the OSPF standard compliance setting”](#) on page 1268

NOTE

OSPF is automatically enabled without a system reset.

OSPF configuration rules

- Brocade FastIron devices support a maximum of 676 OSPF interfaces.
- If a router is to operate as an ASBR, you must enable the ASBR capability at the system level.
- Redistribution must be enabled on routers configured to operate as ASBRs.
- All router ports must be assigned to one of the defined areas on an OSPF router. When a port is assigned to an area, all corresponding subnets on that port are automatically included in the assignment.

OSPF parameters

You can modify or set the following global and interface OSPF parameters.

Global parameters:

- Modify the OSPF standard compliance setting
- Assign OSPF areas
- Define an area range
- Define the area virtual link
- Set global default metric for OSPF
- Change the reference bandwidth for the default cost of OSPF interfaces
- Disable or re-enable load sharing
- Enable or disable default-information-originate
- Modify Shortest Path First (SPF) timers
- Define external route summarization
- Modify the redistribution metric type
- Define deny redistribution
- Define permit redistribution

- Enable redistribution
- Change the LSA pacing interval
- Modify OSPF Traps generated
- Modify database overflow interval

Interface parameters:

- Assign interfaces to an area
- Define the authentication key for the interface
- Change the authentication-change interval
- Modify the cost for a link
- Modify the dead interval
- Modify MD5 authentication key parameters
- Modify the priority of the interface
- Modify the retransmit interval for the interface
- Modify the transit delay of the interface

NOTE

When using the CLI, you set global level parameters at the OSPF CONFIG level of the CLI. To reach that level, enter **router ospf...** at the global CONFIG level. Interface parameters for OSPF are set at the interface CONFIG level using the CLI command, **ip ospf...**

When using the Web Management Interface, you set OSPF global parameters using the OSPF configuration panel. All other parameters are accessed through links accessed from the OSPF configuration sheet.

Enabling OSPF on the router

When you enable OSPF on the router, the protocol is automatically activated. To enable OSPF on the router, enter the following CLI command.

```
Brocade(config)#router ospf
```

This command launches you into the OSPF router level where you can assign areas and modify OSPF global parameters.

Syntax: **router ospf**

Note regarding disabling OSPF

If you disable OSPF, the Layer 3 Switch removes all the configuration information for the disabled protocol from the running-config. Moreover, when you save the configuration to the startup-config file after disabling one of these protocols, all the configuration information for the disabled protocol is removed from the startup-config file.

NOTE

If you do not want to delete the OSPF configuration information, use the CLI command **clear ip ospf all** instead of **no router ospf**. Refer to [“Resetting OSPF”](#) on page 1237.

When you enter the **no router ospf** command, the CLI displays a warning message such as the following.

```
Brocade(config-ospf-router)#no router ospf
router ospf mode now disabled. All ospf config data will be lost when writing to
flash!
```

The Web Management Interface does not display a warning message.

If you have disabled the protocol but have not yet saved the configuration to the startup-config file and reloaded the software, you can restore the configuration information by re-entering the command to enable the protocol (for example, **router ospf**), or by selecting the Web management option to enable the protocol. If you have already saved the configuration to the startup-config file and reloaded the software, the information is gone.

If you are testing an OSPF configuration and are likely to disable and re-enable the protocol, you might want to make a backup copy of the startup-config file containing the protocol configuration information. This way, if you remove the configuration information by saving the configuration after disabling the protocol, you can restore the configuration by copying the backup copy of the startup-config file onto the flash memory.

Resetting OSPF

The **clear ip ospf all** command globally resets (disables then re-enables) OSPF without deleting the OSPF configuration information. This command is equivalent to entering the commands **no router ospf** followed by **router ospf**. Whereas the **no router ospf** command disables OSPF and removes all the configuration information for the disabled protocol from the running-config, the **router ospf** command re-enables OSPF and restores the OSPF configuration information.

The **clear ip ospf all** command is useful if you are testing an OSPF configuration and are likely to disable and re-enable the protocol. This way, you do not have to save the configuration after disabling the protocol, and you do not have to restore the configuration by copying the backup copy of the startup-config file onto the flash memory.

To reset OSPF without deleting the OSPF configuration, enter the following command at the Global CONFIG level or at the Router OSPF level of the CLI.

```
Brocade#clear ip ospf all
```

Syntax: **clear ip ospf all**

Assigning OSPF areas

Once OSPF is enabled on the system, you can assign areas. Assign an IP address or number as the area ID for each area. The area ID is representative of all IP addresses (subnets) on a router port. Each port on a router can support one area.

An area can be normal, a stub, or a Not-So-Stubby Area (NSSA):

- Normal – OSPF routers within a normal area can send and receive External Link State Advertisements (LSAs).
- Stub – OSPF routers within a stub area cannot send or receive External LSAs. In addition, OSPF routers in a stub area must use a default route to the area Area Border Router (ABR) or Autonomous System Boundary Router (ASBR) to send traffic out of the area.

- NSSA – The ASBR of an NSSA can import external route information into the area:
 - ASBRs redistribute (import) external routes into the NSSA as type 7 LSAs. Type-7 External LSAs are a special type of LSA generated only by ASBRs within an NSSA, and are flooded to all the routers within only that NSSA.
 - ABRs translate type 7 LSAs into type 5 External LSAs, which can then be flooded throughout the AS. You can configure address ranges on the ABR of an NSSA so that the ABR converts multiple type-7 External LSAs received from the NSSA into a single type-5 External LSA.

When an NSSA contains more than one ABR, OSPF elects one of the ABRs to perform the LSA translation for NSSA. OSPF elects the ABR with the highest router ID. If the elected ABR becomes unavailable, OSPF automatically elects the ABR with the next highest router ID to take over translation of LSAs for the NSSA. The election process for NSSA ABRs is automatic.

Example

To set up the OSPF areas shown in [Figure 158](#) on page 1227, enter the following commands.

```
Brocade(config-ospf-router)#area 192.5.1.0
Brocade(config-ospf-router)#area 200.5.0.0
Brocade(config-ospf-router)#area 195.5.0.0
Brocade(config-ospf-router)#area 0.0.0.0
Brocade(config-ospf-router)#write memory
```

Syntax: `area <num> | <ip-addr>`

The `<num> | <ip-addr>` parameter specifies the area number, which can be a number or in IP address format. If you specify a number, the number can be from 0 through 18.

NOTE

You can assign one area on a router interface. For example, if the system or chassis module has 16 ports, 16 areas are supported on the chassis or module.

Assigning a totally stubby area

By default, the Layer 3 Switch sends summary LSAs (LSA type 3) into stub areas. You can further reduce the number of link state advertisements (LSAs) sent into a stub area by configuring the Layer 3 Switch to stop sending summary LSAs (type 3 LSAs) into the area. You can disable the summary LSAs when you are configuring the stub area or later after you have configured the area.

This feature disables origination of summary LSAs, but the Layer 3 Switch still accepts summary LSAs from OSPF neighbors and floods them to other neighbors. The Layer 3 Switch can form adjacencies with other routers regardless of whether summarization is enabled or disabled for areas on each router.

When you enter a command or apply a Web management option to disable the summary LSAs, the change takes effect immediately. If you apply the option to a previously configured area, the Layer 3 Switch flushes all of the summary LSAs it has generated (as an ABR) from the area.

NOTE

This feature applies only when the Layer 3 Switch is configured as an Area Border Router (ABR) for the area. To completely prevent summary LSAs from being sent to the area, disable the summary LSAs on each OSPF router that is an ABR for the area.

This feature does not apply to Not-So-Stubby Areas (NSSAs).

To disable summary LSAs for a stub area, enter commands such as the following.

```
Brocade(config-ospf-router)#area 40 stub 99 no-summary
```

Syntax: `area <num> | <ip-addr> stub <cost> [no-summary]`

The `<num> | <ip-addr>` parameter specifies the area number, which can be a number or in IP address format. If you specify a number, the number can be from 0 through 18.

The `stub <cost>` parameter specifies an additional cost for using a route to or from this area and can be from 1 through 16777215. There is no default. Normal areas do not use the cost parameter.

The `no-summary` parameter applies only to stub areas and disables summary LSAs from being sent into the area.

NOTE

You can assign one area on a router interface. For example, if the system or chassis module has 16 ports, 16 areas are supported on the chassis or module.

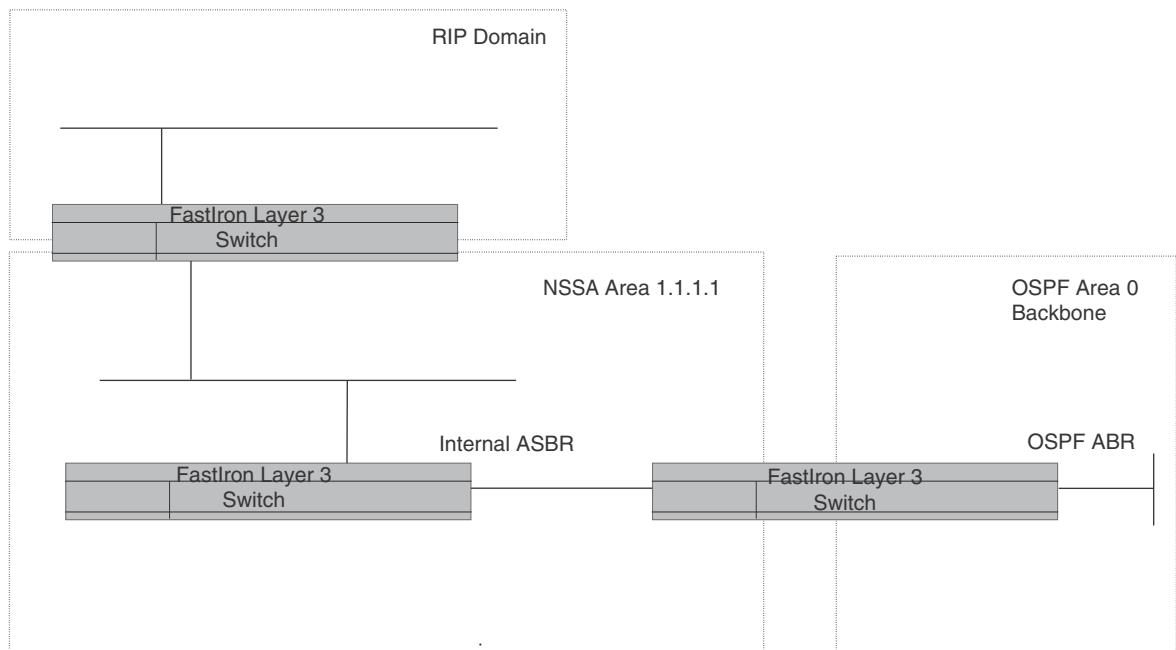

Assigning a Not-So-Stubby Area (NSSA)

The OSPF Not-So-Stubby Area (NSSA) feature enables you to configure OSPF areas that provide the benefits of stub areas, but that also are capable of importing external route information. OSPF does not flood external routes from other areas into an NSSA, but does translate and flood route information from the NSSA into other areas such as the backbone.

NSSAs are especially useful when you want to summarize Type-5 External LSAs (external routes) before forwarding them into an OSPF area. The OSPF specification (RFC 2328) prohibits summarization of Type-5 LSAs and requires OSPF to flood Type-5 LSAs throughout a routing domain. When you configure an NSSA, you can specify an address range for aggregating the external routes that the NSSA's ABR exports into other areas.

The Brocade implementation of NSSA is based on RFC 1587.

[Figure 162](#) shows an example of an OSPF network containing an NSSA.

FIGURE 162 OSPF network containing an NSSA

This example shows two routing domains, a RIP domain and an OSPF domain. The ASBR inside the NSSA imports external routes from RIP into the NSSA as Type-7 LSAs, which the ASBR floods throughout the NSSA.

The ABR translates the Type-7 LSAs into Type-5 LSAs. If an area range is configured for the NSSA, the ABR also summarizes the LSAs into an aggregate LSA before flooding the Type-5 LSAs into the backbone.

Since the NSSA is partially “stubby” the ABR does not flood external LSAs from the backbone into the NSSA. To provide access to the rest of the Autonomous System (AS), the ABR generates a default Type-7 LSA into the NSSA.

Configuring an NSSA

To configure OSPF area 1.1.1.1 as an NSSA, enter the following commands.

```
Brocade(config)#router ospf
Brocade(config-ospf-router)#area 1.1.1.1 nssa 1
Brocade(config-ospf-router)#write memory
```

Syntax: `area <num> | <ip-addr> nssa <cost> | default-information-originate`

The `<num> | <ip-addr>` parameter specifies the area number, which can be a number or in IP address format. If you specify a number, the number can be from 0 through 18.

The `nssa <cost> | default-information-originate` parameter specifies that this is a Not-So-Stubby Area (NSSA). The `<cost>` specifies an additional cost for using a route to or from this NSSA and can be from 1 through 16777215. There is no default. Normal areas do not use the cost parameter. Alternatively, the `default-information-originate` parameter causes the Layer 3 Switch to inject the default route into the NSSA.

NOTE

The Layer 3 Switch does not inject the default route into an NSSA by default.

NOTE

You can assign one area on a router interface. For example, if the system or chassis module has 16 ports, 16 areas are supported on the chassis or module.

To configure additional parameters for OSPF interfaces in the NSSA, use the **ip ospf area...** command at the interface level of the CLI.

Configuring a summary address for the NSSA

If you want the ABR that connects the NSSA to other areas to summarize the routes in the NSSA before translating them into Type-5 LSAs and flooding them into the other areas, configure a summary address. The ABR creates an aggregate value based on the summary address. The aggregate value becomes the address that the ABR advertises instead of advertising the individual addresses represented by the aggregate.

To configure a summary address in NSSA 1.1.1.1, enter the following commands. This example assumes that you have already configured NSSA 1.1.1.1.

```
Brocade(config)#router ospf
Brocade(config-ospf-router)#summary-address 209.157.22.1 255.255.0.0
Brocade(config-ospf-router)#write memory
```

Syntax: [no] **summary-address** <ip-addr> <ip-mask>

The <ip-addr> parameter specifies the IP address portion of the range. The software compares the address with the significant bits in the mask. All network addresses that match this comparison are summarized in a single route advertised by the router.

The <ip-mask> parameter specifies the portions of the IP address that a route must contain to be summarized in the summary route. In the example above, all networks that begin with 209.157 are summarized into a single route.

Assigning an area range (optional)

You can assign a range for an area, but it is not required. Ranges allow a specific IP address and mask to represent a range of IP addresses within an area, so that only that reference range address is advertised to the network, instead of all the addresses within that range. Each area can have up to 32 range addresses.

Example

To define an area range for subnets on 193.45.5.1 and 193.45.6.2, enter the following commands.

```
Brocade(config)#router ospf
Brocade(config-ospf-router)#area 192.45.5.1 range 193.45.0.0 255.255.0.0
Brocade(config-ospf-router)#area 193.45.6.2 range 193.45.0.0 255.255.0.0
```

Syntax: **area** <num> | <ip-addr> **range** <ip-addr> <ip-mask>

The <num> | <ip-addr> parameter specifies the area number, which can be in IP address format.

The **range** <ip-addr> parameter specifies the IP address portion of the range. The software compares the address with the significant bits in the mask. All network addresses that match this comparison are summarized in a single route advertised by the router.

The `<ip-mask>` parameter specifies the portions of the IP address that a route must contain to be summarized in the summary route. In the example above, all networks that begin with 193.45 are summarized into a single route.

Assigning interfaces to an area

Once you define OSPF areas, you can assign interfaces to the areas. All router ports must be assigned to one of the defined areas on an OSPF router. When a port is assigned to an area, all corresponding subnets on that port are automatically included in the assignment.

To assign interface 1/8 to area 195.5.0.0 and then save the changes, enter the following commands.

```
Brocade(config-ospf-router)#interface e 1/8
Brocade(config-if-1/8)#ip ospf area 195.5.0.0
Brocade(config-if-1/8)#write memory
```

Modifying interface defaults

OSPF has interface parameters that you can configure. For simplicity, each of these parameters has a default value. No change to these default values is required except as needed for specific network configurations.

Port default values can be modified using the following commands at the interface configuration level of the CLI:

- **ip ospf area** `<ip-addr>`
- **ip ospf auth-change-wait-time** `<secs>`
- **ip ospf authentication-key** `[0 | 1] <string>`
- **ip ospf cost** `<num>`
- **ip ospf dead-interval** `<value>`
- **ip ospf hello-interval** `<value>`
- **ip ospf md5-authentication key-activation-wait-time** `<num>` | **key-id** `<num>` `[0 | 1]` **key** `<string>`
- **ip ospf passive**
- **ip ospf priority** `<value>`
- **ip ospf retransmit-interval** `<value>`
- **ip ospf transmit-delay** `<value>`

For a complete description of these parameters, see the summary of OSPF port parameters in the next section.

OSPF interface parameters

The following parameters apply to OSPF interfaces.

Area: Assigns an interface to a specific area. You can assign either an IP address or number to represent an OSPF Area ID. If you assign a number, it can be any value from 0 through 2,147,483,647.

Auth-change-wait-time: OSPF gracefully implements authentication changes to allow all routers to implement the change and thus prevent disruption to neighbor adjacencies. During the authentication-change interval, both the old and new authentication information is supported. The default authentication-change interval is 300 seconds (5 minutes). You change the interval to a value from 0 through 14400 seconds.

Authentication-key: OSPF supports three methods of authentication for each interface—none, simple password, and MD5. Only one method of authentication can be active on an interface at a time. The default authentication value is none, meaning no authentication is performed.

The simple password method of authentication requires you to configure an alphanumeric password on an interface. The simple password setting takes effect immediately. All OSPF packets transmitted on the interface contain this password. Any OSPF packet received on the interface is checked for this password. If the password is not present, then the packet is dropped. The password can be up to eight characters long.

The MD5 method of authentication requires you to configure a key ID and an MD5 Key. The key ID is a number from 1 through 255 and identifies the MD5 key that is being used. The MD5 key can be up to sixteen alphanumeric characters long.

Cost: Indicates the overhead required to send a packet across an interface. You can modify the cost to differentiate between 100 Mbps and 1000 Mbps (1 Gbps) links. The default cost is calculated by dividing 100 million by the bandwidth. For 10 Mbps links, the cost is 10. The cost for both 100 Mbps and 1000 Mbps links is 1, because the speed of 1000 Mbps was not in use at the time the OSPF cost formula was devised.

Dead-interval: Indicates the number of seconds that a neighbor router waits for a hello packet from the current router before declaring the router down. The value can be from 1 through 65535 seconds. The default is 40 seconds.

Hello-interval: Represents the length of time between the transmission of hello packets. The value can be from 1 through 65535 seconds. The default is 10 seconds.

MD5-authentication activation wait time: The number of seconds the Layer 3 Switch waits until placing a new MD5 key into effect. The wait time provides a way to gracefully transition from one MD5 key to another without disturbing the network. The wait time can be from 0 through 14400 seconds. The default is 300 seconds (5 minutes).

MD5-authentication key ID and key: A method of authentication that requires you to configure a key ID and an MD5 key. The key ID is a number from 1 through 255 and identifies the MD5 key that is being used. The MD5 key consists of up to 16 alphanumeric characters. The MD5 is encrypted and included in each OSPF packet transmitted.

Passive: When you configure an OSPF interface to be passive, that interface does not send or receive OSPF route updates. By default, all OSPF interfaces are active and thus can send and receive OSPF route information. Since a passive interface does not send or receive route information, the interface is in effect a stub network. OSPF interfaces are active by default.

NOTE

This option affects all IP subnets configured on the interface. If you want to disable OSPF updates only on some of the IP subnets on the interface, use the **ospf-ignore** or **ospf-passive** parameter with the **ip address** command. Refer to [“Assigning an IP address to an Ethernet port”](#) on page 965.

Priority: Allows you to modify the priority of an OSPF router. The priority is used when selecting the designated router (DR) and backup designated routers (BDRs). The value can be from 0 through 255. The default is 1. If you set the priority to 0, the Layer 3 Switch does not participate in DR and BDR election.

Retransmit-interval: The time between retransmissions of link-state advertisements (LSAs) to adjacent routers for this interface. The value can be from 0 through 3600 seconds. The default is 5 seconds.

Transit-delay: The time it takes to transmit Link State Update packets on this interface. The value can be from 0 through 3600 seconds. The default is 1 second.

Encrypted display of the authentication string or MD5 authentication key

The optional **0 | 1** parameter with the **authentication-key** and **md5-authentication key-id** parameters affects encryption.

For added security, FastIron devices encrypt display of the password or authentication string. Encryption is enabled by default. The software also provides an optional parameter to disable encryption of a password or authentication string, on an individual OSPF area or OSPF interface basis.

When encryption of the passwords or authentication strings is enabled, they are encrypted in the CLI regardless of the access level you are using. In the Web Management Interface, the passwords or authentication strings are encrypted at the read-only access level but are visible at the read-write access level.

The encryption option can be omitted (the default) or can be one of the following:

- **0** – Disables encryption for the password or authentication string you specify with the command. The password or string is shown as clear text in the running-config and the startup-config file. Use this option if you do not want display of the password or string to be encrypted.
- **1** – Assumes that the password or authentication string you enter is the encrypted form, and decrypts the value before using it.

NOTE

If you want the software to assume that the value you enter is the clear-text form, and to encrypt display of that form, do not enter **0** or **1**. Instead, omit the encryption option and allow the software to use the default behavior.

If you specify encryption option **1**, the software assumes that you are entering the encrypted form of the password or authentication string. In this case, the software decrypts the password or string you enter before using the value for authentication. If you accidentally enter option **1** followed by the clear-text version of the password or string, authentication will fail because the value used by the software will not match the value you intended to use.

If you want to display the authentication string in the output of the **show ip ospf interface** command, enter the following commands.

```
Brocade(config)# enable password-display
Brocade# show ip ospf interface 1.1.1.1
```

The **enable password-display** command enables display of the authentication string, but only in the output of the **show ip ospf interface** command. Display of the string is still encrypted in the startup-config file and running-config. Enter the command at the global CONFIG level of the CLI.

Changing the timer for OSPF authentication changes

When you make an OSPF authentication change, the software uses the authentication-change timer to gracefully implement the change. The software implements the change in the following ways:

- Outgoing OSPF packets – After you make the change, the software continues to use the old authentication to send packets, during the remainder of the current authentication-change interval. After this, the software uses the new authentication for sending packets.
- Inbound OSPF packets – The software accepts packets containing the new authentication and continues to accept packets containing the older authentication for two authentication-change intervals. After the second interval ends, the software accepts packets only if they contain the new authentication key.

The default authentication-change interval is 300 seconds (5 minutes). You change the interval to a value from 0 through 14400 seconds.

OSPF provides graceful authentication change for all the following types of authentication changes in OSPF:

- Changing authentication methods from one of the following to another of the following:
 - Simple text password
 - MD5 authentication
 - No authentication
- Configuring a new simple text password or MD5 authentication key
- Changing an existing simple text password or MD5 authentication key

To change the authentication-change interval, enter a command such as the following at the interface configuration level of the CLI.

```
Brocade(config-if-2/5)#ip ospf auth-change-wait-time 400
```

Syntax: [no] ip ospf auth-change-wait-time <secs>

The <secs> parameter specifies the interval and can be from 0 through 14400 seconds. The default is 300 seconds (5 minutes).

NOTE

For backward compatibility, the **ip ospf md5-authentication key-activation-wait-time <seconds>** command is still supported.

Block flooding of outbound LSAs on specific OSPF interfaces

By default, the Layer 3 Switch floods all outbound LSAs on all the OSPF interfaces within an area. You can configure a filter to block outbound LSAs on an OSPF interface. This feature is particularly useful when you want to block LSAs from some, but not all, of the interfaces attached to the area.

After you apply filters to block the outbound LSAs, the filtering occurs during the database synchronization and flooding.

If you remove the filters, the blocked LSAs are automatically re-flooded. You do not need to reset OSPF to re-flood the LSAs.

NOTE

You cannot block LSAs on virtual links.

To apply a filter to an OSPF interface to block flooding of outbound LSAs on the interface, enter the following commands at the Interface configuration level for that interface.

```
Brocade(config-if-1/1)#ip ospf database-filter all out
Brocade(config-if-1/1)#clear ip ospf all
```

The first command in this example blocks all outbound LSAs on the OSPF interface configured on port 1/1. The second command resets OSPF and places the command into effect immediately.

Syntax: [no] ip ospf database-filter all out

To remove the filter, enter a command such as the following.

```
Brocade(config-if-1/1)#no ip ospf database-filter all out
```

Configuring an OSPF non-broadcast interface

Layer 3 switches support Non-Broadcast Multi-Access (NBMA) networks. This feature enables you to configure an interface on a Brocade device to send OSPF traffic to its neighbor as unicast packets rather than broadcast packets.

OSPF routers generally use broadcast packets to establish neighbor relationships and broadcast route updates on Ethernet and virtual interfaces (VEs). In this release, as an alternative, you can configure the Brocade device to use unicast packets for this purpose. This can be useful in situations where multicast traffic is not feasible (for example when a firewall does not allow multicast packets).

On a non-broadcast interface, the routers at the other end of this interface must also be configured as non-broadcast and neighbor routers. There is no restriction on the number of routers sharing a non-broadcast interface (for example, through a hub or switch).

NOTE

Only Ethernet interfaces or VEs can be configured as non-broadcast interfaces.

To configure an OSPF interface as a non-broadcast interface, enable the feature on a physical interface or a VE, following the **ip ospf area** statement, and then specify the IP address of the neighbor in the OSPF configuration. The non-broadcast interface configuration must be done on the OSPF routers on both ends of the link.

For example, the following commands configure VE 20 as a non-broadcast interface.

```
Brocade(config)#int ve 20
Brocade(config-vif-20)#ip ospf area 0
Brocade(config-vif-20)#ip ospf network non-broadcast
Brocade(config-vif-20)#exit
```

Syntax: [no] ip ospf network non-broadcast

The following commands specify 1.1.20.1 as an OSPF neighbor address. The address specified must be in the same subnet as a non-broadcast interface.

```
Brocade(config)#router ospf
Brocade(config-ospf-router)#neighbor 1.1.20.1
```

For example, to configure the feature in a network with three routers connected by a hub or switch, each router must have the linking interface configured as a non-broadcast interface, and both of the other routers must be specified as neighbors.

The output of the **show ip ospf interface** command has been enhanced to display information about non-broadcast interfaces and neighbors that are configured in the same subnet.

Example of specifying OSPF neighbor address

```
Brocade#show ip ospf interface
v20,OSPF enabled
    IP Address 1.1.20.4, Area 0
    OSPF state BD, Pri 1, Cost 1, Options 2, Type non-broadcast Events 6
    Timers(sec): Transit 1, Retrans 5, Hello 10, Dead 40
    DR:  Router ID 1.1.13.1      Interface Address 1.1.20.5
    BDR: Router ID 2.2.2.1      Interface Address 1.1.20.4
    Neighbor Count = 1, Adjacent Neighbor Count= 2
    Non-broadcast neighbor config: 1.1.20.1, 1.1.20.2, 1.1.20.3, 1.1.20.5,
    Neighbor:      1.1.20.5
    Authentication-Key:None
    MD5 Authentication: Key None, Key-Id None, Auth-change-wait-time 300
```

In the Type field, “non-broadcast” indicates that this is a non-broadcast interface. When the interface type is non-broadcast, the Non-broadcast neighbor config field displays the neighbors that are configured in the same subnet. If no neighbors are configured in the same subnet, a message such as the following is displayed.

```
***Warning! no non-broadcast neighbor config in 1.1.100.1 255.255.255.0
```

Assigning virtual links

All ABRs (area border routers) must have either a direct or indirect link to the OSPF backbone area (0.0.0.0 or 0). If an ABR does not have a physical link to the area backbone, the ABR can configure a **virtual link** to another router within the same area, which has a physical connection to the area backbone.

The path for a virtual link is through an area shared by the neighbor ABR (router with a physical backbone connection), and the ABR requiring a logical connection to the backbone.

Two parameters fields must be defined for all virtual links—transit area ID and neighbor router:

- The *transit area ID* represents the shared area of the two ABRs and serves as the connection point between the two routers. This number should match the area ID value.
- The *neighbor router* field is the router ID (IP address) of the router that is physically connected to the backbone, when assigned from the router interface requiring a logical connection. When assigning the parameters from the router with the physical connection, the router ID is the IP address of the router requiring a logical connection to the backbone.

NOTE

By default, the Brocade router ID is the IP address configured on the lowest numbered loopback interface. If the Layer 3 Switch does not have a loopback interface, the default router ID is the lowest numbered IP address configured on the device. For more information or to change the router ID, refer to [“Changing the router ID”](#) on page 976.

NOTE

When you establish an area virtual link, you must configure it on both of the routers (both ends of the virtual link).

FIGURE 163 Defining OSPF virtual links within a network

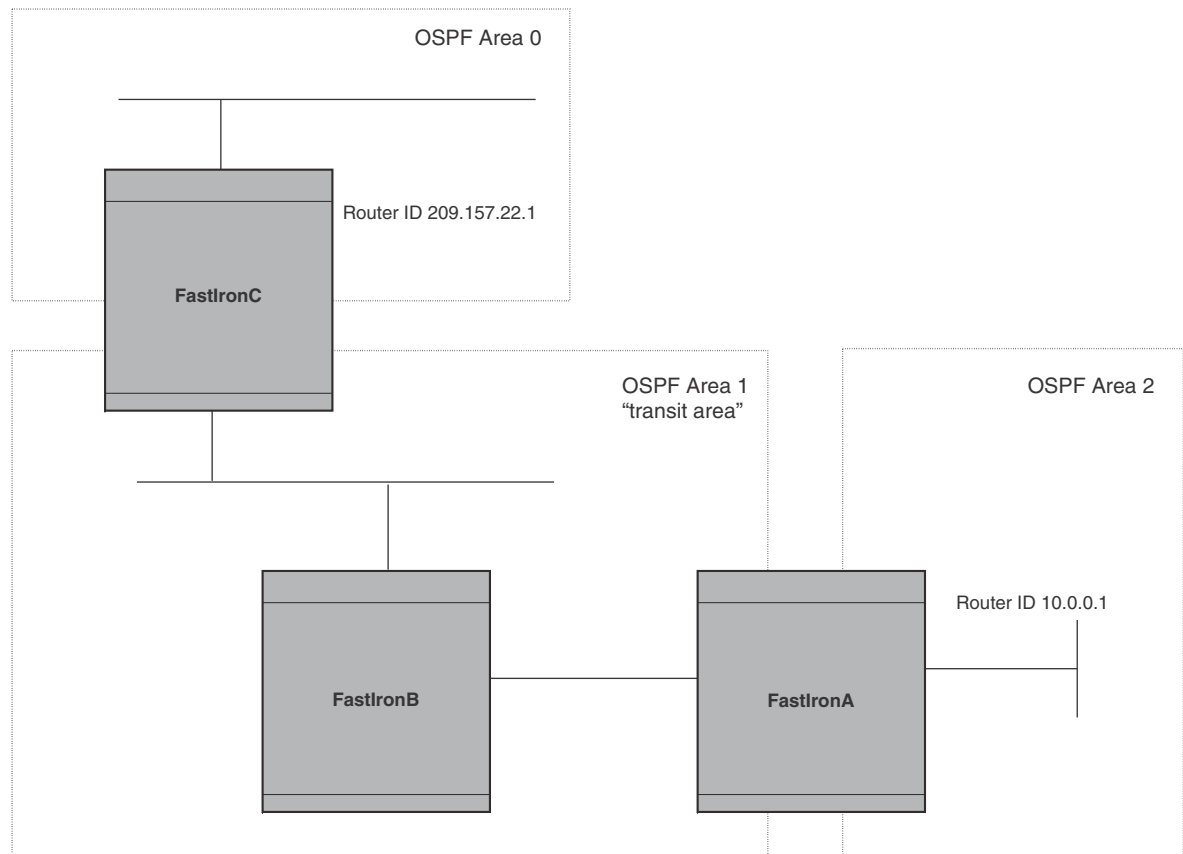

**Example**

Figure 163 shows an OSPF area border router, FastIronA, that is cut off from the backbone area (area 0). To provide backbone access to FastIronA, you can add a virtual link between FastIronA and FastIronC using area 1 as a transit area. To configure the virtual link, you define the link on the router that is at each end of the link. No configuration for the virtual link is required on the routers in the transit area.

To define the virtual link on FastIronA, enter the following commands.

```
BrocadeA(config-ospf-router)#area 1 virtual-link 209.157.22.1
BrocadeA(config-ospf-router)#write memory
```

Enter the following commands to configure the virtual link on FastIronC.

```
BrocadeC(config-ospf-router)#area 1 virtual-link 10.0.0.1
BrocadeC(config-ospf-router)#write memory
```

Syntax: `area <ip-addr> | <num> virtual-link <router-id>`

`[authentication-key | dead-interval | hello-interval | retransmit-interval | transmit-delay <value>]`

The **area** *<ip-addr> | <num>* parameter specifies the transit area.

The *<router-id>* parameter specifies the router ID of the OSPF router at the remote end of the virtual link. To display the router ID on a Brocade Layer 3 Switch, enter the **show ip** command.

Refer to [“Modifying virtual link parameters”](#) on page 1249 for descriptions of the optional parameters.

Modifying virtual link parameters

OSPF has some parameters that you can modify for virtual links. Notice that these are the same parameters as the ones you can modify for physical interfaces.

You can modify default values for virtual links using the following CLI command at the OSPF router level of the CLI, as shown in the following syntax.

Syntax: **area** *<num> | <ip-addr>* **virtual-link** *<ip-addr>* [**authentication-key** [0 | 1] *<string>*] [**dead-interval** *<num>*] [**hello-interval** *<num>*] [**md5-authentication key-activation-wait-time** *<num>* | **key-id** *<num>*] [0 | 1] **key** *<string>*] [**retransmit-interval** *<num>*] [**transmit-delay** *<num>*]

The parameters are described in the next section.

Virtual link parameter descriptions

You can modify the following virtual link interface parameters.

Authentication Key: This parameter allows you to assign different authentication methods on a port-by-port basis. OSPF supports three methods of authentication for each interface—none, simple password, and MD5. Only one method of authentication can be active on an interface at a time.

The simple password method of authentication requires you to configure an alphanumeric password on an interface. The password can be up to eight characters long. The simple password setting takes effect immediately. All OSPF packets transmitted on the interface contain this password. All OSPF packets received on the interface are checked for this password. If the password is not present, the packet is dropped.

The MD5 method of authentication encrypts the authentication key you define. The authentication is included in each OSPF packet transmitted.

MD5 Authentication Key: When simple authentication is enabled, the key is an alphanumeric password of up to eight characters. When MD5 is enabled, the key is an alphanumeric password of up to 16 characters that is later encrypted and included in each OSPF packet transmitted. You must enter a password in this field when the system is configured to operate with either simple or MD5 authentication.

MD5 Authentication Key ID: The Key ID is a number from 1 through 255 and identifies the MD5 key that is being used. This parameter is required to differentiate among multiple keys defined on a router.

MD5 Authentication Wait Time: This parameter determines when a newly configured MD5 authentication key is valid. This parameter provides a graceful transition from one MD5 key to another without disturbing the network. All new packets transmitted after the key activation wait time interval use the newly configured MD5 Key. OSPF packets that contain the old MD5 key are accepted for up to five minutes after the new MD5 key is in operation.

The range for the key activation wait time is from 0 through 14400 seconds. The default value is 300 seconds.

Hello Interval: The length of time between the transmission of hello packets. The range is 1 through 65535 seconds. The default is 10 seconds.

Retransmit Interval: The interval between the re-transmission of link state advertisements to router adjacencies for this interface. The range is 0 through 3600 seconds. The default is 5 seconds.

Transmit Delay: The period of time it takes to transmit Link State Update packets on the interface. The range is 0 through 3600 seconds. The default is 1 second.

Dead Interval: The number of seconds that a neighbor router waits for a hello packet from the current router before declaring the router down. The range is 1 through 65535 seconds. The default is 40 seconds.

Encrypted display of the authentication string or MD5 authentication key

The optional **0** | **1** parameter with the **authentication-key** and **md5-authentication key-id** parameters affects encryption.

For added security, FastIron devices encrypt display of the password or authentication string. Encryption is enabled by default. The software also provides an optional parameter to disable encryption of a password or authentication string, on an individual OSPF area or OSPF interface basis.

When encryption of the passwords or authentication strings is enabled, they are encrypted in the CLI regardless of the access level you are using. In the Web Management Interface, the passwords or authentication strings are encrypted at the read-only access level but are visible at the read-write access level.

The encryption option can be omitted (the default) or can be one of the following:

- **0** – Disables encryption for the password or authentication string you specify with the command. The password or string is shown as clear text in the running-config and the startup-config file. Use this option if you do not want display of the password or string to be encrypted.
- **1** – Assumes that the password or authentication string you enter is the encrypted form, and decrypts the value before using it.

NOTE

If you want the software to assume that the value you enter is the clear-text form, and to encrypt display of that form, do not enter **0** or **1**. Instead, omit the encryption option and allow the software to use the default behavior.

If you specify encryption option **1**, the software assumes that you are entering the encrypted form of the password or authentication string. In this case, the software decrypts the password or string you enter before using the value for authentication. If you accidentally enter option **1** followed by the clear-text version of the password or string, authentication will fail because the value used by the software will not match the value you intended to use.

Changing the reference bandwidth for the cost on OSPF interfaces

Each interface on which OSPF is enabled has a cost associated with it. The Layer 3 Switch advertises its interfaces and their costs to OSPF neighbors. For example, if an interface has an OSPF cost of ten, the Layer 3 Switch advertises the interface with a cost of ten to other OSPF routers.

By default, an interface OSPF cost is based on the port speed of the interface. The cost is calculated by dividing the reference bandwidth by the port speed. The default reference bandwidth is 100 Mbps, which results in the following default costs:

- 10 Mbps port – 10
- All other port speeds – 1

You can change the reference bandwidth, to change the costs calculated by the software.

The software uses the following formula to calculate the cost.

$$\text{Cost} = \text{reference-bandwidth} / \text{interface-speed}$$

If the resulting cost is less than 1, the software rounds the cost up to 1. The default reference bandwidth results in the following costs:

- 10 Mbps port cost = $100/10 = 10$
- 100 Mbps port cost = $100/100 = 1$
- 1000 Mbps port cost = $100/1000 = 0.10$, which is rounded up to 1
- 155 Mbps port cost = $100/155 = 0.65$, which is rounded up to 1
- 622 Mbps port cost = $100/622 = 0.16$, which is rounded up to 1
- 2488 Mbps port cost = $100/2488 = 0.04$, which is rounded up to 1

For 10 Gbps OSPF interfaces, in order to differentiate the costs between 100 Mbps, 1000 Mbps, and 10,000 Mbps interfaces, you can set the auto-cost reference bandwidth to 10000, whereby each slower link is given a higher cost, as follows:

- 10 Mbps port cost = $10000/10 = 1000$
- 100 Mbps port cost = $10000/100 = 100$
- 1000 Mbps port cost = $10000/1000 = 10$
- 10000 Mbps port cost = $10000/10000 = 1$

The bandwidth for interfaces that consist of more than one physical port is calculated as follows:

- Trunk group – The combined bandwidth of all the ports.
- Virtual interface – The combined bandwidth of all the ports in the port-based VLAN that contains the virtual interface.

The default reference bandwidth is 100 Mbps. You can change the reference bandwidth to a value from 1 through 4294967.

If a change to the reference bandwidth results in a cost change to an interface, the Layer 3 Switch sends a link-state update to update the costs of interfaces advertised by the Layer 3 Switch.

NOTE

If you specify the cost for an individual interface, the cost you specify overrides the cost calculated by the software.

Interface types to which the reference bandwidth does not apply

Some interface types are not affected by the reference bandwidth and always have the same cost regardless of the reference bandwidth in use:

- The cost of a loopback interface is always 0.
- The cost of a virtual link is calculated using the Shortest Path First (SPF) algorithm and is not affected by the auto-cost feature.
- The bandwidth for tunnel interfaces is 9 Kbps and is not affected by the auto-cost feature.

Changing the reference bandwidth

To change the reference bandwidth, enter the **auto-cost reference-bandwidth** command at the OSPF configuration level of the CLI.

```
Brocade(config-ospf-router)#auto-cost reference-bandwidth 500
```

The reference bandwidth specified in this example results in the following costs:

- 10 Mbps port cost = $500/10 = 50$
- 100 Mbps port cost = $500/100 = 5$
- 1000 Mbps port cost = $500/1000 = 0.5$, which is rounded up to 1
- 155 Mbps port cost = $500/155 = 3.23$, which is rounded up to 4
- 622 Mbps port cost = $500/622 = 0.80$, which is rounded up to 1
- 2488 Mbps port cost = $500/2488 = 0.20$, which is rounded up to 1

The costs for 10 Mbps, 100 Mbps, and 155 Mbps ports change as a result of the changed reference bandwidth. Costs for higher-speed interfaces remain the same.

Syntax: [no] **auto-cost reference-bandwidth** <num>

The <num> parameter specifies the reference bandwidth and can be a value from 1 through 4294967. The default is 100. For 10 Gbps OSPF interfaces, in order to differentiate the costs between 100 Mbps, 1000 Mbps, and 10,000 Mbps interfaces, set the auto-cost reference bandwidth to 10000, whereby each slower link is given a higher cost.

To restore the reference bandwidth to its default value and thus restore the default costs of interfaces to their default values, enter the following command.

```
Brocade(config-ospf-router)#no auto-cost reference-bandwidth
```

Defining redistribution filters

Route redistribution imports and translates different protocol routes into a specified protocol type. On Brocade routers, redistribution is supported for static routes, OSPF, RIP, and BGP4. When you configure redistribution for RIP, you can specify that static, OSPF, or BGP4 routes are imported into RIP routes. Likewise, OSPF redistribution supports the import of static, RIP, and BGP4 routes into OSPF routes. BGP4 supports redistribution of static, RIP, and OSPF routes into BGP4.

NOTE

The Layer 3 Switch advertises the default route into OSPF even if redistribution is not enabled, and even if the default route is learned through an IBGP neighbor. IBGP routes (including the default route) are not redistributed into OSPF by OSPF redistribution (for example, by the OSPF **redistribute** command).

In [Figure 164](#) on page 1253, an administrator wants to configure the FastIron Layer 3 Switch acting as the ASBR (Autonomous System Boundary Router) between the RIP domain and the OSPF domain to redistribute routes between the two domains.

NOTE

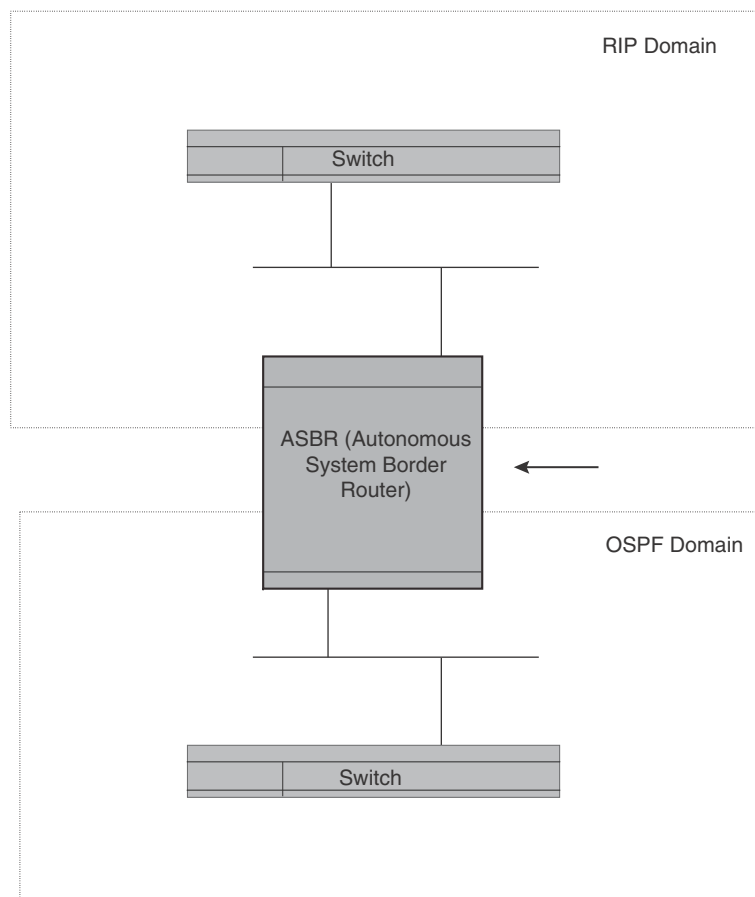

The ASBR must be running both RIP and OSPF protocols to support this activity.

To configure for redistribution, define the redistribution tables with deny and permit redistribution filters. Use the **deny redistribute** and **permit redistribute** commands for OSPF at the OSPF router level.

NOTE

Do not enable redistribution until you have configured the redistribution filters. If you enable redistribution before you configure the redistribution filters, the filters will not take affect and all routes will be distributed.

FIGURE 164 Redistributing OSPF and static routes to RIP routes

Example of redefining distribution filters

To configure the FastIron Layer 3 Switch acting as an ASBR in [Figure 164](#) to redistribute OSPF, BGP4, and static routes into RIP, enter the following commands.

```
BrocadeASBR(config)#router rip
BrocadeASBR(config-rip-router)#permit redistribute 1 all
BrocadeASBR(config-rip-router)#write memory
```

NOTE

Redistribution is permitted for all routes by default, so the **permit redistribute 1 all** command in the example above is shown for clarity but is not required.

You also have the option of specifying import of just OSPF, BGP4, or static routes, as well as specifying that only routes for a specific network or with a specific cost (metric) be imported, as shown in the following command syntax.

Syntax: **deny** | **permit redistribute** <filter-num> **all** | **bgp** | **connected** | **rip** | **static**
[**address** <ip-addr> <ip-mask> [**match-metric** <value> [**set-metric** <value>]]]

Example

To redistribute RIP, static, and BGP4 routes into OSPF, enter the following commands on the Layer 3 Switch acting as an ASBR.

```
BrocadeASBR(config)#router ospf
BrocadeASBR(config-ospf-router)#permit redistribute 1 all
BrocadeASBR(config-ospf-router)#write memory
```

Syntax: **deny** | **permit redistribute** <filter-num> **all** | **bgp** | **connected** | **rip** | **static**
address <ip-addr> <ip-mask>
[**match-metric** <value> | **set-metric** <value>]

NOTE

Redistribution is permitted for all routes by default, so the **permit redistribute 1 all** command in the example above is shown for clarity but is not required.

You also have the option of specifying import of just OSPF, BGP4, or static routes, as well as specifying that only routes for a specific network or with a specific cost (metric) be imported, as shown in the following command syntax.

For example, to enable redistribution of RIP and static IP routes into OSPF, enter the following commands.

```
Brocade(config)#router ospf
Brocade(config-ospf-router)#redistribution rip
Brocade(config-ospf-router)#redistribution static
Brocade(config-ospf-router)#write memory
```

Syntax: [**no**] **redistribution** **bgp** | **connected** | **rip** | **static** [**route-map** <map-name>]

NOTE

The **redistribution** command does not perform the same function as the **permit redistribute** and **deny redistribute** commands. The **redistribute** commands allow you to control redistribution of routes by filtering on the IP address and network mask of a route. The **redistribution** commands enable redistribution for routes of specific types (static, directly connected, and so on). Configure all your redistribution filters before enabling redistribution.

NOTE

Do not enable redistribution until you have configured the redistribution filters. If you enable redistribution before you configure the redistribution filters, the filters will not take effect and all routes will be distributed.

Preventing specific OSPF routes from being installed in the IP route table

By default, all OSPF routes in the OSPF route table are eligible for installation in the IP route table. You can configure a distribution list to explicitly deny specific routes from being eligible for installation in the IP route table.

NOTE

This feature does not block receipt of LSAs for the denied routes. The Layer 3 Switch still receives the routes and installs them in the OSPF database. The feature only prevents the software from installing the denied OSPF routes into the IP route table.

To configure an OSPF distribution list:

- Configure a standard or extended ACL that identifies the routes you want to deny. Using a standard ACL lets you deny routes based on the destination network, but does not filter based on the network mask. To also filter based on the destination network network mask, use an extended ACL.
- Configure an OSPF distribution list that uses the ACL as input.

NOTE

If you change the ACL after you configure the OSPF distribution list, you must clear the IP route table to place the changed ACL into effect. To clear the IP route table, enter the **clear ip route** command at the Privileged EXEC level of the CLI.

The following sections show how to use the CLI to configure an OSPF distribution list. Separate examples are provided for standard and extended ACLs.

NOTE

The examples show named ACLs. However, you also can use a numbered ACL as input to the OSPF distribution list.

Using a standard ACL as input to the distribution list

To use a standard ACL to configure an OSPF distribution list for denying specific routes, enter commands such as the following.

```
Brocade(config)#ip access-list standard no_ip
Brocade(config-std-nACL)#deny 4.0.0.0 0.255.255.255
Brocade(config-std-nACL)#permit any any
Brocade(config-std-nACL)#exit
Brocade(config)#router ospf
Brocade(config-ospf-router)#distribute-list no_ip in
```

The first three commands configure a standard ACL that denies routes to any 4.x.x.x destination network and allows all other routes for eligibility to be installed in the IP route table. The last three commands change the CLI to the OSPF configuration level and configure an OSPF distribution list that uses the ACL as input. The distribution list prevents routes to any 4.x.x.x destination network from entering the IP route table. The distribution list does not prevent the routes from entering the OSPF database.

Syntax: [no] **distribute-list** <ACL-name> | <ACL-id> in [<interface type>] [<interface number>]

Syntax: [no] **ip access-list standard** <ACL-name> | <ACL-id>

Syntax: **deny** | **permit** <source-ip> <wildcard>

The <ACL-name> | <ACL-id> parameter specifies the ACL name or ID.

The **in** command applies the ACL to incoming route updates.

The <interface number> parameter specifies the interface number on which to apply the ACL. Enter only one valid interface number. If necessary, use the **show interface brief** command to display a list of valid interfaces. If you do not specify an interface, the Brocade device applies the ACL to all incoming route updates.

If you do not specify an interface type and interface number, the device applies the OSPF distribution list to all incoming route updates.

The **deny** | **permit** parameter indicates whether packets that match the policy are dropped or forwarded.

The <source-ip> parameter specifies the source address for the policy. Because this ACL is input to an OSPF distribution list, the <source-ip> parameter actually is specifying the destination network of the route.

The <wildcard> parameter specifies the portion of the source address to match against. The <wildcard> is in dotted-decimal notation (IP address format). It is a four-part value, where each part is 8 bits (one byte) separated by dots, and each bit is a one or a zero. Each part is a number ranging from 0 to 255, for example 0.0.0.255. Zeros in the mask mean the packet source address must match the <source-ip>. Ones mean any value matches. For example, the <source-ip> and <wildcard> values 4.0.0.0 0.255.255.255 mean that all 4.x.x.x networks match the ACL.

If you want the policy to match on all destination networks, enter **any any**.

If you prefer to specify the wildcard (mask value) in Classless Interdomain Routing (CIDR) format, you can enter a forward slash after the IP address, then enter the number of significant bits in the mask. For example, you can enter the CIDR equivalent of “4.0.0.0 0.255.255.255” as “4.0.0.0/8”. The CLI automatically converts the CIDR number into the appropriate ACL mask (where zeros instead of ones are the significant bits) and changes the non-significant portion of the IP address into zeros.

NOTE

If you enable the software to display IP subnet masks in CIDR format, the mask is saved in the file in “/<mask-bits>” format. To enable the software to display the CIDR masks, enter the **ip show-subnet-length** command at the global CONFIG level of the CLI. You can use the CIDR format to configure the ACL entry regardless of whether the software is configured to display the masks in CIDR format.

If you use the CIDR format, the ACL entries appear in this format in the running-config and startup-config files, but are shown with subnet mask in the display produced by the **show ip access-list** command.

Using an extended ACL as input to the distribution list

You can use an extended ACL with an OSPF distribution list to filter OSPF routes based on the network mask of the destination network.

To use an extended ACL to configure an OSPF distribution list for denying specific routes, enter commands such as the following.

```
Brocade(config)#ip access-list extended no_ip
Brocade(config-ext-nACL)#deny ip 4.0.0.0 0.255.255.255 255.255.0.0 0.0.255.255
Brocade(config-ext-nACL)#permit ip any any
Brocade(config-ext-nACL)#exit
Brocade(config)#router ospf
Brocade(config-ospf-router)#distribute-list no_ip in
```

The first three commands configure an extended ACL that denies routes to any 4.x.x.x destination network with a 255.255.0.0 network mask and allows all other routes for eligibility to be installed in the IP route table. The last three commands change the CLI to the OSPF configuration level and configure an OSPF distribution list that uses the ACL as input. The distribution list prevents routes to any 4.x.x.x destination network with network mask 255.255.0.0 from entering the IP route table. The distribution list does not prevent the routes from entering the OSPF database.

Syntax: [no] ip access-list extended <ACL-name> | <ACL-id>

Syntax: deny | permit <ip-protocol> <source-ip> <wildcard> <destination-ip> <wildcard>

The <ACL-name> | <ACL-id> parameter specifies the ACL name or ID.

The **deny** | **permit** parameter indicates whether packets that match the policy are dropped or forwarded.

The <ip-protocol> parameter indicates the type of IP packet you are filtering. When using an extended ACL as input for an OSPF distribution list, specify **ip**.

Because this ACL is input to an OSPF distribution list, the <source-ip> parameter actually specifies the destination network of the route.

The <wildcard> parameter specifies the portion of the source address to match against. The <wildcard> is in dotted-decimal notation (IP address format). It is a four-part value, where each part is 8 bits (one byte) separated by dots, and each bit is a one or a zero. Each part is a number ranging from 0 to 255, for example 0.0.0.255. Zeros in the mask mean the packet source address must match the <source-ip>. Ones mean any value matches. For example, the <source-ip> and <wildcard> values 4.0.0.0 0.255.255.255 mean that all 4.x.x.x networks match the ACL.

If you want the policy to match on all network addresses, enter **any any**.

If you prefer to specify the wildcard (mask value) in Classless Interdomain Routing (CIDR) format, you can enter a forward slash after the IP address, then enter the number of significant bits in the mask. For example, you can enter the CIDR equivalent of “4.0.0.0 0.255.255.255” as “4.0.0.0/8”. The CLI automatically converts the CIDR number into the appropriate ACL mask (where zeros instead of ones are the significant bits) and changes the non-significant portion of the IP address into zeros.

NOTE

If you enable the software to display IP subnet masks in CIDR format, the mask is saved in the file in “/<mask-bits>” format. To enable the software to display the CIDR masks, enter the **ip show-subnet-length** command at the global CONFIG level of the CLI. You can use the CIDR format to configure the ACL entry regardless of whether the software is configured to display the masks in CIDR format.

If you use the CIDR format, the ACL entries appear in this format in the running-config and startup-config files, but are shown with subnet mask in the display produced by the **show ip access-list** commands.

Because this ACL is input to an OSPF distribution list, the <destination-ip> parameter actually specifies the subnet mask of the route.

The <wildcard> parameter specifies the portion of the subnet mask to match against. For example, the <destination-ip> and <wildcard> values 255.255.255.255 0.0.0.255 mean that subnet mask /24 and longer match the ACL.

If you want the policy to match on all network masks, enter **any any**.

Modifying the default metric for redistribution

The default metric is a global parameter that specifies the cost applied to all OSPF routes by default. The default value is 10. You can assign a cost from 1 through 15.

NOTE

You also can define the cost on individual interfaces. The interface cost overrides the default cost.

To assign a default metric of 4 to all routes imported into OSPF, enter the following commands.

```
Brocade(config)#router ospf
Brocade(config-ospf-router)#default-metric 4
```

Syntax: **default-metric** <value>

The <value> can be from 1 through 16,777,215. The default is 10.

Enabling route redistribution

To enable route redistribution, use one of the following methods.

NOTE

Do not enable redistribution until you have configured the redistribution filters. Otherwise, you might accidentally overload the network with routes you did not intend to redistribute.

To enable redistribution of RIP and static IP routes into OSPF, enter the following commands.

```
Brocade(config)#router ospf
Brocade(config-ospf-router)#redistribution rip
Brocade(config-ospf-router)#redistribution static
Brocade(config-ospf-router)#write memory
```

Example using a route map

To configure a route map and use it for redistribution of routes into OSPF, enter commands such as the following.

```
Brocade(config)#ip route 1.1.0.0 255.255.0.0 207.95.7.30
Brocade(config)#ip route 1.2.0.0 255.255.0.0 207.95.7.30
Brocade(config)#ip route 1.3.0.0 255.255.0.0 207.95.7.30
Brocade(config)#ip route 4.1.0.0 255.255.0.0 207.95.6.30
Brocade(config)#ip route 4.2.0.0 255.255.0.0 207.95.6.30
Brocade(config)#ip route 4.3.0.0 255.255.0.0 207.95.6.30
Brocade(config)#ip route 4.4.0.0 255.255.0.0 207.95.6.30 5
Brocade(config)#route-map abc permit 1
Brocade(config-route-map abc)#match metric 5
Brocade(config-route-map abc)#set metric 8
Brocade(config-route-map abc)#router ospf
Brocade(config-ospf-router)#redistribution static route-map abc
```

The commands in this example configure some static IP routes, then configure a route map and use the route map for redistributing static IP routes into OSPF.

The **ip route** commands configure the static IP routes. The **route-map** command begins configuration of a route map called “abc”. The number indicates the route map entry (called the “instance”) you are configuring. A route map can contain multiple entries. The software compares packets to the route map entries in ascending numerical order and stops the comparison once a match is found.

The **match** command in the route map matches on routes that have 5 for their metric value (cost). The **set** command changes the metric in routes that match the route map to 8.

The **redistribution static** command enables redistribution of static IP routes into OSPF, and uses route map “abc” to control the routes that are redistributed. In this example, the route map allows a static IP route to be redistributed into OSPF only if the route has a metric of 5, and changes the metric to 8 before placing the route into the OSPF route table.

Syntax: [no] redistribution bgp | connected | rip | static [route-map <map-name>]

The **bgp | connected | rip | static** parameter specifies the route source.

The **route-map <map-name>** parameter specifies the route map name. The following match parameters are valid for OSPF redistribution:

- **match ip address | next-hop <ACL-num>**
- **match metric <num>**
- **match tag <tag-value>**

The following set parameters are valid for OSPF redistribution:

- **set ip next hop <ip-addr>**
- **set metric [+ | -]<num> | none**
- **set metric-type type-1 | type-2**
- **set tag <tag-value>**

NOTE

You must configure the route map before you configure a redistribution filter that uses the route map.

NOTE

When you use a route map for route redistribution, the software disregards the permit or deny action of the route map.

NOTE

For an external route that is redistributed into OSPF through a route map, the metric value of the route remains the same unless the metric is set by a **set metric** command inside the route map. The **default-metric <num>** command has no effect on the route. This behavior is different from a route that is redistributed without using a route map. For a route redistributed without using a route map, the metric is set by the **default-metric <num>** command.

The following command shows the result of the redistribution filter. Because only one of the static IP routes configured above matches the route map, only one route is redistributed. Notice that the route metric is 5 before redistribution but is 8 after redistribution.

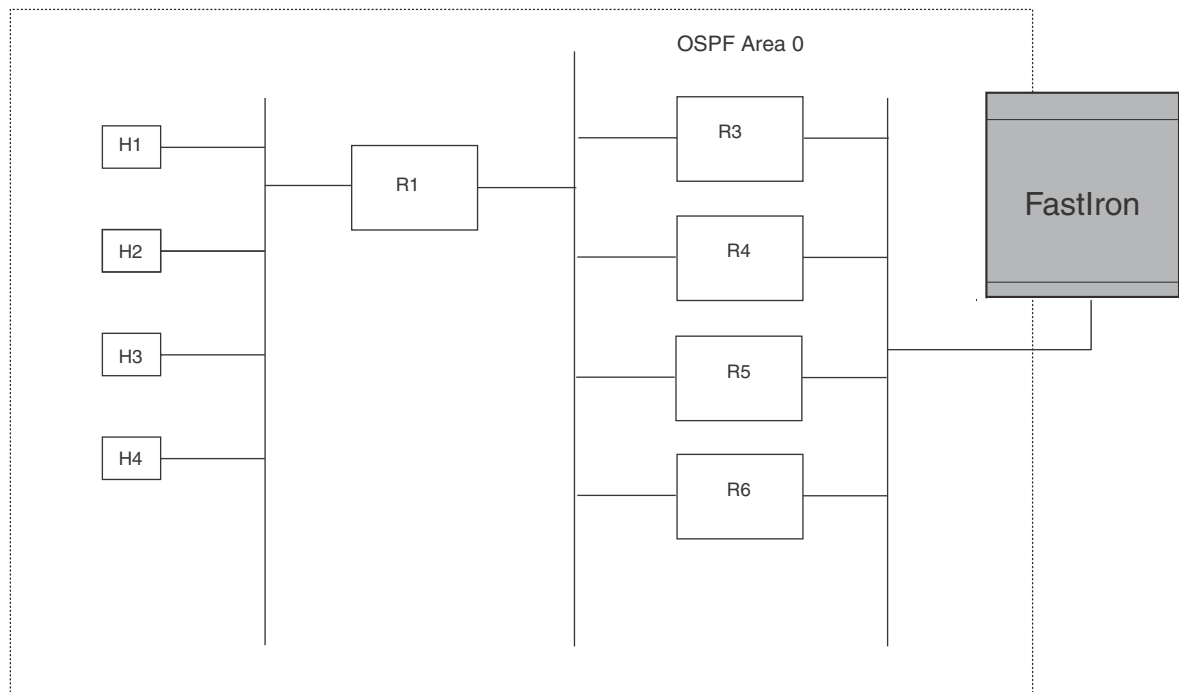

```
Brocade#show ip ospf database external extensive
```

Index	Aging	LS ID	Router	Netmask	Metric	Flag
1	2	4.4.0.0	10.10.10.60	ffff0000	80000008	0000

Disabling or re-enabling load sharing

Brocade routers can load share among up to eight equal-cost IP routes to a destination. By default, IP load sharing is enabled. The default is 4 equal-cost paths but you can specify from 2 to 6 paths.

The router software can use the route information it learns through OSPF to determine the paths and costs. [Figure 165](#) shows an example of an OSPF network containing multiple paths to a destination (in this case, R1).

FIGURE 165 Example OSPF network with four equal-cost paths

In the example in [Figure 165](#), the Brocade switch has four paths to R1:

- FI->R3
- FI->R4
- FI->R5
- FI->R6

Normally, the Brocade switch will choose the path to the R1 with the lower metric. For example, if R3 metric is 1400 and R4 metric is 600, the Brocade switch will always choose R4.

However, suppose the metric is the same for all four routers in this example. If the costs are the same, the switch now has four equal-cost paths to R1. To allow the switch to load share among the equal cost routes, enable IP load sharing. The software supports four equal-cost OSPF paths by default when you enable load sharing. You can specify from 2 to 6 paths.

NOTE

The Brocade switch is not source routing in these examples. The switch is concerned only with the paths to the next-hop routers, not the entire paths to the destination hosts.

OSPF load sharing is enabled by default when IP load sharing is enabled. To configure IP load sharing parameters, refer to [“Configuring IP load sharing”](#) on page 1001.

Configuring external route summarization

When the Layer 3 Switch is an OSPF Autonomous System Boundary Router (ASBR), you can configure it to advertise one external route as an aggregate for all redistributed routes that are covered by a specified address range.

When you configure an address range, the range takes effect immediately. All the imported routes are summarized according to the configured address range. Imported routes that have already been advertised and that fall within the range are flushed out of the AS and a single route corresponding to the range is advertised.

If a route that falls within a configured address range is imported by the Layer 3 Switch, no action is taken if the Layer 3 Switch has already advertised the aggregate route; otherwise the Layer 3 Switch advertises the aggregate route. If an imported route that falls within a configured address range is removed by the Layer 3 Switch, no action is taken if there are other imported routes that fall within the same address range; otherwise the aggregate route is flushed.

You can configure up to 32 address ranges. The Layer 3 Switch sets the forwarding address of the aggregate route to zero and sets the tag to zero.

If you delete an address range, the advertised aggregate route is flushed and all imported routes that fall within the range are advertised individually.

If an external LSDB overflow condition occurs, all aggregate routes are flushed out of the AS, along with other external routes. When the Layer 3 Switch exits the external LSDB overflow condition, all the imported routes are summarized according to the configured address ranges.

NOTE

If you use redistribution filters in addition to address ranges, the Layer 3 Switch applies the redistribution filters to routes first, then applies them to the address ranges.

NOTE

If you disable redistribution, all the aggregate routes are flushed, along with other imported routes.

To configure a summary address for OSPF routes, enter commands such as the following.

```
Brocade(config-ospf-router)#summary-address 10.1.0.0 255.255.0.0
```

The command in this example configures summary address 10.1.0.0, which includes addresses 10.1.1.0, 10.1.2.0, 10.1.3.0, and so on. For all of these networks, only the address 10.1.0.0 (the parent route) is advertised in external LSAs. However, if the parent route has not been configured with a summary address, or if the summary address for the parent route is configured after the child route, the Layer 3 switch will advertise all routes. For example:

```
router ospf
area 0
summary-address 10.1.1.0 255.255.0.0 -> Advertised
summary-address 10.1.2.0 255.255.0.0 -> Advertised
summary-address 10.0.0.0 255.0.0.0 -> Advertised
```

Syntax: `summary-address <ip-addr> <ip-mask>`

The `<ip-addr>` parameter specifies the network address.

The `<ip-mask>` parameter specifies the network mask.

To display the configured summary addresses, use the **show ip ospf config** command at any level of the CLI. The summary addresses display at the bottom of the output as shown in the following example.

```
Brocade#show ip ospf config

some lines omitted for brevity...

OSPF Redistribution Address Ranges currently defined:
Range-Address      Subnetmask
1.0.0.0            255.0.0.0
1.0.1.0            255.255.255.0
1.0.2.0            255.255.255.0
```

Syntax: **show ip ospf config**

Configuring default route origination

When the Layer 3 Switch is an OSPF Autonomous System Boundary Router (ASBR), you can configure it to automatically generate a default external route into an OSPF routing domain. This feature is called “default route origination” or “default information origination”.

By default, Brocade Layer 3 Switches do not advertise the default route into the OSPF domain. If you want the Layer 3 Switch to advertise the OSPF default route, you must explicitly enable default route origination.

When you enable OSPF default route origination, the Layer 3 Switch advertises a type 5 default route that is flooded throughout the AS (except stub areas and NSSAs). In addition, internal NSSA ASBRs advertise their default routes as translatable type 7 default routes.

The Layer 3 Switch advertises the default route into OSPF even if OSPF route redistribution is not enabled, and even if the default route is learned through an IBGP neighbor.

NOTE

Brocade Layer 3 Switches never advertise the OSPF default route, regardless of other configuration parameters, unless you explicitly enable default route origination using the following method.

If the Layer 3 Switch is an ASBR, you can use the “always” option when you enable the default route origination. The always option causes the ASBR to create and advertise a default route if it does not already have one configured.

If default route origination is enabled and you disable it, the default route originated by the Layer 3 Switch is flushed. Default routes generated by other OSPF routers are not affected. If you re-enable the feature, the feature takes effect immediately and thus does not require you to reload the software.

NOTE

The ABR (Layer 3 Switch) will not inject the default route into an NSSA by default and the command described in this section will not cause the Layer 3 Switch to inject the default route into the NSSA. To inject the default route into an NSSA, use the **area <num> | <ip-addr> nssa default-information-originate** command. Refer to [“Assigning a Not-So-Stubby Area \(NSSA\)”](#) on page 1239.

To enable default route origination, enter the **default-information-originate** command.

```
Brocade(config-ospf-router)#default-information-originate
```

To disable the feature, enter the **no default-information-originate** command.

```
Brocade(config-ospf-router)#no default-information-originate
```

Syntax: **[no] default-information-originate [always] [metric <value>] [metric-type <type>]**

The **always** parameter advertises the default route regardless of whether the router has a default route. This option is disabled by default.

The **metric <value>** parameter specifies a metric for the default route. If this option is not used, the default metric is used for the route.

The **metric-type <type>** parameter specifies the external link type associated with the default route advertised into the OSPF routing domain. The <type> can be one of the following:

- 1 – Type 1 external route
- 2 – Type 2 external route

If you do not use this option, the default redistribution metric type is used for the route type.

NOTE

If you specify a metric and metric type, the values you specify are used even if you do not use the **always** option.

Modifying SPF timers

The Layer 3 Switch uses the following timers when calculating the shortest path for OSPF routes:

- **SPF delay** – When the Layer 3 Switch receives a topology change, the software waits before it starts a Shortest Path First (SPF) calculation. By default, the software waits five seconds. You can configure the SPF delay to a value from 0 through 65535 seconds. If you set the SPF delay to 0 seconds, the software immediately begins the SPF calculation after receiving a topology change.
- **SPF hold time** – The Layer 3 Switch waits for a specific amount of time between consecutive SPF calculations. By default, the Layer 3 Switch waits ten seconds. You can configure the SPF hold time to a value from 0 through 65535 seconds. If you set the SPF hold time to 0 seconds, the software does not wait between consecutive SPF calculations.

You can set the delay and hold time to lower values to cause the Layer 3 Switch to change to alternate paths more quickly in the event of a route failure. Note that lower values require more CPU processing time.

You can change one or both of the timers. To do so, enter commands such as the following.

```
Brocade(config-ospf-router)#timers spf 10 20
```

The command in this example changes the SPF delay to 10 seconds and changes the SPF hold time to 20 seconds.

Syntax: **timers spf <delay> <hold-time>**

The <delay> parameter specifies the SPF delay.

The <hold-time> parameter specifies the SPF hold time.

To set the timers back to their default values, enter a command such as the following.

```
Brocade(config-ospf-router)#no timers spf 10 20
```

Modifying the redistribution metric type

The redistribution metric type is used by default for all routes imported into OSPF unless you specify different metrics for individual routes using redistribution filters. Type 2 specifies a big metric (three bytes). Type 1 specifies a small metric (two bytes). The default value is type 2.

To modify the default value to type 1, enter the following command.

```
Brocade(config-ospf-router)#metric-type type1
```

Syntax: `metric-type type1 | type2`

Administrative distance

Brocade Layer 3 Switches can learn about networks from various protocols, including Border Gateway Protocol version 4 (BGP4), RIP, and OSPF. Consequently, the routes to a network may differ depending on the protocol from which the routes were learned. The default administrative distance for OSPF routes is 110. Refer to [“Changing administrative distances”](#) on page 1374 for a list of the default distances for all route sources.

The router selects one route over another based on the source of the route information. To do so, the router can use the administrative distances assigned to the sources. You can bias the Layer 3 Switch decision by changing the default administrative distance for RIP routes.

Configuring administrative distance based on route type

You can configure a unique administrative distance for each type of OSPF route. For example, you can use this feature to prefer a static route over an OSPF inter-area route but you also want to prefer OSPF intra-area routes to static routes.

The distance you specify influences the choice of routes when the Layer 3 Switch has multiple routes for the same network from different protocols. The Layer 3 Switch prefers the route with the lower administrative distance.

You can specify unique default administrative distances for the following route types:

- Intra-area routes
- Inter-area routes
- External routes

The default for all these OSPF route types is 110.

NOTE

This feature does not influence the choice of routes within OSPF. For example, an OSPF intra-area route is always preferred over an OSPF inter-area route, even if the intra-area route distance is greater than the inter-area route distance.

To change the default administrative distances for inter-area routes, intra-area routes, and external routes, enter the following command.

```
Brocade(config-ospf-router)#distance external 100
Brocade(config-ospf-router)#distance inter-area 90
Brocade(config-ospf-router)#distance intra-area 80
```

Syntax: `[no] distance external | inter-area | intra-area <distance>`

The **external | inter-area | intra-area** parameter specifies the route type for which you are changing the default administrative distance.

The **<distance>** parameter specifies the new distance for the specified route type. Unless you change the distance for one of the route types using commands such as those shown above, the default is 110.

To reset the administrative distance to its system default (110), enter a command such as the following.

```
Brocade(config-ospf-router)#no distance external 100
```

Configuring OSPF group Link State Advertisement (LSA) pacing

The Layer 3 Switch paces LSA refreshes by delaying the refreshes for a specified time interval instead of performing a refresh each time an individual LSA refresh timer expires. The accumulated LSAs constitute a group, which the Layer 3 Switch refreshes and sends out together in one or more packets.

The pacing interval, which is the interval at which the Layer 3 Switch refreshes an accumulated group of LSAs, is configurable to a range from 10 through 1800 seconds (30 minutes). The default is 240 seconds (four minutes). Thus, every four minutes, the Layer 3 Switch refreshes the group of accumulated LSAs and sends the group together in the same packets.

Usage guidelines for configuring OSPF group LSA pacing

The pacing interval is inversely proportional to the number of LSAs the Layer 3 Switch is refreshing and aging. For example, if you have approximately 10,000 LSAs, decreasing the pacing interval enhances performance. If you have a very small database (40 to 100 LSAs), increasing the pacing interval to 10 to 20 minutes might enhance performance slightly.

Changing the LSA pacing interval

To change the LSA pacing interval to two minutes (120 seconds), enter the following command.

```
Brocade(config-ospf-router)#timers lsa-group-pacing 120
```

Syntax: [no] **timers lsa-group-pacing** <secs>

The **<secs>** parameter specifies the number of seconds and can be from 10 through 1800 (30 minutes). The default is 240 seconds (4 minutes).

To restore the pacing interval to its default value, enter the following command.

```
Brocade(config-ospf-router)#no timers lsa-group-pacing
```

Modifying OSPF traps generated

OSPF traps as defined by RFC 1850 are supported on Brocade routers. OSPF trap generation is enabled on the router, by default.

When using the CLI, you can disable all or specific OSPF trap generation by entering the following CLI command.

```
Brocade(config-ospf-router)#no snmp-server trap ospf
```

Syntax: `[no] snmp-server trap ospf`

To later re-enable the trap feature, enter **snmp-server trap ospf**.

To disable a specific OSPF trap, enter the command as **no snmp-server trap ospf <ospf-trap>**.

These commands are at the OSPF router level of the CLI.

Here is a summary of OSPF traps supported on Brocade routers, their corresponding CLI commands, and their associated MIB objects from RFC 1850:

- **interface-state-change-trap** – [MIB object: OspfIfStateChange]
- **virtual-interface-state-change-trap** – [MIB object: OspfVirtIfStateChange]
- **neighbor-state-change-trap** – [MIB object: ospfNbrStateChange]
- **virtual-neighbor-state-change-trap** – [MIB object: ospfVirtNbrStateChange]
- **interface-config-error-trap** – [MIB object: ospfIfConfigError]
- **virtual-interface-config-error-trap** – [MIB object: ospfVirtIfConfigError]
- **interface-authentication-failure-trap** – [MIB object: ospfIfAuthFailure]
- **virtual-interface-authentication-failure-trap** – [MIB object: ospfVirtIfAuthFailure]
- **interface-receive-bad-packet-trap** – [MIB object: ospfIfRxBadPacket]
- **virtual-interface-receive-bad-packet-trap** – [MIB object: ospfVirtIfRxBadPacket]
- **interface-retransmit-packet-trap** – [MIB object: ospfTxRetransmit]
- **virtual-interface-retransmit-packet-trap** – [MIB object: ospfVirtIfTxRetransmit]
- **originate-lsa-trap** – [MIB object: ospfOriginateLsa]
- **originate-maxage-lsa-trap** – [MIB object: ospfMaxAgeLsa]
- **link-state-database-overflow-trap** – [MIB object: ospfLsdbOverflow]
- **link-state-database-approaching-overflow-trap** – [MIB object: ospfLsdbApproachingOverflow]

Example

To stop an OSPF trap from being collected, use the CLI command: **no trap <ospf-trap>**, at the OSPF router level of the CLI. To disable reporting of the neighbor-state-change-trap, enter the following command.

```
Brocade(config-ospf-router)#no trap neighbor-state-change-trap
```

Example

To reinstate the trap, enter the following command.

```
Brocade(config-ospf-router)#trap neighbor-state-change-trap
```

Syntax: `[no] trap <ospf-trap>`

Specifying the types of OSPF Syslog messages to log

You can specify which kinds of OSPF-related Syslog messages are logged. By default, the only OSPF messages that are logged are those indicating possible system errors. If you want other kinds of OSPF messages to be logged, you can configure the Brocade device to log them.

NOTE

This feature is not supported on FWS devices.

For example, to specify that all OSPF-related Syslog messages be logged, enter the following commands.

```
Brocade(config)#router ospf
Brocade(config-ospf-router)#log all
```

Syntax: [no] **log all** | **adjacency** | **bad_packet** [checksum] | **database** | **memory** | **retransmit**

The **all** option causes all OSPF-related Syslog messages to be logged. If you later disable this option with the **no log all** command, the OSPF logging options return to their default settings.

The **adjacency** option logs essential OSPF neighbor state changes, especially on error cases. This option is disabled by default.

The **bad_packet checksum** option logs all OSPF packets that have checksum errors. This option is enabled by default.

The **bad_packet** option logs all other bad OSPF packets. This option is disabled by default.

The **database** option logs OSPF LSA-related information. This option is disabled by default.

The **memory** option logs abnormal OSPF memory usage. This option is enabled by default.

The **retransmit** option logs OSPF retransmission activities. This option is disabled by default.

Modifying the OSPF standard compliance setting

Brocade routers are configured, by default, to be compliant with the RFC 1583 OSPF V2 specification.

To configure a router to operate with the latest OSPF standard, RFC 2178, enter the following commands.

```
Brocade(config)#router ospf
Brocade(config-ospf-router)#no rfc1583-compatibility
```

Syntax: [no] **rfc1583-compatibility**

Modifying the exit overflow interval

If a database overflow condition occurs on a router, the router eliminates the condition by removing entries that originated on the router. The exit overflow interval allows you to set how often a Layer 3 Switch checks to see if the overflow condition has been eliminated. The default value is 0. The range is 0 through 86400 seconds (24 hours). If the configured value of the database overflow interval is zero, then the router never leaves the database overflow condition.

NOTE

FastIron devices dynamically allocate OSPF memory as needed. Refer to [“Dynamic OSPF memory”](#) on page 1234.

To modify the exit overflow interval to 60 seconds, enter the following command.

```
Brocade(config-ospf-router)#database-overflow-interval 60
```

Syntax: **database-overflow-interval** <value>

The <value> can be from 0 through 86400 seconds. The default is 0 seconds.

Configuring an OSPF point-to-point link

In an OSPF point-to-point link, a direct Layer 3 connection exists between a single pair of OSPF routers, without the need for Designated and Backup Designated routers. In a point-to-point link, neighboring routers become adjacent whenever they can communicate directly. In contrast, in broadcast and non-broadcast multi-access (NBMA) networks, the Designated Router and the Backup Designated Router become adjacent to all other routers attached to the network.

Configuration notes and limitations for OSPF point-to-point link

- This feature is supported on Gbps Ethernet and 10 Gbps Ethernet interfaces.
- This feature is supported on physical interfaces. It is not supported on virtual interfaces.
- Brocade supports numbered point-to-point networks, meaning the OSPF router must have an IP interface address which uniquely identifies the router over the network. Brocade does not support unnumbered point-to-point networks.

Configuration syntax for OSPF point-to-point link

To configure an OSPF point-to-point link, enter commands such as the following.

```
Brocade(config)#interface eth 1/5
Brocade(config-if-1/5)#ip ospf network point-to-point
```

This command configures an OSPF point-to-point link on Interface 5 in slot 1.

Syntax: [no] ip ospf network point-to-point

Viewing configured OSPF point-to-point links

Refer to [“Displaying OSPF neighbor information”](#) on page 1275 and [“Displaying OSPF interface information”](#) on page 1278.

Configuring OSPF graceful restart

By default, OSPF graceful restart is enabled for the global instance.

For information about how to display OSPF graceful restart information, refer to [“Displaying OSPF graceful restart information”](#) on page 1285.

Enabling and disabling OSPF graceful restart

OSPF graceful restart is enabled by default on a FastIron Layer 3 switch. To disable it, use the following commands.

```
Brocade(config)# router ospf
Brocade(config-ospf-router)# no graceful-restart
```

To re-enable OSPF graceful restart after it has been disabled, enter the following commands.

```
Brocade(config)# router ospf
Brocade(config-ospf-router)# graceful-restart
```

Syntax: [no] graceful-restart

Configuring the OSPF graceful restart time

Use the following commands to specify the maximum amount of time advertised to a neighbor router to maintain routes from and forward traffic to a restarting router.

```
Brocade(config) router ospf
Brocade(config-ospf-router)# graceful-restart restart-time 120
```

Syntax: [no] graceful-restart restart-time <seconds>

The <seconds> variable sets the maximum restart wait time advertised to neighbors.

Possible values are from 10 through 1800 seconds.

The default value is 120 seconds.

Disabling OSPF graceful restart helper mode

By default, a FastIron Layer 3 switch supports other restarting routers as a helper. You can prevent your FastIron router from participating in OSPF graceful restart by using the following commands.

```
Brocade(config) router ospf
Brocade(config-ospf-router)# graceful-restart helper-disable
```

Syntax: [no] graceful-restart helper-disable

This command disables OSPF graceful restart helper mode.

The default behavior is to help the restarting neighbors.

Clearing OSPF information

The following kinds of OSPF information can be cleared from a Brocade OSPF link state database and OSPF routing table:

- Routes received from OSPF neighbors. You can clear routes from all OSPF neighbors, or an individual OSPF neighbor, specified either by the neighbor IP address or its router ID
- OSPF topology information, including all routes in the OSPF routing table
- All routes in the OSPF routing table that were redistributed from other protocols
- OSPF area information, including routes received from OSPF neighbors within an area, as well as routes imported into the area. You can clear area information for all OSPF areas, or for a specified OSPF area

The OSPF information is cleared dynamically when you enter the command; you do not need to remove statements from the Brocade configuration or reload the software for the change to take effect.

Clearing OSPF neighbor information

To clear information on the Brocade device about all OSPF neighbors, enter the following command.

```
Brocade#clear ip ospf neighbor
```

Syntax: clear ip ospf neighbor [ip <ip-addr> | id <ip-addr>]

This command clears all OSPF neighbors and the OSPF routes exchanged with the neighbors in the Brocade OSPF link state database. After this information is cleared, adjacencies with all neighbors are re-established, and routes with these neighbors exchanged again.

To clear information on the Brocade device about OSPF neighbor 10.10.10.1, enter the following command.

```
Brocade#clear ip ospf neighbor ip 10.10.10.1
```

This command clears the OSPF neighbor and the OSPF routes exchanged with neighbor 10.10.10.1 in the OSPF link state database in the Brocade device. After this information is cleared, the adjacency with the neighbor is re-established, and routes are exchanged again.

The neighbor router can be specified either by its IP address or its router ID. To specify the neighbor router using its IP address, use the **ip** *<ip-addr>* parameter. To specify the neighbor router using its router ID, use the **id** *<ip-addr>* parameter.

Clearing OSPF topology information

To clear OSPF topology information on the Brocade device, enter the following command.

```
Brocade#clear ip ospf topology
```

Syntax: clear ip ospf topology

This command clears all OSPF routes from the OSPF routing table, including intra-area, (which includes ABR and ASBR intra-area routes), inter-area, external type 1, external type 2, OSPF default, and OSPF summary routes.

After you enter this command, the OSPF routing table is rebuilt, and valid routes are recomputed from the OSPF link state database. When the OSPF routing table is cleared, OSPF routes in the global routing table are also recalculated. If redistribution is enabled, the routes are imported again.

Clearing redistributed routes from the OSPF routing table

To clear all routes in the OSPF routing table that were redistributed from other protocols, enter the following command.

```
Brocade#clear ip ospf redistribution
```

Syntax: clear ip ospf redistribution

This command clears all routes in the OSPF routing table that are redistributed from other protocols, including direct connected, static, RIP, and BGP. To import redistributed routes from other protocols, use the **redistribution** command at the OSPF configuration level.

Clearing information for OSPF areas

To clear information on the Brocade device about all OSPF areas, enter the following command.

```
Brocade#clear ip ospf
```

This command clears all OSPF areas, all OSPF neighbors, and the entire OSPF routing table. After this information has been cleared, adjacencies with all neighbors are re-established, and all OSPF routes are re-learned.

To clear information on the Brocade device about OSPF area 1, enter the following command.

```
Brocade#clear ip ospf area 1
```

This command clears information about the specified area ID. Information about other OSPF areas is not affected. The command clears information about all OSPF neighbors belonging to the specified area, as well as all routes imported into the specified area. Adjacencies with neighbors belonging to the area are re-established, and routes imported into the area are re-learned.

Syntax: `clear ip ospf [area <area-id>]`

The <area-id> can be specified in decimal format or in IP address format.

Displaying OSPF information

You can use CLI commands and Web management options to display the following OSPF information:

- Trap, area, and interface information – refer to [“Displaying general OSPF configuration information”](#) on page 1272.
- CPU utilization statistics – refer to [“Displaying CPU utilization statistics”](#) on page 1273.
- Area information – refer to [“Displaying OSPF area information”](#) on page 1275.
- Neighbor information – refer to [“Displaying OSPF neighbor information”](#) on page 1275.
- Interface information – refer to [“Displaying OSPF interface information”](#) on page 1278.
- Route information – refer to [“Displaying OSPF route information”](#) on page 1279.
- External link state information – refer to [“Displaying OSPF external link state information”](#) on page 1281.
- Link state information – refer to [“Displaying OSPF link state information”](#) on page 1282.
- Virtual Neighbor information – refer to [“Displaying OSPF virtual neighbor information”](#) on page 1283.
- Virtual Link information – refer to [“Displaying OSPF virtual link information”](#) on page 1284.
- ABR and ASBR information – refer to [“Displaying OSPF ABR and ASBR information”](#) on page 1284.
- Trap state information – refer to [“Displaying OSPF trap status”](#) on page 1284.
- OSPF graceful restart - refer to [“Displaying OSPF graceful restart information”](#) on page 1285.

Displaying general OSPF configuration information

To display general OSPF configuration information, enter the following command at any CLI level.

```
Brocade#show ip ospf config
Router OSPF: Enabled
Redistribution: Disabled
Default OSPF Metric: 10
OSPF Redistribution Metric: Type2

OSPF External LSA Limit: 25000

OSPF Database Overflow Interval: 0
```

RFC 1583 Compatibility: Enabled

Router id: 192.85.2.1

Interface State Change Trap:	Enabled
Virtual Interface State Change Trap:	Enabled
Neighbor State Change Trap:	Enabled
Virtual Neighbor State Change Trap:	Enabled
Interface Configuration Error Trap:	Enabled
Virtual Interface Configuration Error Trap:	Enabled
Interface Authentication Failure Trap:	Enabled
Virtual Interface Authentication Failure Trap:	Enabled
Interface Receive Bad Packet Trap:	Enabled
Virtual Interface Receive Bad Packet Trap:	Enabled
Interface Retransmit Packet Trap:	Enabled
Virtual Interface Retransmit Packet Trap:	Enabled
Originate LSA Trap:	Enabled
Originate MaxAge LSA Trap:	Enabled
Link State Database Overflow Trap:	Enabled
Link State Database Approaching Overflow Trap:	Enabled

OSPF Area currently defined:

Area-ID	Area-Type	Cost
0	normal	0

OSPF Interfaces currently defined:

Ethernet Interface: 3/1-3/2

ip ospf md5-authentication-key-activation-wait-time 300

ip ospf area 0

Ethernet Interface: v1

ip ospf md5-authentication-key-activation-wait-time 300

ip ospf area 0

Ethernet Interface: 2/1

ip ospf auth-change-wait-time 300

ip ospf cost 40

ip ospf area 0

Syntax: show ip ospf config

Displaying CPU utilization statistics

You can display CPU utilization statistics for OSPF and other IP protocols.

To display CPU utilization statistics for OSPF for the previous one-second, one-minute, five-minute, and fifteen-minute intervals, enter the following command at any level of the CLI.

Displaying OSPF information

```
Brocade#show process cpu
Process Name    5Sec(%)    1Min(%)    5Min(%)    15Min(%)    Runtime(ms)
ARP              0.01        0.03        0.09        0.22          9
BGP              0.04        0.06        0.08        0.14         13
GVRP             0.00        0.00        0.00        0.00          0
ICMP             0.00        0.00        0.00        0.00          0
IP               0.00        0.00        0.00        0.00          0
OSPF           0.03       0.06       0.09       0.12        11
RIP              0.00        0.00        0.00        0.00          0
STP              0.00        0.00        0.00        0.00          0
VRRP             0.00        0.00        0.00        0.00          0
```

If the software has been running less than 15 minutes (the maximum interval for utilization statistics), the command indicates how long the software has been running. Here is an example.

```
Brocade#show process cpu
The system has only been up for 6 seconds.
Process Name    5Sec(%)    1Min(%)    5Min(%)    15Min(%)    Runtime(ms)
ARP              0.01        0.00        0.00        0.00          0
BGP              0.00        0.00        0.00        0.00          0
GVRP             0.00        0.00        0.00        0.00          0
ICMP             0.01        0.00        0.00        0.00          1
IP               0.00        0.00        0.00        0.00          0
OSPF             0.00        0.00        0.00        0.00          0
RIP              0.00        0.00        0.00        0.00          0
STP              0.00        0.00        0.00        0.00          0
VRRP             0.00        0.00        0.00        0.00          0
```

To display utilization statistics for a specific number of seconds, enter the **show process cpu** command.

```
Brocade#show process cpu 2
Statistics for last 1 sec and 80 ms
Process Name    Sec(%)    Time(ms)
ARP              0.00        0
BGP              0.00        0
GVRP             0.00        0
ICMP             0.01        1
IP               0.00        0
OSPF             0.00        0
RIP              0.00        0
STP              0.01        0
VRRP             0.00        0
```

When you specify how many seconds' worth of statistics you want to display, the software selects the sample that most closely matches the number of seconds you specified. In this example, statistics are requested for the previous two seconds. The closest sample available is actually for the previous 1 second plus 80 milliseconds.

Syntax: **show process cpu** [*<num>*]

The *<num>* parameter specifies the number of seconds and can be from 1 through 900. If you use this parameter, the command lists the usage statistics only for the specified number of seconds. If you do not use this parameter, the command lists the usage statistics for the previous one-second, one-minute, five-minute, and fifteen-minute intervals.

Displaying OSPF area information

To display OSPF area information, enter the **show ip ospf area** command at any CLI level.

```
Brocade#show ip ospf area
Indx Area      Type Cost  SPFR ABR ASBR LSA Chksum(Hex)
1   0.0.0.0    normal 0     1    0   0   1   0000781f
2  192.147.60.0 normal 0     1    0   0   1   0000fee6
3  192.147.80.0 stub   1     1    0   0   2   000181cd
```

Syntax: **show ip ospf area** [*<area-id>*] | [*<num>*]

The *<area-id>* parameter shows information for the specified area.

The *<num>* parameter displays the entry that corresponds to the entry number you enter. The entry number identifies the entry position in the area table.

This display shows the following information.

TABLE 213 CLI display of OSPF area information

Field	Definition
Indx	The row number of the entry in the router OSPF area table.
Area	The area number.
Type	The area type, which can be one of the following: <ul style="list-style-type: none"> nssa normal stub
Cost	The area cost.
SPFR	The SPFR value.
ABR	The ABR number.
ASBR	The ABSR number.
LSA	The LSA number.
Chksum(Hex)	The checksum for the LSA packet. The checksum is based on all the fields in the packet except the age field. The Layer 3 Switch uses the checksum to verify that the packet is not corrupted.

Displaying OSPF neighbor information

To display OSPF neighbor information, enter the following command at any CLI level.

```
Brocade#show ip ospf neighbor
Port Address      Pri State      Neigh Address  Neigh ID
8   212.76.7.251    1   full        212.76.7.200   173.35.1.220
```

To display detailed OSPF neighbor information, enter the following command at any CLI level.

Displaying OSPF information

```
Brocade#show ip ospf neighbor detail
```

Port	Address	Pri	State	Neigh Address	Neigh ID	Ev	Op	Cnt
9/1	20.2.0.2	1	FULL/DR	20.2.0.1	2.2.2.2	6	2	0
Second-to-dead:39								
10/1	20.3.0.2	1	FULL/BDR	20.3.0.1	3.3.3.3	5	2	0
Second-to-dead:36								
1/1-1/8	23.5.0.1	1	FULL/DR	23.5.0.2	16.16.16.16	6	2	0
Second-to-dead:33								
2/1-2/2	23.2.0.1	1	FULL/DR	23.2.0.2	15.15.15.15	6	2	0
Second-to-dead:33								

Syntax: `show ip ospf neighbor [router-id <ip-addr>] | [<num>] | [detail]`

The **router-id** <ip-addr> parameter displays only the neighbor entries for the specified router.

The <num> parameter displays only the entry in the specified index position in the neighbor table. For example, if you enter “1”, only the first entry in the table is displayed.

The **detail** parameter displays detailed information about the neighbor routers.

These displays show the following information.

TABLE 214 CLI display of OSPF neighbor information

Field	Description
Port	The port through which the Layer 3 Switch is connected to the neighbor. The port on which an OSPF point-to-point link is configured.
Address	The IP address of this Layer 3 Switch interface with the neighbor.
Pri	The OSPF priority of the neighbor: <ul style="list-style-type: none">• For multi-access networks, the priority is used during election of the Designated Router (DR) and Backup designated Router (BDR).• For point-to-point links, this field shows one of the following values:• 1 = point-to-point link• 3 = point-to-point link with assigned subnet

TABLE 214 CLI display of OSPF neighbor information (Continued)

Field	Description
State	<p>The state of the conversation between the Layer 3 Switch and the neighbor. This field can have one of the following values:</p> <ul style="list-style-type: none"> • Down – The initial state of a neighbor conversation. This value indicates that there has been no recent information received from the neighbor. • Attempt – This state is only valid for neighbors attached to non-broadcast networks. It indicates that no recent information has been received from the neighbor. • Init – A Hello packet has recently been seen from the neighbor. However, bidirectional communication has not yet been established with the neighbor. (The router itself did not appear in the neighbor's Hello packet.) All neighbors in this state (or higher) are listed in the Hello packets sent from the associated interface. • 2-Way – Communication between the two routers is bidirectional. This is the most advanced state before beginning adjacency establishment. The Designated Router and Backup Designated Router are selected from the set of neighbors in the 2-Way state or greater. • ExStart – The first step in creating an adjacency between the two neighboring routers. The goal of this step is to decide which router is the master, and to decide upon the initial Database Description (DD) sequence number. Neighbor conversations in this state or greater are called adjacencies. • Exchange – The router is describing its entire link state database by sending Database Description packets to the neighbor. Each Database Description packet has a DD sequence number, and is explicitly acknowledged. Only one Database Description packet can be outstanding at any time. In this state, Link State Request packets can also be sent asking for the neighbor's more recent advertisements. All adjacencies in Exchange state or greater are used by the flooding procedure. In fact, these adjacencies are fully capable of transmitting and receiving all types of OSPF routing protocol packets. • Loading – Link State Request packets are sent to the neighbor asking for the more recent advertisements that have been discovered (but not yet received) in the Exchange state. • Full – The neighboring routers are fully adjacent. These adjacencies will now appear in router links and network link advertisements.
Neigh Address	<p>The IP address of the neighbor:</p> <p>For point-to-point links, the value is as follows:</p> <ul style="list-style-type: none"> • If the Pri field is "1", this value is the IP address of the neighbor router interface. • If the Pri field is "3", this is the subnet IP address of the neighbor router interface.
Neigh ID	The neighbor router ID.
Ev	The number of times the neighbor state changed.
Opt	The sum of the option bits in the Options field of the Hello packet. This information is used by Brocade technical support. Refer to Section A.2 in RFC 2178 for information about the Options field in Hello packets.
Cnt	The number of LSAs that were retransmitted.
Second-to-dead	The amount of time the Brocade device will wait for a HELLO message from each OSPF neighbor before assuming the neighbor is dead.

Displaying OSPF interface information

To display OSPF interface information, enter the **show ip ospf interface** command at any CLI level.

```
Brocade#show ip ospf interface 192.168.1.1
```

```
Ethernet 2/1,OSPF enabled
  IP Address 192.168.1.1, Area 0
  OSPF state ptr2ptr, Pri 1, Cost 1, Options 2, Type pt-2-pt Events 1
  Timers(sec): Transit 1, Retrans 5, Hello 10, Dead 40
  DR:  Router ID 0.0.0.0          Interface Address 0.0.0.0
  BDR: Router ID 0.0.0.0          Interface Address 0.0.0.0
  Neighbor Count = 0, Adjacent Neighbor Count= 1
  Neighbor: 2.2.2.2
  Authentication-Key:None
  MD5 Authentication: Key None, Key-Id None, Auth-change-wait-time 300
```

Syntax: **show ip ospf interface** [*<ip-addr>*]

The *<ip-addr>* parameter displays the OSPF interface information for the specified IP address.

The following table defines the highlighted fields shown in the above example output of the **show ip ospf interface** command.

TABLE 215 Output of the **show ip ospf interface** command

Field	Definition
IP Address	The IP address of the interface.
OSPF state	ptr2ptr (point to point)
Pri	The link ID as defined in the router-LSA. This value can be one of the following: <ul style="list-style-type: none"> 1 = point-to-point link 3 = point-to-point link with an assigned subnet
Cost	The configured output cost for the interface.
Options	OSPF Options (Bit7 - Bit0): <ul style="list-style-type: none"> unused:1 opaque:1 summary:1 dont_propagate:1 nssa:1 multicast:1 externals:1 tos:1
Type	The area type, which can be one of the following: <ul style="list-style-type: none"> Broadcast = 0x01 NBMA = 0x02 Point to Point = 0x03 Virtual Link = 0x04 Point to Multipoint = 0x05

TABLE 215 Output of the **show ip ospf interface** command (Continued)

Field	Definition
Events	OSPF Interface Event: <ul style="list-style-type: none"> • Interface_Up = 0x00 • Wait_Timer = 0x01 • Backup_Seen = 0x02 • Neighbor_Change = 0x03 • Loop_Indication = 0x04 • Unloop_Indication = 0x05 • Interface_Down = 0x06 • Interface_Passive = 0x07
Adjacent Neighbor Count	The number of adjacent neighbor routers.
Neighbor:	The neighbor router ID.

Displaying OSPF route information

To display OSPF route information for the router, enter the **show ip ospf routes** command at any CLI level.

```
Brocade#show ip ospf routes
Index Destination      Mask                Path_Cost Type2_Cost Path_Type
1      212.95.7.0           255.255.255.0      1          0          Intra
      Adv_Router      Link_State          Dest_Type State      Tag      Flags
      173.35.1.220      212.95.7.251      Network Valid      00000000 7000
      Paths Out_Port Next_Hop            Type      Arp_Index State
      1      5/6      209.95.7.250      OSPF      8          84 00

Index Destination      Mask                Path_Cost Type2_Cost Path_Type
2      11.3.63.0           255.255.255.0      11         0          Inter
      Adv_Router      Link_State          Dest_Type State      Tag      Flags
      209.95.7.250      11.3.63.0          Network Valid      00000000 0000
      Paths Out_Port Next_Hop            Type      Arp_Index State
      1      5/6      209.95.7.250      OSPF      8          84 00
```

Syntax: **show ip ospf routes** [*<ip-addr>*]

The *<ip-addr>* parameter specifies a destination IP address. If you use this parameter, only the route entries for that destination are shown.

This display shows the following information.

TABLE 216 CLI Display of OSPF route information

Field	Definition
Index	The row number of the entry in the router OSPF route table.
Destination	The IP address of the route's destination.
Mask	The network mask for the route.
Path_Cost	The cost of this route path. (A route can have multiple paths. Each path represents a different exit port for the Layer 3 Switch.)
Type2_Cost	The type 2 cost of this path.

TABLE 216 CLI Display of OSPF route information (Continued)

Field	Definition
Path_Type	The type of path, which can be one of the following: <ul style="list-style-type: none"> • Inter – The path to the destination passes into another area. • Intra – The path to the destination is entirely within the local area. • External1 – The path to the destination is a type 1 external route. • External2 – The path to the destination is a type 2 external route.
Adv_Router	The OSPF router that advertised the route to this Brocade Layer 3 Switch.
Link-State	The link state from which the route was calculated.
Dest_Type	The destination type, which can be one of the following: <ul style="list-style-type: none"> • ABR – Area Border Router • ASBR – Autonomous System Boundary Router • Network – the network
State	The route state, which can be one of the following: <ul style="list-style-type: none"> • Changed • Invalid • Valid This information is used by Brocade technical support.
Tag	The external route tag.
Flags	State information for the route entry. This information is used by Brocade technical support.
Paths	The number of paths to the destination.
Out_Port	The router port through which the Layer 3 Switch reaches the next hop for this route path.
Next_Hop	The IP address of the next-hop router for this path.
Type	The route type, which can be one of the following: <ul style="list-style-type: none"> • OSPF • Static Replaced by OSPF
Arp_Index	The index position in the ARP table of the ARP entry for this path's IP address.
State	State information for the path. This information is used by Brocade technical support.

Displaying the routes that have been redistributed into OSPF

You can display the routes that have been redistributed into OSPF. To display the redistributed routes, enter the **show ip ospf redistribute route** command at any level of the CLI.

```
Brocade#show ip ospf redistribute route
 4.3.0.0 255.255.0.0 static
 3.1.0.0 255.255.0.0 static
10.11.61.0 255.255.255.0 connected
 4.1.0.0 255.255.0.0 static
```

In this example, four routes have been redistributed. Three of the routes were redistributed from static IP routes and one route was redistributed from a directly connected IP route.

Syntax: **show ip ospf redistribute route** [*<ip-addr>* *<ip-mask>*]

The `<ip-addr> <ip-mask>` parameter specifies a network prefix and network mask. Here is an example.

```
Brocade#show ip ospf redistribute route 3.1.0.0 255.255.0.0
3.1.0.0 255.255.0.0 static
```

Displaying OSPF external link state information

To display external link state information, enter the **show ip ospf database external-link-state** command at any CLI level.

```
Brocade#show ip ospf database external-link-state
```

Index	Aging	LS ID	Router	Netmask	Metric	Flag
1	1794	1.168.64.0	192.85.0.3	fffffe000	000003e8	b500 0.0.0.0
2	1794	3.215.0.0	192.85.0.3	fffff0000	000003e8	b500 0.0.0.0
3	1794	1.27.250.0	192.85.0.3	ffffffe00	000003e8	b500 0.0.0.0
4	1794	1.24.23.0	192.85.0.3	ffffff000	000003e8	b500 0.0.0.0
5	1794	1.21.52.0	192.85.0.3	ffffff000	000003e8	b500 0.0.0.0
6	1794	1.18.81.0	192.85.0.3	ffffff000	000003e8	b500 0.0.0.0
7	1794	1.15.110.0	192.85.0.3	ffffff000	000003e8	b500 0.0.0.0
8	1794	1.12.139.0	192.85.0.3	ffffff000	000003e8	b500 0.0.0.0
9	1794	1.9.168.0	192.85.0.3	ffffff000	000003e8	b500 0.0.0.0

Syntax: **show ip ospf database external-link-state** [**advertise** *<num>*] | [**extensive**] | [**link-state-id** *<ip-addr>*] | [**router-id** *<ip-addr>*] | [**sequence-number** *<num(Hex)>*] | [**status** *<num>*]

The **advertise** *<num>* parameter displays the hexadecimal data in the specified LSA packet. The *<num>* parameter identifies the LSA packet by its position in the router External LSA table. To determine an LSA packet position in the table, enter the **show ip ospf external-link-state** command to display the table. Refer to [“Displaying the data in an LSA”](#) on page 1283 for an example.

The **extensive** option displays the LSAs in decrypted format.

NOTE

You cannot use the **extensive** option in combination with other display options. The entire database is displayed.

The **link-state-id** *<ip-addr>* parameter displays the External LSAs for the LSA source specified by *<IP-addr>*.

The **router-id** *<ip-addr>* parameter shows the External LSAs for the specified OSPF router.

The **sequence-number** *<num(Hex)>* parameter displays the External LSA entries for the specified hexadecimal LSA sequence number.

The **status** *<num>* option shows status information.

This OSPF external link state display shows the following information.

TABLE 217 CLI display of OSPF external link state information

Field	Definition
Area ID	The OSPF area the router is in.
Aging	The age of the LSA, in seconds.
LS ID	The ID of the link-state advertisement from which the Layer 3 Switch learned this route.
Router	The router IP address.
Seq(hex)	The sequence number of the LSA. The OSPF neighbor that sent the LSA stamps it with a sequence number to enable the Layer 3 Switch and other OSPF routers to determine which LSA for a given route is the most recent.
Chksum	A checksum for the LSA packet, which is based on all the fields in the packet except the age field. The Layer 3 Switch uses the checksum to verify that the packet is not corrupted.
Type	The route type, which is always EXTR (external).

Displaying OSPF link state information

To display link state information, enter the **show ip ospf database link-state** command at any CLI level.

```
Brocade#show ip ospf database link-state
```

Syntax: **show ip ospf database link-state** [**advertise** <num>] | [**asbr**] | [**extensive**] | [**link-state-id** <ip-addr>] | [**network**] | [**nssa**] | [**opaque-area**] | [**router**] | [**router-id** <ip-addr>] | [**sequence-number** <num(Hex)>] | [**status** <num>] | [**summary**]

The **advertise** <num> parameter displays the hexadecimal data in the specified LSA packet. The <num> parameter identifies the LSA packet by its position in the router External LSA table. To determine an LSA packet position in the table, enter the **show ip ospf external-link-state** command to display the table. Refer to “[Displaying the data in an LSA](#)” on page 1283 for an example.

The **asbr** option shows ASBR information.

The **extensive** option displays the LSAs in decrypted format.

NOTE

You cannot use the **extensive** option in combination with other display options. The entire database is displayed.

The **link-state-id** <ip-addr> parameter displays the External LSAs for the LSA source specified by <IP-addr>.

The **network** option shows network information.

The **nssa** option shows network information.

The **opaque-area** option shows information for opaque areas.

The **router-id** <ip-addr> parameter shows the External LSAs for the specified OSPF router.

The **sequence-number** <num(Hex)> parameter displays the External LSA entries for the specified hexadecimal LSA sequence number.

The **status** *<num>* option shows status information.

The **summary** option shows summary information.

Displaying the data in an LSA

You can use the CLI to display the data the Layer 3 Switch received in a specific External LSA packet or other type of LSA packet. For example, to display the LSA data in entry 3 in the External LSA table, enter the following command.

```
Brocade#show ip ospf database external-link-state advertise 3
Index Aging  LS ID          Router          Netmask  Metric   Flag
3      619    1.27.250.0      192.85.0.3     fffffff0 000003e8 b500 0.0.0.0
LSA Header:  age: 619, options: 0x02, seq-nbr: 0x80000003, length: 36
NetworkMask: 255.255.254.0
TOS 0:  metric_type: 1, metric: 1000
        forwarding_address: 0.0.0.0
        external_route_tag: 0
```

Syntax: `show ip ospf database external-link-state [advertise <num>] | [link-state-id <ip-addr>] | [router-id <ip-addr>] | [sequence-number <num(Hex)>] | [status <num>]`

To determine an external LSA or other type of LSA index number, enter one of the following commands to display the appropriate LSA table:

- **show ip ospf database link-state advertise *<num>*** – This command displays the data in the packet for the specified LSA.
- **show ip ospf database external-link-state advertise *<num>*** – This command displays the data in the packet for the specified external LSA.

For example, to determine an external LSA index number, enter the **show ip ospf external-link-state** command.

```
Brocade#show ip ospf external-link-state

Index Aging  LS ID          Router          Netmask  Metric   Flag
1      1809    1.18.81.0      103.103.103.6   fffffff0 000003e8 b500 0.0.0.0
2       8     1.27.250.0     103.103.103.6   fffffff0 000003e8 b500 0.0.0.0
3       8     3.215.0.0      103.103.103.6   ffff0000 000003e8 b500 0.0.0.0
4       18     1.33.192.0     102.102.102.6   fffffc00 000003e8 b500 0.0.0.0
5      959     1.9.168.0      102.102.102.6   fffffff0 00002710 b500 0.0.0.0
6     1807     1.3.226.0      192.85.0.3      fffffff0 000003e8 b500 0.0.0.0
7     1809     1.6.197.0      192.85.3.3      fffffff0 000003e8 b500 0.0.0.0
```

Displaying OSPF virtual neighbor information

To display OSPF virtual neighbor information, enter the **show ip ospf virtual-neighbor** command at any CLI level.

```
Brocade#show ip ospf virtual-neighbor
```

Syntax: `show ip ospf virtual-neighbor [<num>]`

The *<num>* parameter displays the table beginning at the specified entry number.

Displaying OSPF virtual link information

To display OSPF virtual link information, enter the **show ip ospf virtual-link** command at any CLI level.

```
Brocade#show ip ospf virtual-link
```

Syntax: **show ip ospf virtual-link** [*<num>*]

The *<num>* parameter displays the table beginning at the specified entry number.

Displaying OSPF ABR and ASBR information

To display OSPF ABR and ASBR information, enter the **show ip ospf border-routers** command at any CLI level.

```
Brocade#show ip ospf border-routers
```

Syntax: **show ip ospf border-routers** [*<ip-addr>*]

The *<ip-addr>* parameter displays the ABR and ASBR entries for the specified IP address.

Displaying OSPF trap status

All traps are enabled by default when you enable OSPF. To disable or re-enable an OSPF trap, refer to [“Modifying OSPF traps generated”](#) on page 1266.

To display the state of each OSPF trap, enter the **show ip ospf trap** command at any CLI level.

```
Brocade#show ip ospf trap
Interface State Change Trap:           Enabled
Virtual Interface State Change Trap:    Enabled
Neighbor State Change Trap:            Enabled
Virtual Neighbor State Change Trap:     Enabled
Interface Configuration Error Trap:     Enabled
Virtual Interface Configuration Error Trap: Enabled
Interface Authentication Failure Trap:  Enabled
Virtual Interface Authentication Failure Trap: Enabled
Interface Receive Bad Packet Trap:      Enabled
Virtual Interface Receive Bad Packet Trap: Enabled
Interface Retransmit Packet Trap:       Enabled
Virtual Interface Retransmit Packet Trap: Enabled
Originate LSA Trap:                    Enabled
Originate MaxAge LSA Trap:             Enabled
Link State Database Overflow Trap:      Enabled
Link State Database Approaching Overflow Trap: Enabled
```

Syntax: **show ip ospf trap**

Displaying OSPF graceful restart information

To display OSPF graceful restart information for OSPF neighbors, use the **show ip ospf neighbors** command.

```
Brocade#show ip ospf neighbors
Port Address Pri State Neigh Address Neigh ID Ev Opt Cnt
2/7 50.50.50.10 0 FULL/OTHER 50.50.50.1 10.10.10.30 21 66 0
< in graceful restart state, helping 1, timer 60 sec >
```

Syntax: show ip ospf neighbor

Use the following command to display Type 9 grace LSAs on a Brocade Layer 3 switch.

```
Brocade#show ip ospf database grace-link-state
Graceful Link States
Area Interface Adv Rtr Age Seq(Hex) Prd Rsn Nbr Intf IP
0 eth 1/2 2.2.2.2 7 80000001 60 SW 6.1.1.2
```

Syntax: show ip ospf database grace-link-state

[Table 218](#) defines the fields in the show output.

TABLE 218 CLI display of OSPF database grace LSA information

Field	Definition
Area	The OSPF area that the interface configured for OSPF graceful restart is in.
Interface	The interface that is configured for OSPF graceful restart.
Adv Rtr	The ID of the advertised route.
Age	The age of the LSA in seconds.
Seq (Hex)	The sequence number of the LSA. The OSPF neighbor that sent the LSA stamps the LSA with a sequence number. This number enables the FastIron and other OSPF routers to determine the most recent LSA for a given route.
Prd	The grace period. The number of seconds that the neighbor routers should continue to advertise the router as fully adjacent, regardless of the state of database synchronization between the router and its neighbors. Since this time period begins when the grace LSA LS age is equal to 0, the grace period terminates when either the LS age of the grace LSA exceeds the value of a grace period or the grace LSA is flushed.
Rsn	The reason for the graceful restart. Possible values: <ul style="list-style-type: none"> • UK – Unknown • RS – Software restart • UP – Software upgrade or reload • SW – Switch to redundant control processor
Nbr Intf IP	The IP address of the OSPF graceful restart neighbor.

Displaying OSPF information

OSPF version 3 (IPv6)

Table 219 lists the individual Brocade FastIron switches and the Open Shortest Path First (OSPF) version 3 (IPv6) features they support. These features are supported with premium IPv6 devices running the full Layer 3 software image.

TABLE 219 Supported OSPF V3 features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6450
OSPF V3	Yes	No	Yes	Yes	No
Assigning OSPF V3 areas	Yes	No	Yes	Yes	No
Assigning interfaces to an area	Yes	No	Yes	Yes	No
Virtual links	Yes	No	Yes	Yes	No
Changing the reference bandwidth	Yes	No	Yes	Yes	No
Redistributing routes into OSPF V3	Yes	No	Yes	Yes	No
Filtering OSPF V3 routes	Yes	No	Yes	Yes	No
Configuring default route origination	Yes	No	Yes	Yes	No
Modifying SPF timers	Yes	No	Yes	Yes	No

OSPF (IPv6) overview

Open Shortest Path First (OSPF) is a link-state routing protocol. OSPF uses link-state advertisements (LSAs) to update neighboring routers about its interfaces and information on those interfaces. The switch floods LSAs to all neighboring routers to update them about the interfaces. Each router maintains an identical database that describes its area topology to help a router determine the shortest path between it and any neighboring router:

- The differences between OSPF Version 2 (OSPF V2) and OSPF Version 3 (OSPF V3).
- The link state advertisement types for OSPF Version 3.

- How to configure OSPF Version 3.
- How to display OSPF Version 3 information and statistics.

NOTE

The terms *Layer 3 Switch* and *router* are used interchangeably in this chapter and mean the same thing.

Differences between OSPF V2 and OSPF V3

IPv6 supports OSPF V3 functions similarly to OSPF V2 (the current version that IPv4 supports), except for the following enhancements:

- Support for IPv6 addresses and prefixes.
- While OSPF V2 runs per IP subnet, OSPF V3 runs per link. In general, you can configure several IPv6 addresses on a router interface, but OSPF V3 forms one adjacency per interface only, using the interface associated link-local address as the source for OSPF protocol packets. On virtual links, OSPF V3 uses the global IP address as the source.
- You can run one instance of OSPF Version 2 and one instance of OSPF V3 concurrently on a link.
- Support for IPv6 link state advertisements (LSAs).

In addition, Brocade implements some new commands that are specific to OSPF V3. This chapter describes the commands that are specific to OSPF V3.

NOTE

Although OSPF Versions 2 and 3 function similarly to each other, Brocade has implemented the user interface for each version independently of each other. Therefore, any configuration of OSPF Version 2 features will not affect the configuration of OSPF V3 features and vice versa.

NOTE

You are required to configure a router ID when running only IPv6 routing protocols.

Link state advertisement types for OSPF V3

OSPF V3 supports the following types of LSAs:

- Router LSAs (Type 1)
- Network LSAs (Type 2)
- Interarea-prefix LSAs for ABRs (Type 3)
- Interarea-router LSAs for ASBRs (Type 4)
- Autonomous system external LSAs (Type 5)
- Link LSAs (Type 8)
- Intra-area prefix LSAs (Type 9)

For more information about these LSAs, see RFC 2740.

OSPF V3 configuration

To configure OSPF V3, you must perform the following tasks:

1. [“Enabling OSPF V3”](#) on page 1289
2. [“Assigning OSPF V3 areas”](#) on page 1290
3. [“Assigning interfaces to an area”](#) on page 1291

The following configuration tasks are optional:

- Configure a virtual link between an ABR without a physical connection to a backbone area and the Brocade device in the same area with a physical connection to the backbone area.
- Change the reference bandwidth for the cost on OSPF V3 interfaces.
- Configure the redistribution of routes into OSPF V3.
- Configure default route origination.
- Modify the shortest path first (SPF) timers.
- Modify the administrative distances for OSPF V3 routes.
- Configure the OSPF V3 LSA pacing interval
- Modify how often the Brocade device checks on the elimination of the database overflow condition.
- Modify the external link state database limit.
- Modify the default values of OSPF V3 parameters for router interfaces.
- Disable or re-enable OSPF V3 event logging.

Enabling OSPF V3

Before enabling the Brocade device to run OSPF V3, you must do the following:

- Enable the forwarding of IPv6 traffic on the Brocade device using the **ipv6 unicast-routing** command.
- Enable IPv6 on each interface over which you plan to enable OSPF V3. You enable IPv6 on an interface by configuring an IPv6 address or explicitly enabling IPv6 on that interface.

By default, OSPF V3 is disabled. To enable OSPF V3, you must enable it globally.

To enable OSPF V3 globally, enter the **ipv6 router ospf** command.

```
Brocade(config-ospf-router)#ipv6 router ospf
Brocade(config-ospf6-router)#
```

After you enter this command, the Brocade device enters the IPv6 OSPF configuration level, where you can access several commands that allow you to configure OSPF V3.

Syntax: **[no] ipv6 router ospf**

To disable OSPF V3, enter the **no** form of this command. If you disable OSPF V3, the Brocade device removes all the configuration information for the disabled protocol from the running-config. Moreover, when you save the configuration to the startup-config file after disabling one of these protocols, all the configuration information for the disabled protocol is removed from the startup-config file.

The CLI displays a warning message such as the following.

```
Brocade(config-ospf6-router)#no ipv6 router ospf
ipv6 router ospf mode now disabled. All ospf config data will be lost when writing
to flash!
```

If you have disabled the protocol but have not yet saved the configuration to the startup-config file and reloaded the software, you can restore the configuration information by re-entering the command to enable the protocol (for example, **ipv6 router ospf**). If you have already saved the configuration to the startup-config file and reloaded the software, the information is gone. If you are testing an OSPF configuration and are likely to disable and re-enable the protocol, you might want to make a backup copy of the startup-config file containing the protocol configuration information. This way, if you remove the configuration information by saving the configuration after disabling the protocol, you can restore the configuration by copying the backup copy of the startup-config file onto the flash memory.

Assigning OSPF V3 areas

After OSPF V3 is enabled, you can assign OSPF V3 areas. You can assign an IPv4 address or a number as the **area ID** for each area. The area ID is representative of all IPv6 addresses (subnets) on a router interface. Each router interface can support one area.

An area can be **normal** or a **stub**:

- **Normal** – OSPF routers within a normal area can send and receive External Link State Advertisements (LSAs).
- **Stub** – OSPF routers within a stub area cannot send or receive External LSAs. In addition, OSPF routers in a stub area must use a default route to the area Area Border Router (ABR) or Autonomous System Boundary Router (ASBR) to send traffic out of the area.

For example, to set up OSPF V3 areas 0.0.0.0, 200.5.0.0, 192.5.1.0, and 195.5.0.0, enter the following commands.

```
Brocade(config-ospf6-router)#area 0.0.0.0
Brocade(config-ospf6-router)#area 200.5.0.0
Brocade(config-ospf6-router)#area 192.5.1.0
Brocade(config-ospf6-router)#area 195.5.0.0
```

Syntax: [no] **area** <number> | <ipv4-address>

The <number> | <ipv4-address> parameter specifies the area number, which can be a number or in IPv4 address format. If you specify a number, the number can be from 0 – 18.

NOTE

You can assign one area on a router interface.

Assigning a totally stubby area

By default, the Brocade device sends summary LSAs (LSA type 3) into stub areas. You can further reduce the number of LSAs sent into a stub area by configuring the Brocade device to stop sending summary LSAs into the area. You can disable the summary LSAs when you are configuring the stub area or later after you have configured the area.

This feature disables origination of summary LSAs into a stub area, but the Brocade device still accepts summary LSAs from OSPF neighbors and floods them to other areas. The Brocade device can form adjacencies with other routers regardless of whether summarization is enabled or disabled for areas on each router.

When you disable the summary LSAs, the change takes effect immediately. If you apply the option to a previously configured area, the router flushes all of the summary LSAs it has generated (as an ABR) from the area.

NOTE

This feature applies only when the Brocade device is configured as an Area Border Router (ABR) for the area. To completely prevent summary LSAs from being sent to the area, disable the summary LSAs on each OSPF router that is an ABR for the area.

For example, to disable summary LSAs for stub area 40 and specify an additional metric of 99, enter the following command.

```
Brocade(config-ospf6-router)#area 40 stub 99 no-summary
```

Syntax: **area** <number> | <ipv4-address> **stub** <metric> [**no-summary**]

The <number> | <ipv4-address> parameter specifies the area number, which can be a number or in IPv4 address format. If you specify a number, the number can be from 0 – 18.

The **stub** <metric> parameter specifies an additional cost for using a route to or from this area and can be from 1 – 16777215. There is no default. Normal areas do not use the cost parameter.

The **no-summary** parameter applies only to stub areas and disables summary LSAs from being sent into the area.

Assigning interfaces to an area

After you define OSPF V3 areas, you must assign router interfaces to the areas. All router interfaces must be assigned to one of the defined areas on an OSPF router. When an interface is assigned to an area, all corresponding subnets on that interface are automatically included in the assignment.

For example, to assign Ethernet interface 3/1 to area 192.5.0.0, enter the following commands.

```
Brocade(config)#interface ethernet 3/1
Brocade(config-if-e100-3/1)#ipv6 ospf area 192.5.0.0
```

Syntax: [**no**] **ipv6 ospf area** <number> | <ipv4-address>

The <number> | <ipv4-address> parameter specifies the area number, which can be a number or in IPv4 address format. If you specify a number, the number can be from 0 – 18.

To remove the interface from the specified area, use the **no** form of this command.

Configuring virtual links

All ABRs must have either a direct or indirect link to an OSPF backbone area (0.0.0.0 or 0). If an ABR does not have a physical link to a backbone area, you can configure a virtual link from the ABR to another router within the same area that has a physical connection to the backbone area.

The path for a virtual link is through an area shared by the neighbor ABR (router with a physical backbone connection) and the ABR requiring a logical connection to the backbone.

Two parameters must be defined for all virtual links—transit area ID and neighbor router:

- The transit area ID represents the shared area of the two ABRs and serves as the connection point between the two routers. This number should match the area ID value.
- When assigned from the router interface requiring a logical connection, the neighbor router field is the router ID (IPv4 address) of the router that is physically connected to the backbone. When assigned from the router interface with the physical connection, the neighbor router is the router ID (IPv4) address of the router requiring a logical connection to the backbone.

NOTE

By default, the Brocade router ID is the IPv4 address configured on the lowest numbered loopback interface. If the Brocade device does not have a loopback interface, the default router ID is the lowest numbered IPv4 address configured on the device.

NOTE

When you establish an area virtual link, you must configure it on both of the routers (both ends of the virtual link).

For example, imagine that ABR1 in areas 1 and 2 is cut off from the backbone area (area 0). To provide backbone access to ABR1, you can add a virtual link between ABR1 and ABR2 in area 1 using area 1 as a transit area. To configure the virtual link, you define the link on the router that is at each end of the link. No configuration for the virtual link is required on the routers in the transit area.

To define the virtual link on ABR1, enter the following command on ABR1.

```
Brocade(config-ospf6-router)#area 1 virtual-link 209.157.22.1
```

To define the virtual link on ABR2, enter the following command on ABR2.

```
Brocade(config-ospf6-router)#area 1 virtual-link 10.0.0.1
```

Syntax: **area** <number> | <ipv4-address> **virtual-link** <router-id>

The **area** <number> | <ipv4-address> parameter specifies the transit area.

The <router-id> parameter specifies the router ID of the OSPF router at the remote end of the virtual link. To display the router ID on a router, enter the **show ip** command.

Assigning a virtual link source address

When routers at both ends of a virtual link need to communicate with one another, the source address included in the packets must be a global IPv6 address. Therefore, you must determine the global IPv6 address to be used by the routers for communication across the virtual link. You can specify that a router uses the IPv6 global address assigned to one of its interfaces.

For example, to specify the global IPv6 address assigned to Ethernet interface 3/1 on ABR1 as the source address for the virtual link on ABR1, enter the following command on ABR1.

```
Brocade(config-ospf6-router)#virtual-link-if-address interface ethernet 3/1
```

To specify the global IPv6 address assigned to tunnel interface 1 on ABR2 as the source address for the virtual link on ABR2, enter the following command on ABR2.

```
Brocade(config-ospf6-router)#virtual-link-if-address interface tunnel 1
```

Syntax: **virtual-link-if-address interface ethernet** <port> | **loopback** <number> | **tunnel** <number> | **ve** <number>

The **ethernet** | **loopback** | **tunnel** | **ve** parameter specifies the interface from which the router derives the source IPv6 address for communication across the virtual link. If you specify an Ethernet interface, also specify the port number associated with the interface. If you specify a loopback, tunnel, or VE interface, also specify the number associated with the respective interface.

To delete the source address for the virtual link, use the **no** form of this command.

Modifying virtual link parameters

You can modify the following virtual link parameters:

- **Dead-interval:** The number of seconds that a neighbor router waits for a hello packet from the current router before declaring the router is down. The range is 1 – 65535 seconds. The default is 40 seconds.
- **Hello-interval:** The length of time between the transmission of hello packets. The range is 1 – 65535 seconds. The default is 10 seconds.
- **Retransmit-interval:** The interval between the re-transmission of link state advertisements to router adjacencies for this interface. The range is 0 – 3600 seconds. The default is 5 seconds.
- **Transmit-delay:** The period of time it takes to transmit Link State Update packets on the interface. The range is 0 – 3600 seconds. The default is 1 second.

NOTE

The values of the **dead-interval** and **hello-interval** parameters must be the same at both ends of a virtual link. Therefore, if you modify the values of these parameters at one end of a virtual link, you must remember to make the same modifications on the other end of the link.

The values of the other virtual link parameters do not require synchronization.

For example, to change the dead interval to 60 seconds on the virtual links defined on ABR1 and ABR2, enter the following command on ABR1.

```
Brocade(config-ospf6-router)#area 1 virtual-link 209.157.22.1
dead-interval 60
```

Enter the following command on ABR2.

```
Brocade(config-ospf6-router)#area 1 virtual-link 10.0.0.1 dead-interval 60
```

Syntax: **area** <number> | <ipv4-address> **virtual-link** <router-id> [**dead-interval** <seconds> | **hello-interval** <seconds> | **retransmit-interval** <seconds> | **transmit-delay** <seconds>]

The **area** <number> | <ipv4-address> parameter specifies the transit area.

The <router-id> parameter specifies the router ID of the OSPF router at the remote end of the virtual link. To display the router ID on a router, enter the **show ip** command.

The **dead-interval**, **hello-interval**, **retransmit-interval**, and **transmit-delay** parameters are discussed earlier in this section.

Changing the reference bandwidth for the cost on OSPF V3 interfaces

Each interface on which OSPF V3 is enabled has a cost associated with it. The Brocade device advertises its interfaces and their costs to OSPF V3 neighbors. For example, if an interface has an OSPF cost of ten, the Brocade device advertises the interface with a cost of ten to other OSPF routers.

By default, an interface OSPF cost is based on the port speed of the interface. The software uses the following formula to calculate the cost.

Cost = reference-bandwidth/interface-speed

By default, the reference bandwidth is 100 Mbps. If the resulting cost is less than 1, the software rounds the cost up to 1. The default reference bandwidth results in the following costs:

- 10 Mbps port cost = $100/10 = 10$
- 100 Mbps port cost = $100/100 = 1$
- 1000 Mbps port cost = $100/1000 = 0.10$, which is rounded up to 1
- 155 Mbps port cost = $100/155 = 0.65$, which is rounded up to 1
- 622 Mbps port cost = $100/622 = 0.16$, which is rounded up to 1
- 2488 Mbps port cost = $100/2488 = 0.04$, which is rounded up to 1

The bandwidth for interfaces that consist of more than one physical port is calculated as follows:

- **Trunk group** – The combined bandwidth of all the ports.
- **Virtual (Ethernet) interface** – The combined bandwidth of all the ports in the port-based VLAN that contains the virtual interface.

You can change the default reference bandwidth from 100 Mbps to a value from 1 – 4294967 Mbps.

If a change to the reference bandwidth results in a cost change to an interface, the Brocade device sends a link state update to update the costs of interfaces advertised by the Brocade device.

NOTE

If you specify the cost for an individual interface, the cost you specify overrides the cost calculated by the software.

Some interface types are not affected by the reference bandwidth and always have the same cost regardless of the reference bandwidth in use:

- The cost of a loopback interface is always 0.
- The cost of a virtual link is calculated using the Shortest Path First (SPF) algorithm and is not affected by the auto-cost feature.

For example, to change the reference bandwidth to 500, enter the following command.

```
Brocade(config-ospf6-router)#auto-cost reference-bandwidth 500
```

The reference bandwidth specified in this example results in the following costs:

- 10 Mbps port cost = $500/10 = 50$
- 100 Mbps port cost = $500/100 = 5$
- 1000 Mbps port cost = $500/1000 = 0.5$, which is rounded up to 1

- 155 Mbps port cost = $500/155 = 3.23$, which is rounded up to 4
- 622 Mbps port cost = $500/622 = 0.80$, which is rounded up to 1
- 2488 Mbps port cost = $500/2488 = 0.20$, which is rounded up to 1

The costs for 10 Mbps, 100 Mbps, and 155 Mbps ports change as a result of the changed reference bandwidth. Costs for higher-speed interfaces remain the same.

Syntax: `[no] auto-cost reference-bandwidth <number>`

The `<number>` parameter specifies the reference bandwidth and can be a value from 1 – 4294967. The default is 100.

To restore the reference bandwidth to its default value and thus restore the default costs of interfaces to their default values, enter the **no** form of this command.

Redistributing routes into OSPF V3

In addition to specifying which routes are redistributed into OSPF V3, you can configure the following aspects related to route redistribution:

- Default metric
- Metric type
- Advertisement of an external aggregate route

Configuring route redistribution into OSPF V3

You can configure the Brocade device to redistribute routes from the following sources into OSPF V3:

- IPv6 static routes
- Directly connected IPv6 networks
- RIPng

You can redistribute routes in the following ways:

- By route types, for example, the Brocade device redistributes all IPv6 static and RIPng routes.
- By using a route map to filter which routes to redistribute, for example, the Brocade device redistributes specified IPv6 static and RIPng routes only.

For example, to configure the redistribution of all IPv6 static RIPng routes, enter the following commands.

```
Brocade(config-ospf6-router)#redistribute static
Brocade(config-ospf6-router)#redistribute rip
```

Syntax: `no] redistribute bgp | connected | rip | static [metric <number> | metric-type <type>]`

The **connected** | **rip** | **static** keywords specify the route source.

The **metric <number>** parameter specifies the metric used for the redistributed route. If a value is not specified for this option, and the value for the **default-metric** command is set to 0, its default metric, then routes redistributed from the various routing protocols will have the metric value of the protocol from which they are redistributed. For information about the **default-metric** command, refer to [“Modifying default metric for routes redistributed into OSPF version 3”](#) on page 1297

The **metric-type** <type> parameter specifies an OSPF metric type for the redistributed route. You can specify external type 1 or external type 2. If a value is not specified for this option, the Brocade device uses the value specified by the **metric-type** command. For information about modifying the default metric type using the **metric-type** command, refer to [“Modifying default metric for routes redistributed into OSPF version 3”](#) on page 1297

For example, to configure a route map and use it for redistribution of routes into OSPF V3, enter commands such as the following.

```
Brocade(config)#ipv6 route 2001:1::/32 4823:eoff:343e::23
Brocade(config)#ipv6 route 2001:2::/32 4823:eoff:343e::23
Brocade(config)#ipv6 route 2001:3::/32 4823:eoff:343e::23 metric 5
Brocade(config)#route-map abc permit 1
Brocade(config-route-map abc)#match metric 5
Brocade(config-route-map abc)#set metric 8
Brocade(config-route-map abc)#ipv6 router ospf
Brocade(config-ospf6-router)#redistribute static route-map abc
```

The commands in this example configure some static IPv6 routes and a route map, and use the route map for redistributing the static IPv6 routes into OSPF V3.

The **ipv6 route** commands configure the static IPv6 routes.

The **route-map** command begins configuration of a route map called “abc”. The number indicates the route map entry (called the “instance”) you are configuring. A route map can contain multiple entries. The software compares packets to the route map entries in ascending numerical order and stops the comparison once a match is found.

NOTE

The default action rule for route-map is to deny all routes that are not explicitly permitted. Refer to [“Configuring an OSPF V3 distribution list using a route map that uses a prefix list”](#) on page 1301.

The **match** command in the route map matches on routes that have 5 for their metric value (cost). The **set** command changes the metric in routes that match the route map to 8.

The **redistribute** command configures the redistribution of static IPv6 routes into OSPF V3, and uses route map “abc” to control the routes that are redistributed. In this example, the route map allows a static IPv6 route to be redistributed into OSPF only if the route has a metric of 5, and changes the metric to 8 before placing the route into the OSPF route redistribution table.

Syntax: [no] redistribute bgp | connected | isis | rip | static [route-map <map-name>]

The **bgp** | **connected** | **isis** | **rip** | **static** keywords specify the route source.

The **route-map** <map-name> parameter specifies the route map name. The following match parameters are valid for OSPF V3 redistribution:

- **match metric** <number>

The following set parameters are valid for OSPF redistribution:

- **set metric** [+ | -] <number> | none
- **set metric-type** type-1 | type-2

NOTE

You must configure the route map before you configure a redistribution filter that uses the route map.

NOTE

When you use a route map for route redistribution, the software disregards the permit or deny action of the route map.

NOTE

For an external route that is redistributed into OSPF V3 through a route map, the metric value of the route remains the same unless the metric is set by a **set metric** command inside the route map or the **default-metric <num>** command. For a route redistributed without using a route map, the metric is set by the metric parameter if set or the **default-metric <num>** command if the metric parameter is not set.

Modifying default metric for routes redistributed into OSPF version 3

The default metric is a global parameter that specifies the cost applied by default to routes redistributed into OSPF V3. The default value is 0.

If the **metric** parameter for the **redistribute** command is not set and the **default-metric** command is set to 0, its default value, then routes redistributed from the various routing protocols will have the metric value of the protocol from which they are redistributed. For information about the **redistribute** command, refer to [“Configuring route redistribution into OSPF V3”](#) on page 1295.

NOTE

You also can define the cost on individual interfaces. The interface cost overrides the default cost. For information about defining the cost on individual interfaces, refer to [“Modifying OSPF V3 interface defaults”](#) on page 1306 and [“Changing the reference bandwidth for the cost on OSPF V3 interfaces”](#) on page 1294.

To assign a default metric of 4 to all routes imported into OSPF V3, enter the **default-metric** command.

```
Brocade(config-ospf6-router)#default-metric 4
```

Syntax: **no** | **default-metric** <number>

You can specify a value from 0 – 65535. The default is 0.

To restore the default metric to the default value, use the **no** form of this command.

Modifying metric type for routes redistributed into OSPF version 3

The Brocade device uses the **metric-type** parameter by default for all routes redistributed into OSPF V3 unless you specify a different metric type for individual routes using the **redistribute** command. (For more information about using the **redistribute** command, refer to [“Redistributing routes into OSPF V3”](#) on page 1295).

A type 1 route specifies a small metric (two bytes), while a type 2 route specifies a big metric (three bytes). The default value is type 2.

To modify the default value of type 2 to type 1, enter the **metric-type** command.

```
Brocade(config-ospf6-router)#metric-type type1
```

Syntax: **no** | **metric-type** type1 | type2

To restore the metric type to the default value, use the **no** form of this command.

External route summarization

When the Brocade device is an OSPF Autonomous System Boundary Router (ASBR), you can configure it to advertise one external route as an aggregate for all redistributed routes that are covered by a specified IPv6 address range.

When you configure an address range, the range takes effect immediately. All the imported routes are summarized according to the configured address range. Imported routes that have already been advertised and that fall within the range are flushed out of the AS and a single route corresponding to the range is advertised.

If a route that falls within a configured address range is imported by the Brocade device, no action is taken if the device has already advertised the aggregate route; otherwise, the device advertises the aggregate route. If an imported route that falls within a configured address range is removed by the device, no action is taken if there are other imported routes that fall within the same address range; otherwise the aggregate route is flushed.

You can configure up to 32 address ranges. The Brocade device sets the forwarding address of the aggregate route to zero and sets the tag to zero.

If you delete an address range, the advertised aggregate route is flushed and all imported routes that fall within the range are advertised individually.

If an external link state database overflow (LSDB) condition occurs, all aggregate routes are flushed out of the AS, along with other external routes. When the Brocade device exits the external LSDB overflow condition, all the imported routes are summarized according to the configured address ranges.

NOTE

If you use redistribution filters in addition to address ranges, the Brocade device applies the redistribution filters to routes first, then applies them to the address ranges.

NOTE

If you disable redistribution, all the aggregate routes are flushed, along with other imported routes.

NOTE

This option affects only imported, type 5 external routes. A single type 5 LSA is generated and flooded throughout the AS for multiple external routes.

Configuring external route summarization

To configure the summary address 2201::/24 for routes redistributed into OSPF V3, enter the following command.

```
Brocade(config-ospf6-router)#summary-address 2201::/24
```

In this example, the summary prefix 2201::/24 includes addresses 2201::/1 through 2201::/24. Only the address FEC0::/24 is advertised in an external link-state advertisement.

Syntax: `summary-address <ipv6-prefix>/<prefix-length>`

You must specify the `<ipv6-prefix>` parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

You must specify the `<prefix-length>` parameter as a decimal value. A slash mark (/) must follow the `<ipv6-prefix>` parameter and precede the `<prefix-length>` parameter.

Filtering OSPF V3 routes

You can filter the routes to be placed in the OSPF V3 route table by configuring distribution lists. OSPF V3 distribution lists can be applied globally or to an interface.

The functionality of OSPF V3 distribution lists is similar to that of OSPFv2 distribution lists. However, unlike OSPFv2 distribution lists, which filter routes based on criteria specified in an Access Control List (ACL), OSPF V3 distribution lists can filter routes using information specified in an IPv6 prefix list or a route map.

Configuration examples for filtering OSPF v3 routes

The following sections show examples of filtering OSPF V3 routes using prefix lists globally and for a specific interface, as well as filtering OSPF V3 routes using a route map.

You can configure the device to use all three types of filtering. When you do this, filtering using route maps has higher priority over filtering using global prefix lists. Filtering using prefix lists for a specific interface has lower priority than the other two filtering methods.

The example in this section assume the following routes are in the OSPF V3 route table.

```
Brocade#show ipv6 ospf route
```

```
Current Route count: 5

Configuring an OSPF V3 distribution list using an IPv6 prefix list as input

The following example illustrates how to use an IPv6 prefix list is used to filter OSPF V3 routes.

To specify an IPv6 prefix list called filterOspfRoutes that denies route 3010::/64, enter the following commands.

```
Brocade(config)#ipv6 prefix-list filterOspfRoutes seq 5 deny 3010::/64
Brocade(config)#ipv6 prefix-list filterOspfRoutes seq 7 permit ::/0 ge 1 le 128
```

Syntax: `ipv6 prefix-list <name> [seq <seq-value>] [description <string>] deny | permit <ipv6-addr>/<mask-bits> [ge <ge-value>] [le <le-value>]`

To configure a distribution list that applies the filterOspfRoutes prefix list globally.

```
Brocade(config)#ipv6 router ospf
Brocade(config-ospf6-router)#distribute-list prefix-list filterOspfRoutes in
```

Syntax: `[no] distribute-list prefix-list <name> in [<interface>]`

OSPF V3 configuration

After this distribution list is configured, route 3010::/64 would be omitted from the OSPF V3 route table.

```
Brocade#show ipv6 ospf route
```

```
Current Route count: 4
  Intra: 3 Inter: 0 External: 1 (Type1 0/Type2 1)
  Equal-cost multi-path: 0
  Destination          Options   Area          Cost Type2 Cost
  Next Hop Router      Outgoing Interface
*IA 3001::/64          -----  0.0.0.1         0  0
   ::                  ve 10
*IA 3015::/64          V6E---R-- 0.0.0.0        11  0
   fe80::2e0:52ff:fe00:10 ve 10
*IA 3020::/64          -----  0.0.0.0         10  0
   ::                  ve 11
*E2 6001:5000::/64     -----  0.0.0.0         10  0
   fe80::2e0:52ff:fe00:10 ve 10
```

The following commands specify an IPv6 prefix list called filterOspfRoutesVe that denies route 3015::/64.

```
Brocade(config)#ipv6 prefix-list filterOspfRoutesVe seq 5 deny 3015::/64
Brocade(config)#ipv6 prefix-list filterOspfRoutesVe seq 10 permit ::/0 ge 1 le 128
```

The following commands configure a distribution list that applies the filterOspfRoutesVe prefix list to routes pointing to virtual interface 10.

```
Brocade(config)#ipv6 router ospf
Brocade(config-ospf6-router)#distribute-list prefix-list filterOspfRoutes in ve
10
```

After this distribution list is configured, route 3015::/64, pointing to virtual interface 10, would be omitted from the OSPF V3 route table.

```
Brocade#show ipv6 ospf route
```

```
Current Route count: 4
  Intra: 3 Inter: 0 External: 1 (Type1 0/Type2 1)

   fe80::2e0:52ff:fe00:10 ve 10
```

Configuring an OSPF V3 distribution list using a route map as input

The following commands configure a route map that matches internal routes.

```
Brocade(config)#route-map allowInternalRoutes permit 10
Brocade(config-route-map allowInternalRoutes)#match route-type internal
```

Refer to “Policy-Based Routing” for information on configuring route maps.

The following commands configure a distribution list that applies the allowInternalRoutes route map globally to OSPF V3 routes.

```
Brocade(config)#ipv6 router ospf
Brocade(config-ospf6-router)#distribute-list route-map allowinternalroutes in
```

Syntax: [no] distribute-list route-map <name> in

After this distribution list is configured, the internal routes would be included, and the external routes would be omitted from the OSPF V3 route table.

```
Brocade#show ipv6 ospf route
```

```
Current Route count: 3
  Intra: 3 Inter: 0 External: 0 (Type1 0/Type2 0)
  Equal-cost multi-path: 0
  Destination          Options   Area          Cost Type2 Cost

*IA 3020::/64          -----  0.0.0.0          10 0
  ::                   ve 11
```

Configuring an OSPF V3 distribution list using a route map that uses a prefix list

When you configure route redistribution into OSPF V3 using a route map that uses a prefix list, the device supports both **permit** and **deny** statements in the route map and **permit** statements only in the prefix list. Therefore, the action to permit or deny is determined by the route map, and the conditions for the action are contained in the prefix list. The following shows an example configuration.

```
Brocade(config)#route-map v64 deny 10
Brocade(config-route-map v64)#match ipv6 next-hop prefix-list ospf-filter5
Brocade(config-route-map v64)#route-map v64 deny 11
Brocade(config-route-map v64)#match ipv6 address prefix-list ospf-filter2
Brocade(config-route-map v64)#route-map v64 permit 12
Brocade(config-route-map v64)#exit
Brocade(config)#ipv6 prefix-list ospf-filter2 seq 15 permit 2001:aa:2001:102::/64
ge 65 le 96
Brocade(config)#ipv6 prefix-list ospf-filter5 seq 15 permit
fe80::2e0:52ff:fe00:100/128
```

In this example the prefix lists, **ospf-filter2** and **ospf-filter5**, contain a range of IPv6 routes and one host route to be denied, and the route map **v64** defines the deny action.

NOTE

The default action rule for **route-map** is to deny all routes that are not explicitly permitted. If you configure a “deny” route map but want to permit other routes that do not match the rule, configure an “empty” permit route map. For example.

```
Brocade(config)#route-map abc deny 10
Brocade(config-route-map abc)#match metric 20
Brocade(config-route-map abc)#route-map abc permit 20
```

Without the last line in the above example, all routes would be denied.

Default route origination

When the Brocade device is an OSPF Autonomous System Boundary Router (ASBR), you can configure it to automatically generate a default external route into an OSPF V3 routing domain. This feature is called “default route origination” or “default information origination.”

By default, the Brocade device does not advertise the default route into the OSPF V3 domain. If you want the device to advertise the OSPF default route, you must explicitly enable default route origination.

When you enable OSPF default route origination, the device advertises a type 5 default route that is flooded throughout the AS (except stub areas).

The device advertises the default route into OSPF even if OSPF route redistribution is not enabled, and even if the default route is learned through an IBGP neighbor.

NOTE

The Brocade device does not advertise the OSPF default route, regardless of other configuration parameters, unless you explicitly enable default route origination.

If default route origination is enabled and you disable it, the default route originated by the device is flushed. Default routes generated by other OSPF routers are not affected. If you re-enable the feature, the feature takes effect immediately and thus does not require you to reload the software.

Configuring a default route origination

To create and advertise a default route with a metric of 2 and as a type 1 external route, enter the following command.

```
Brocade(config-ospf6-router)#default-information-originate always metric 2
metric-type type1
```

Syntax: [no] **default-information-originate** [always] [metric <value>] [metric-type <type>]

The **always** keyword originates a default route regardless of whether the device has learned a default route. This option is disabled by default.

The **metric <value>** parameter specifies a metric for the default route. If this option is not used, the value of the **default-metric** command is used for the route. For information about this command, refer to [“Modifying default metric for routes redistributed into OSPF version 3”](#) on page 1297

The **metric-type** <type> parameter specifies the external link type associated with the default route advertised into the OSPF routing domain. The <type> can be one of the following:

- 1 – Type 1 external route
- 2 – Type 2 external route

If you do not use this option, the default redistribution metric type is used for the route type.

NOTE

If you specify a metric and metric type, the values you specify are used even if you do not use the always option.

To disable default route origination, enter the **no** form of the command.

Shortest path first timers

The Brocade device uses the following timers when calculating the shortest path for OSPF V3 routes:

- **SPF delay** – When the Brocade device receives a topology change, the software waits before it starts a Shortest Path First (SPF) calculation. By default, the software waits 5 seconds. You can configure the SPF delay to a value from 0 – 65535 seconds. If you set the SPF delay to 0 seconds, the software immediately begins the SPF calculation after receiving a topology change.
- **SPF hold time** – The Brocade device waits a specific amount of time between consecutive SPF calculations. By default, the device waits 10 seconds. You can configure the SPF hold time to a value from 0 – 65535 seconds. If you set the SPF hold time to 0 seconds, the software does not wait between consecutive SPF calculations.

You can set the SPF delay and hold time to lower values to cause the device to change to alternate paths more quickly if a route fails. Note that lower values for these parameters require more CPU processing time.

You can change one or both of the timers.

NOTE

If you want to change only one of the timers, for example, the SPF delay timer, you must specify the new value for this timer as well as the current value of the SPF hold timer, which you want to retain. The Brocade device does not accept only one timer value.

Modifying shortest path first timers

To change the SPF delay to 10 seconds and the SPF hold to 20 seconds, enter the following command.

```
Brocade(config-ospf6-router)#timers spf 10 20
```

Syntax: **timers spf** <delay> <hold-time>

For the <delay> and <hold-time> parameters, specify a value from 0 – 65535 seconds.

To set the timers back to their default values, enter the **no** version of this command.

Administrative distance

The Brocade device can learn about networks from various protocols, including IPv6, RIPng, and OSPF V3. Consequently, the routes to a network may differ depending on the protocol from which the routes were learned. By default, the administrative distance for OSPF V3 routes is 110.

The device selects one route over another based on the source of the route information. To do so, the device can use the administrative distances assigned to the sources. You can influence the device decision by changing the default administrative distance for OSPF V3 routes.

Configuring administrative distance based on route type

You can configure a unique administrative distance for each type of OSPF V3 route. For example, you can use this feature to influence the Brocade device to prefer a static route over an OSPF inter-area route and to prefer OSPF intra-area routes to static routes.

The distance you specify influences the choice of routes when the device has multiple routes to the same network from different protocols. The device prefers the route with the lower administrative distance.

You can specify unique default administrative distances for the following OSPF V3 route types:

- Intra-area routes
- Inter-area routes
- External routes

The default for all of these OSPF V3 route types is 110.

NOTE

This feature does not influence the choice of routes within OSPF V3. For example, an OSPF intra-area route is always preferred over an OSPF inter-area route, even if the intra-area route distance is greater than the inter-area route distance.

For example, to change the default administrative distances for intra-area routes to 80, inter-area routes to 90, and external routes to 100, enter the following commands.

```
Brocade(config-ospf6-router)#distance intra-area 80
Brocade(config-ospf6-router)#distance inter-area 90
Brocade(config-ospf6-router)#distance external 100
```

Syntax: `distance external | inter-area | intra-area <distance>`

The **external | inter-area | intra-area** keywords specify the route type for which you are changing the default administrative distance.

The **<distance>** parameter specifies the new distance for the specified route type. You can specify a value from 1 – 255.

To reset the administrative distance of a route type to its system default, enter the **no** form of this command.

Configuring the OSPF V3 LSA pacing interval

The Brocade device paces OSPF V3 LSA refreshes by delaying the refreshes for a specified time interval instead of performing a refresh each time an individual LSA refresh timer expires. The accumulated LSAs constitute a group, which the Brocade device refreshes and sends out together in one or more packets.

The pacing interval, which is the interval at which the Brocade device refreshes an accumulated group of LSAs, is configurable to a range from 10 – 1800 seconds (30 minutes). The default is 240 seconds (four minutes). Thus, every four minutes, the Brocade device refreshes the group of accumulated LSAs and sends the group together in the same packets.

The pacing interval is inversely proportional to the number of LSAs the Brocade device is refreshing and aging. For example, if you have approximately 10,000 LSAs, decreasing the pacing interval enhances performance. If you have a very small database (40 – 100 LSAs), increasing the pacing interval to 10 – 20 minutes might enhance performance only slightly.

To change the OSPF V3 LSA pacing interval to two minutes (120 seconds), enter the following command.

```
Brocade(config)#ipv6 router ospf
Brocade(config-ospf6-router)#timers lsa-group-pacing 120
```

Syntax: [no] **timers lsa-group-pacing** <seconds>

The <seconds> parameter specifies the number of seconds and can be from 10 – 1800 (30 minutes). The default is 240 seconds (four minutes).

To restore the pacing interval to its default value, use the **no** form of the command.

Modifying exit overflow interval

If a database overflow condition occurs on the Brocade device, the device eliminates the condition by removing entries that originated on the device. The exit overflow interval allows you to set how often a device checks to see if the overflow condition has been eliminated. The default value is 0. If the configured value of the database overflow interval is 0, then the device never leaves the database overflow condition.

For example, to modify the exit overflow interval to 60 seconds, enter the following command.

```
Brocade(config-ospf6-router)#database-overflow-interval 60
```

Syntax: [no] **auto-cost reference-bandwidth** <number>

The <seconds> parameter can be a value from 0 – 86400 seconds (24 hours).

To reset the exit overflow interval to its system default, enter the **no** form of this command.

Modifying external link state database limit

By default, the link state database can hold a maximum of 2000 entries for external (type 5) LSAs. You can change the maximum number of entries from 500 – 8000. After changing this limit, make sure to save the running-config file and reload the software. The change does not take effect until you reload or reboot the software.

For example, to change the maximum number entries from the default of 2000 to 3000, enter the following command.

```
Brocade(config-ospf6-router)#external-lsdb-limit 3000
```

Syntax: `ipv6 ospf area <number> | <ipv4-address>`

The `<entries>` parameter can be a numerical value from 500 – 8000 seconds.

To reset the maximum number of entries to its system default, enter the **no** form of this command.

Modifying OSPF V3 interface defaults

OSPF V3 has interface parameters that you can configure. For simplicity, each of these parameters has a default value. No change to these default values is required except as needed for specific network configurations.

You can modify the default values for the following OSPF interface parameters:

- **Cost:** Indicates the overhead required to send a packet across an interface. You can modify the cost to differentiate between 100 Mbps and 1000 Mbps (1 Gbps) links. The command syntax is `ipv6 ospf cost <number>`. The default cost is calculated by dividing 100 million by the bandwidth. For 10 Mbps links, the cost is 10. The cost for both 100 Mbps and 1000 Mbps links is 1, because the speed of 1000 Mbps was not in use at the time the OSPF cost formula was devised.
- **Dead-interval:** Indicates the number of seconds that a neighbor router waits for a hello packet from the current router before declaring the router down. The command syntax is `ipv6 ospf dead-interval <seconds>`. The value can be from 1 – 2147483647 seconds. The default is 40 seconds.
- **Hello-interval:** Represents the length of time between the transmission of hello packets. The command syntax is `ipv6 ospf hello-interval <seconds>`. The value can be from 1 – 65535 seconds. The default is 10 seconds.
- **Instance:** Indicates the number of OSPF V3 instances running on an interface. The command syntax is `ipv6 ospf instance <number>`. The value can be from 0 – 255. The default is 1.
- **MTU-ignore:** Allows you to disable a check that verifies the same MTU is used on an interface shared by neighbors. The command syntax is `ipv6 ospf mtu-ignore`. By default, the mismatch detection is enabled.
- **Network:** Allows you to configure the OSPF network type. The command syntax is `ipv6 ospf network [point-to-multipoint]`. The default setting of the parameter depends on the network type.
- **Passive:** When you configure an OSPF interface to be passive, that interface does not send or receive OSPF route updates. This option affects all IPv6 subnets configured on the interface. The command syntax is `ipv6 ospf passive`. By default, all OSPF interfaces are active and thus can send and receive OSPF route information. Since a passive interface does not send or receive route information, the interface is in effect a stub network.
- **Priority:** Allows you to modify the priority of an OSPF router. The priority is used when selecting the designated router (DR) and backup designated routers (BDRs). The command syntax is `ipv6 ospf priority <number>`. The value can be from 0 – 255. The default is 1. If you set the priority to 0, the router does not participate in DR and BDR election.
- **Retransmit-interval:** The time between retransmissions of LSAs to adjacent routers for an interface. The command syntax is `ipv6 ospf retransmit-interval <seconds>`. The value can be from 0 – 3600 seconds. The default is 5 seconds.

- **Transmit-delay:** The time it takes to transmit Link State Update packets on this interface. The command syntax is **ipv6 ospf transmit-delay <seconds>**. The value can be from 0 – 3600 seconds. The default is 1 second.

Disabling or re-enabling event logging

OSPF V3 does not currently support the generation of SNMP traps. Instead, you can disable or re-enable the logging of OSPF V3-related events such as neighbor state changes and database overflow conditions. By default, the Brocade device logs these events.

To disable the logging of events, enter the following command.

```
Brocade(config-ospf6-router)#no log-status-change
```

Syntax: [no] log-status-change

To re-enable the logging of events, enter the following command.

```
Brocade(config-ospf6-router)#log-status-change
```

IPSec for OSPFv3

This section describes the implementation of Internet Protocol Security (IPSec) for securing OSPFv3 traffic. For background information and configuration steps, refer to [“IPsec for OSPFv3 configuration”](#) on page 1308.

IPsec is available for OSPFv3 traffic only and only for packets that are “for-us.” A for-us packet is addressed to one of the IPv6 addresses on the device or to an IPv6 multicast address. Packets that are just forwarded by the line card do not receive IPsec scrutiny.

Brocade devices support the following components of IPsec for IPv6-addressed packets:

- Authentication through Encapsulating Security Payload (ESP) in transport mode
- HMAC-SHA1-96 as the authentication algorithm
- Manual configuration of keys
- Configurable rollover timer

IPsec can be enabled on the following logical entities:

- Interface
- Area
- Virtual link

With respect to traffic classes, this implementation of IPsec uses a single security association (SA) between the source and destination to support all traffic classes and so does not differentiate between the different classes of traffic that the DSCP bits define.

Instructions for configuring IPsec on these entities appear in [“IPsec for OSPFv3 configuration”](#) on page 1308.

IPsec on a virtual link is a global configuration. Interface and area IPsec configurations are more granular.

Among the entities that can have IPsec protection, the interfaces and areas can overlap. The interface IPsec configuration takes precedence over the area IPsec configuration when an area and an interface within that area use IPsec. Therefore, if you configure IPsec for an interface and an area configuration also exists that includes this interface, the interface's IPsec configuration is used by that interface. However, if you disable IPsec on an interface, IPsec is disabled on the interface even if the interface has its own, specific authentication. Refer to [“Disabling IPsec on an interface”](#) on page 1313.

For IPsec, the system generates two types of databases. The *security association database* (SAD) contains a security association for each interface or one global database for a virtual link. Even if IPsec is configured for an area, each interface that uses the area's IPsec still has its own security association in the SAD. Each SA in the SAD is a generated entry that is based on your specifications of an authentication protocol (ESP in the current release), destination address, and a security policy index (SPI). The SPI number is user-specified according to the network plan. Consideration for the SPI values to specify must apply to the whole network.

The system-generated security policy databases (SPDs) contain the security policies against which the system checks the for-us packets. For each for-us packet that has an ESP header, the applicable security policy in the security policy database (SPD) is checked to see if this packet complies with the policy. The IPsec task drops the non-compliant packets. Compliant packets continue on to the OSPFv3 module.

IPsec for OSPFv3 configuration

This section describes how to configure IPsec for an interface, area, and virtual link. It also describes how to change the key rollover timer if necessary and how to disable IPsec on a particular interface for special purposes.

By default, OSPFv3 IPsec authentication is disabled. The following IPsec parameters are configurable:

- ESP security protocol
- Authentication
- HMAC-SHA1-96 authentication algorithm
- Security parameter index (SPI)
- A 40-character key using hexadecimal characters
- An option for not encrypting the keyword when it appears in **show** command output
- Key rollover timer

NOTE

In the current release, certain keyword parameters must be entered even though only one keyword choice is possible for that parameter. For example, the only authentication algorithm in the current release is HMAC-SHA1-96, but you must nevertheless enter the keyword for this algorithm. Also, ESP currently is the only authentication protocol, but you must still enter the **esp** keyword. This section describes all keywords.

General considerations when configuring IPsec for OSPFv3

The IPsec component generates security associations and security policies based on certain user-specified parameters. The parameters are described with the syntax of each command in this section and also pointed out in the section with the **show** command examples, [“IPsec examples”](#) on page 1334. User-specified parameters and their relation to system-generated values are as follows:

- **Security association:** based on your entries for *security policy index* (SPI), *destination address*, and *security protocol* (currently ESP), the system creates a security association for each interface or virtual link.
- **Security policy database:** based on your entries for SPI, *source address*, *destination addresses*, and *security protocol*, the system creates a security policy database for each interface or virtual link.
- You can configure the same SPI and key on multiple interfaces and areas, but they still have unique IPsec configurations because the SA and policies are added to each separate security policy database (SPD) that is associated with a particular interface. If you configure an SA with the same SPI in multiple places, the rest of the parameters associated with the SA—such as key, crypto algorithm, and security protocol, and so on—must match. If the system detects a mismatch, it displays an error message.
- IPsec authentication for OSPFv3 requires the use of multiple SPDs, one for each interface. A virtual link has a separate, global SPD. The authentication configuration on a virtual link must be different from the authentication configuration for an area or interface, as required by RFC4552. The interface number is used to generate a non-zero security policy database identifier (SPDID), but for the global SPD for a virtual link, the system-generated SPDID is always zero. As a hypothetical example, the SPD for interface eth 1/1 might have the system-generated SPDID of 1, and so on.
- If you change an existing key, you must also specify a different SPI value. For example, in an interface context where you intend to change a key, you must type a different SPI value—which occurs before the key parameter on the command line—before you type the new key. The example in [“IPsec for OSPFv3 configuration”](#) illustrates this requirement.
- The old key is active for twice the current configured key-rollover-interval for the inbound direction. In the outbound direction, the old key remains active for a duration equal to the key-rollover-interval. If the key-rollover-interval is set to 0, the new key immediately takes effect for both directions. For a description of the key-rollover-interval, refer to the [“Changing the key rollover timer”](#) on page 1313 section.

Interface and area IPsec considerations

This section describes the precedence of interface and area IPsec configurations.

If you configure an interface IPsec by using the **ipv6 ospf authentication** command in the context of a specific interface, that interface's IPsec configuration overrides the area configuration of IPsec.

If you configure IPsec for an area, all interfaces that utilize the area-wide IPsec (where interface-specific IPsec is not configured) nevertheless receive an SPD entry (and SPDID number) that is unique for the interface.

The area-wide SPI that you specify is a constant for all interfaces in the area that use the area IPsec, but the use of different interfaces results in an SPDID and an SA that are unique to each interface. (Recall from “IPsec for OSPFv3” on page 1307 that the security policy database depends partly on the source IP address, so a unique SPD for each interface results.)

Considerations for IPsec on virtual links

The IPsec configuration for a virtual link is global, so only one security association database and one security policy database exist for virtual links if you choose to configure IPsec for virtual links.

The virtual link IPsec SAs and policies are added to all interfaces of the transit area for the outbound direction. For the inbound direction, IPsec SAs and policies for virtual links are added to the global database.

NOTE

The security association (SA), security protocol index (SPI), security protocol database (SPD), and key have mutual dependencies, as the subsections that follow describe.

Specifying the key rollover timer

Configuration changes for authentication takes effect in a controlled manner through the key rollover procedure as specified in RFC 4552, Section 10.1. The key rollover timer controls the timing of the configuration changeover. The key rollover timer can be configured in the IPv6 router OSPF context, as the following example illustrates.

```
Brocade(config-ospf6-router)#key-rollover-interval 200
```

Syntax: `key-rollover-interval <time>`

The range for the key-rollover-interval is 0 – 14400 seconds. The default is 300 seconds.

Configuring IPsec on a interface

For IPsec to work, the IPsec configuration must be the same on all the routers to which an interface connects.

For multicast, IPsec does not need or use a specific destination address—the destination address is “do not care,” and this status is reflected by the lone pair of colons (::) for destination address in the **show** command output.

To configure IPsec on an interface, proceed as in the following example.

NOTE

The IPsec configuration for an interface applies to the inbound and outbound directions. Also, the same authentication parameters must be used by all routers on the network to which the interface is connected, as described in section 7 of RFC 4552.

```
Brocade(config-if-e10000-1/2)#ipv6 ospf auth ipsec spi 429496795 esp sha1
abcdef12345678900987654321fedcba12345678
```

Syntax: `[no] ipv6 ospf authentication ipsec spi <spinum> esp sha1 [no-encrypt] <key>`

The **no** form of this command deletes IPsec from the interface.

The **ipv6** command is available in the configuration interface context for a specific interface.

The **ospf** keyword identifies OSPFv3 as the protocol to receive IPsec security.

The **authentication** keyword enables authentication.

The **ipsec** keyword specifies IPsec as the authentication protocol.

The **spi** keyword and the *<spinum>* variable specify the security parameter that points to the security association. The near-end and far-end values for spinum must be the same. The range for *<spinum>* is decimal 256 – 4294967295.

The mandatory **esp** keyword specifies ESP (rather than authentication header) as the protocol to provide packet-level security. In the current release, this parameter can be **esp** only.

The **sha1** keyword specifies the HMAC-SHA1-96 authentication algorithm. This mandatory parameter can be only the **sha1** keyword in the current release.

Including the optional **no-encrypt** keyword means that when you display the IPsec configuration, the key is displayed in its unencrypted form and also saved as unencrypted.

The *<key>* variable must be 40 hexadecimal characters. To change an existing key, you must also specify a different SPI value. You cannot just change the key without also specifying a different SPI, too. For example, in an interface context where you intend to change a key, you must type a different SPI value—which occurs before the key parameter on the command line—before you type the new key. The example in [“IPsec for OSPFv3 configuration”](#) illustrates this requirement.

If **no-encrypt** is not entered, then the key will be encrypted. This is the default. The system adds the following in the configuration to indicate that the key is encrypted:

- **encrypt** = the key string uses proprietary simple cryptographic 2-way algorithm.
- **encryptb64** = the key string uses proprietary base64 cryptographic 2-way algorithm.

This example results in the configuration shown in the screen output that follows. Note that because the optional **no-encrypt** keyword was omitted, the display of the key has the encrypted form by default.

```
interface ethernet 1/1/2
  enable
  ip address 40.3.3.1/8
  ipv6 address 40:3:3::1/64
  ipv6 ospf area 1
  ipv6 ospf authentication ipsec spi 429496795 esp sha1 encryptb64
  $ITJkQG5HWnw4M09tWVd
```

Configuring IPsec for an area

This application of the **area** command (for IPsec) applies to all of the interfaces that belong to an area unless an interface has its own IPsec configuration. (As described in [“Disabling IPsec on an interface”](#) on page 1313, the interface IPsec can be operationally disabled if necessary.) To configure IPsec for an area in the IPv6 router OSPF context, proceed as in the following example.

```
Brocade(config-ospf6-router)#area 2 auth ipsec spi 400 esp sha1
abcef12345678901234fedcba098765432109876
```

Syntax: **area** *<area-id>* **authentication ipsec spi** *<spinum>* **esp sha1** [**no-encrypt**] *<key>*

The **no** form of this command deletes IPsec from the area.

The **area** command and the *<area-id>* variable specify the area for this IPsec configuration. The *<area-id>* can be an integer in the range 0 – 2,147,483,647 or have the format of an IP address.

The **authentication** keyword specifies that the function to specify for the area is packet authentication.

The **ipsec** keyword specifies that IPsec is the protocol that authenticates the packets.

The **spi** keyword and the *<spinum>* variable specify the index that points to the security association. The near-end and far-end values for spinum must be the same. The range for *<spinum>* is decimal 256 – 4294967295.

The mandatory **esp** keyword specifies ESP (rather than authentication header) as the protocol to provide packet-level security. In the current release, this parameter can be **esp** only.

The **sha1** keyword specifies the HMAC-SHA1-96 authentication algorithm. This mandatory parameter can be only the **sha1** keyword in the current release.

Including the optional **no-encrypt** keyword means that the 40-character key is not encrypted upon either its entry or its display. The key must be 40 hexadecimal characters.

If **no-encrypt** is not entered, then the key will be encrypted. This is the default. The system adds the following in the configuration to indicate that the key is encrypted:

- **encrypt** = the key string uses proprietary simple cryptographic 2-way algorithm.
- **encryptb64** = the key string uses proprietary base64 cryptographic 2-way algorithm.

The configuration in the preceding example results in the configuration for area 2 that is illustrated in the following example.

```
ipv6 router ospf
  area 0
  area 1
  area 2
  area 2 auth ipsec spi 400 esp sha1 abcef12345678901234fedcba098765432109876
```

Configuring IPsec for a virtual link

IPsec on a virtual link has a global configuration.

To configure IPsec on a virtual link, enter the IPv6 router OSPF context of the CLI and proceed as the following example illustrates. (Note the **no-encrypt** option in this example.)

```
Brocade(config-ospf6-router)#area 1 vir 2.2.2.2 auth ipsec spi 360 esp sha1
no-encrypt 1234567890098765432112345678990987654321
```

Syntax: **[no] area <area-id> virtual <nbrid> authentication ipsec spi <spinum> esp sha1**
[no-encrypt] <key>

The **no** form of this command deletes IPsec from the virtual link.

The **area** command and the *<area-id>* variable specify the area is to be configured. The *<area-id>* can be an integer in the range 0 – 2,147,483,647 or have the format of an IP address.

The **virtual** keyword indicates that this configuration applies to the virtual link identified by the subsequent variable *<nbrid>*. The variable *<nbrid>* is in dotted decimal notation of an IP address.

The **authentication** keyword specifies that the function to specify for the area is packet authentication.

The **ipsec** keyword specifies that IPsec is the protocol that authenticates the packets.

The **spi** keyword and the *<spinum>* variable specify the index that points to the security association. The near-end and far-end values for spinum must be the same. The range for *<spinum>* is decimal 256 – 4294967295.

The mandatory **esp** keyword specifies ESP (rather than authentication header) as the protocol to provide packet-level security. In the current release, this parameter can be **esp** only.

The **sha1** keyword specifies the HMAC-SHA1-96 authentication algorithm. This mandatory parameter can be only the **sha1** keyword in the current release.

Including the optional **no-encrypt** keyword means that the 40-character key is not encrypted in **show** command displays. If **no-encrypt** is not entered, then the key will be encrypted. This is the default. The system adds the following in the configuration to indicate that the key is encrypted:

- **encrypt** = the key string uses proprietary simple cryptographic 2-way algorithm.
- **encryptb64** = the key string uses proprietary base64 cryptographic 2-way algorithm.

This example results in the following configuration.

```
area 1 virtual-link 2.2.2.2
area 1 virtual-link 2.2.2.2 authentication ipsec spi 360 esp sha1 no-encrypt 12
34567890098765432112345678990987654321
```

Disabling IPsec on an interface

For the purpose of troubleshooting, you can operationally disable IPsec on an interface by using the **ipv6 ospf authentication ipsec disable** command in the CLI context of a specific interface. This command disables IPsec on the interface whether its IPsec configuration is the area's IPsec configuration or is specific to that interface. The output of the **show ipv6 ospf interface command** shows the current setting for the disable command.

To disable IPsec on an interface, go to the CLI context of the interface and proceed as in the following example.

```
Brocade(config-if-e10000-1/2)#ipv6 ospf auth ipsec disable
```

Syntax: **[no] ipv6 ospf authentication ipsec disable**

The **no** form of this command restores the area and interface-specific IPsec operation.

Changing the key rollover timer

Configuration changes for authentication takes effect in a controlled manner through the key rollover procedure as specified in RFC 4552, Section 10.1. The key rollover timer controls the timing of the configuration changeover. The key rollover timer can be configured in the IPv6 router OSPF context, as the following example illustrates.

```
Brocade(config-ospf6-router)#key-rollover-interval 200
```

Syntax: **key-rollover-interval <time>**

The range for the key-rollover-interval is 0 – 14400 seconds. The default is 300 seconds.

Clearing IPsec statistics

This section describes the **clear ipsec statistics** command for clearing statistics related to IPsec. The command resets to 0 the counters (which you can view as a part of IPsec Packet Statistics). The counters hold IPsec packet statistics and IPsec error statistics. The following example illustrates the **show ipsec statistics** output.

```
Brocade#show ipsec statistics
                        IPsec Statistics
secEspCurrentInboundSAs 1      ipsecEspTotalInboundSAs: 2
secEspCurrentOutboundSA 1      ipsecEspTotalOutboundSAs: 2
                        IPsec Packet Statistics
secEspTotalInPkts:      20      ipsecEspTotalInPktsDrop: 0
secEspTotalOutPkts:      84
                        IPsec Error Statistics
secAuthenticationErrors 0
secReplayErrors:      0      ipsecPolicyErrors:      13
secOtherReceiveErrors: 0      ipsecSendErrors:      0
secUnknownSpiErrors: 0
```

To clear the statistics, enter the **clear ipsec statistics** command as in the following example.

```
Brocade#clear ipsec statistics
```

Syntax: **clear ipsec statistics**

This command takes no parameters.

Displaying OSPF V3 Information

You can display the information for the following OSPF V3 parameters:

- Areas
- Link state databases
- Interfaces
- Memory usage
- Neighbors
- Redistributed routes
- Routes
- SPF
- Virtual links
- Virtual neighbors
- IPsec

Displaying OSPF V3 area information

To display global OSPF V3 area information for the Brocade device, enter the following command at any CLI level.

```
Brocade#show ipv6 ospf area
Area 0:
  Interface attached to this area: loopback 2 ethe 3/2 tunnel 2
  Number of Area scoped LSAs is 6
  Statistics of Area 0:
    SPF algorithm executed 16 times
    SPF last updated: 335256 sec ago
    Current SPF node count: 3
      Router: 2 Network: 1
    Maximum of Hop count to nodes: 2
...
```

Syntax: `show ipv6 ospf area [<area id>]`

You can specify the <area-id> parameter in the following formats:

- As an IPv4 address, for example, 192.168.1.1.
- As a numerical value from 0 – 2,147,483,647.

The <area-id> parameter restricts the display to the specified OSPF area.

This display shows the following information.

TABLE 220 OSPF V3 area information fields

Field	Description
Area	The area number.
Interface attached to this area	The router interfaces attached to the area.
Number of Area scoped LSAs	Number of LSAs with a scope of the specified area.
SPF algorithm executed	The number of times the OSPF Shortest Path First (SPF) algorithm is executed within the area.
SPF last updated	The interval in seconds that the SPF algorithm was last executed within the area.
Current SPF node count	The current number of SPF nodes in the area.
Router	Number of router LSAs in the area.
Network	Number of network LSAs in the area.
Indx	The row number of the entry in the router OSPF area table.
Area	The area number.
Maximum hop count to nodes.	The maximum number of hop counts to an SPF node within the area.

Displaying OSPF V3 database information

You can display a summary of the link state database or detailed information about a specified LSA type.

To display a summary of a device link state database, enter the **show ipv6 ospf database** command at any CLI level.

```
Brocade#show ipv6 ospf database
Area ID          Type LS ID      Adv Rtr          Seq(Hex) Age  Cksum  Len
0                Link 000001e6 223.223.223.223 800000ab 1547 8955 68
0                Link 000000d8 1.1.1.1         800000aa 1295 0639 68
0                Link 00000185 223.223.223.223 800000ab 1481 7e6b 56
0                Iap  00000077 223.223.223.223 800000aa 1404 966a 56
0                Rtr  00000124 223.223.223.223 800000b0 1397 912c 40
0                Net  00000016 223.223.223.223 800000aa 1388 1b09 32
0                Iap  000001d1 223.223.223.223 800000bd 1379 a072 72
0                Iap  000000c3 1.1.1.1         800000ae 1325 e021 52
0                Rtr  00000170 1.1.1.1         800000ad 1280 af8e 40
N/A              Extn 00000062 223.223.223.223 800000ae 1409 0ca7 32
N/A              Extn 0000021d 223.223.223.223 800000a8 1319 441e 32
```

Syntax: **show ipv6 ospf database** [**advrtr** <ipv4-address> | **as-external** | **extensive** | **inter-prefix** | **inter-router** | **intra-prefix** | **link** | **link-id** <number> | **network** | **router** [**scope** <area-id> | **as** | **link**]]

The **advrtr** <ipv4-address> parameter displays detailed information about the LSAs for a specified advertising router only.

The **as-external** keyword displays detailed information about the AS externals LSAs only.

The **extensive** keyword displays detailed information about all LSAs in the database.

The **inter-prefix** keyword displays detailed information about the inter-area prefix LSAs only.

The **inter-router** keyword displays detailed information about the inter-area router LSAs only.

The **intra-prefix** keyword displays detailed information about the intra-area prefix LSAs only.

The **link** keyword displays detailed information about the link LSAs only.

The **link-id** <number> parameter displays detailed information about the specified link LSAs only.

The **network** <number> displays detailed information about the network LSAs only.

The **router** <number> displays detailed information about the router LSAs only.

The **scope** <area-id> parameter displays detailed information about the LSAs for a specified area, AS, or link.

This display shows the following information.

TABLE 221 OSPF V3 database summary fields

Field	Description
Area ID	The OSPF area in which the Brocade device resides.
Type	Type of LSA. LSA types can be the following: <ul style="list-style-type: none"> • Rtr – Router LSAs (Type 1). • Net – Network LSAs (Type 2). • Inap – Inter-area prefix LSAs for ABRs (Type 3). • Inar – Inter-area router LSAs for ASBRs (Type 4). • Extn – AS external LSAs (Type 5). • Link – Link LSAs (Type 8). • lap – Intra-area prefix LSAs (Type 9).
LS ID	The ID of the LSA, in hexadecimal, from which the device learned this route.
Adv Rtr	The device that advertised the route.
Seq(Hex)	The sequence number of the LSA. The OSPF neighbor that sent the LSA stamps it with a sequence number to enable the Brocade device and other OSPF routers to determine which LSA for a given route is the most recent.
Age	The age of the LSA, in seconds.
Chksum	A checksum for the LSA packet. The checksum is based on all the fields in the packet except the age field. The Brocade device uses the checksum to verify that the packet is not corrupted.
Len	The length, in bytes, of the LSA.

For example, to display detailed information about all LSAs in the database, enter the **show ipv6 ospf database extensive** command at any CLI level.

Displaying OSPF V3 Information

NOTE

Portions of this display are truncated for brevity. The purpose of this display is to show all possible fields that might display rather than to show complete output.

The fields that display depend upon the LSA type as shown in the following table.

TABLE 222 OSPF V3 detailed database information fields

Field	Description
Router LSA (Type 1) (Rtr) fields	
Capability Bits	<p>A bit that indicates the capability of the Brocade device. The bit can be set to one of the following:</p> <ul style="list-style-type: none"> • B – The device is an area border router. • E – The device is an AS boundary router. • V – The device is a virtual link endpoint. • W – The device is a wildcard multicast receiver.
Options	<p>A 24-bit field that enables IPv6 OSPF routers to support the optional capabilities. When set, the following bits indicate the following:</p> <p>V6 – The device should be included in IPv6 routing calculations.</p> <p>E – The device floods AS-external-LSAs as described in RFC 2740.</p> <p>MC – The device forwards multicast packets as described in RFC 1586.</p> <p>N – The device handles type 7 LSAs as described in RFC 1584.</p> <p>R – The originator is an active router.</p> <p>DC – The device handles demand circuits.</p>
Type	<p>The type of interface. Possible types can be the following:</p> <ul style="list-style-type: none"> • Point-to-point – A point-to-point connection to another router. • Transit – A connection to a transit network. • Virtual link – A connection to a virtual link.
Metric	The cost of using this router interface for outbound traffic.
Interface ID	The ID assigned to the router interface.
Neighbor Interface ID	The interface ID that the neighboring router has been advertising in hello packets sent on the attached link.
Neighbor Router ID	The router ID (IPv4 address) of the neighboring router that advertised the route. (By default, the Brocade router ID is the IPv4 address configured on the lowest numbered loopback interface. If the Brocade device does not have a loopback interface, the default router ID is the lowest numbered IPv4 address configured on the device.)

TABLE 222 OSPF V3 detailed database information fields (Continued)

Field	Description
Network LSA (Type 2) (Net) fields	
Options	A 24-bit field that enables IPv6 OSPF routers to support the optional capabilities. When set, the following bits indicate the following: V6 – The device should be included in IPv6 routing calculations. E – The device floods AS-external-LSAs as described in RFC 2740. MC – The device forwards multicast packets as described in RFC 1586. N – The device handles type 7 LSAs as described in RFC 1584. R – The originator is an active router. DC – The device handles demand circuits.
Attached Router	The address of the neighboring router that advertised the route.
Inter-Area Prefix LSA (Type 3) (Inap) fields	
Metric	The cost of the route.
Prefix Options	An 8-bit field describing various capabilities associated with the prefix.
Prefix	The IPv6 prefix included in the LSA.
Inter-Area Router LSA (Type 4) (Inar) fields	
Options	A 24-bit field that enables IPv6 OSPF routers to support the optional capabilities. When set, the following bits indicate the following: V6 – The device should be included in IPv6 routing calculations. E – The device floods AS-external-LSAs as described in RFC 2740. MC – The device forwards multicast packets as described in RFC 1586. N – The device handles type 7 LSAs as described in RFC 1584. R – The originator is an active router. DC – The device handles demand circuits.
Metric	The cost of the route.
Destination Router ID	The ID of the router described in the LSA.
AS External LSA (Type 5) (Extn) fields	
Bits	The bit can be set to one of the following: <ul style="list-style-type: none"> • E – If bit E is set, a Type 2 external metric. If bit E is zero, a Type 1 external metric. • F – A forwarding address is included in the LSA. • T – An external route tag is included in the LSA.
Metric	The cost of this route, which depends on bit E.
Prefix Options	An 8-bit field describing various capabilities associated with the prefix.
Referenced LS Type	If non-zero, an LSA with this LS type is associated with the LSA.
Prefix	The IPv6 prefix included in the LSA.
Link LSA (Type 8) (Link) fields	
Router Priority	The router priority of the interface attaching the originating router to the link.
Options	The set of options bits that the router would like set in the network LSA that will be originated for the link.
Link Local Address	The originating router link-local interface address on the link.
Number of Prefix	The number of IPv6 address prefixes contained in the LSA.

TABLE 222 OSPF V3 detailed database information fields (Continued)

Field	Description
Prefix Options	An 8-bit field of capabilities that serve as input to various routing calculations: <ul style="list-style-type: none"> • NU – The prefix is excluded from IPv6 unicast calculations. • LA – The prefix is an IPv6 interface address of the advertising router. • MC – The prefix is included in IPv6 multicast routing calculations.
Prefix	The IPv6 prefix included in the LSA.
Intra-Area Prefix LSAs (Type 9) (lap) fields	
Number of Prefix	The number of prefixes included in the LSA.
Referenced LS Type, Referenced LS ID	Identifies the router-LSA or network-LSA with which the IPv6 address prefixes are associated.
Referenced Advertising Router	The address of the neighboring router that advertised the route.
Prefix Options	An 8-bit field describing various capabilities associated with the prefix.
Metric	The cost of using the advertised prefix.
Prefix	The IPv6 prefix included in the LSA.
Number of Prefix	The number of prefixes included in the LSA.

Displaying OSPF V3 interface information

You can display a summary of information for all OSPF V3 interfaces or detailed information about a specified OSPF V3 interface.

To display a summary of OSPF V3 interfaces, enter the **show ipv6 ospf interface** command at any CLI level.

```
Brocade#show ipv6 ospf interface
Interface  OSPF      Status State   Area
-----
ethe 3/1   up
ethe 3/2   enabled  up      DR      0
ethe 3/4   disabled down
loopback 2 enabled  up      Loopback 0
tunnel 1   disabled down
tunnel 2   enabled  up      P2P     0
tunnel 6   up
```

Syntax: **show ipv6 ospf interface** [**ethernet** <port> | **loopback** <number> | **tunnel** <number> | **ve** <number>]

The **ethernet** | **loopback** | **tunnel** | **ve** parameter specifies the interface for which to display information. If you specify an Ethernet interface, also specify the port number associated with the interface. If you specify a loopback, tunnel, or VE interface, also specify the number associated with the interface.

This display shows the following information.

TABLE 223 Summary of OSPF V3 interface information

Field	Description
Interface	The interface type, and the port number or number of the interface.
OSPF	The state of OSPF V3 on the interface. Possible states include the following: <ul style="list-style-type: none"> • Enabled. • Disabled.
Status	The status of the link. Possible status include the following: <ul style="list-style-type: none"> • Up. • Down.
State	The state of the interface. Possible states includes the following: <ul style="list-style-type: none"> • DR – The interface is functioning as the Designated Router for OSPF V3. • BDR – The interface is functioning as the Backup Designated Router for OSPF V3. • Loopback – The interface is functioning as a loopback interface. • P2P – The interface is functioning as a point-to-point interface. • Passive – The interface is up but it does not take part in forming an adjacency. • Waiting – The interface is trying to determine the identity of the BDR for the network. • None – The interface does not take part in the OSPF interface state machine. • Down – The interface is unusable. No protocol traffic can be sent or received on such a interface. • DR other – The interface is a broadcast or NBMA network on which another router is selected to be the DR.
Area	The OSPF area to which the interface belongs.

For example, to display detailed information about Ethernet interface 2, enter the **show ipv6 ospf interface ethernet** command at any level of the CLI.

```

Brocade#show ipv6 ospf interface ethernet 3/2
ethe 3/2 is up, type BROADCAST
  IPv6 Address:
    2002:c0a8:46a::1/64
    2000:4::106/64

```

This display shows the following information.

TABLE 224 Detailed OSPF V3 interface information

Field	Description
Interface status	The status of the interface. Possible status includes the following: <ul style="list-style-type: none"> Up. Down.
Type	The type of OSPF V3 circuit running on the interface. Possible types include the following: <ul style="list-style-type: none"> BROADCAST POINT TO POINT UNKNOWN
IPv6 Address	The IPv6 address(es) assigned to the interface.
Instance ID	An identifier for an instance of OSPF V3.
Router ID	The IPv4 address of the Brocade device. By default, the Brocade router ID is the IPv4 address configured on the lowest numbered loopback interface. If the device does not have a loopback interface, the default router ID is the lowest numbered IPv4 address configured on the device.
Area ID	The IPv4 address or numerical value of the area in which the interface belongs.
Cost	The overhead required to send a packet through the interface.
State	The state of the interface. Possible states include the following: <ul style="list-style-type: none"> DR – The interface is functioning as the Designated Router for OSPF V3. BDR – The interface is functioning as the Backup Designated Router for OSPF V3. Loopback – The interface is functioning as a loopback interface. P2P – The interface is functioning as a point-to-point interface. Passive – The interface is up but it does not take part in forming an adjacency. Waiting – The interface is trying to determine the identity of the BDR for the network. None – The interface does not take part in the OSPF interface state machine. Down – The interface is unusable. No protocol traffic can be sent or received on such a interface. DR other – The interface is a broadcast or NBMA network on which another router is selected to be the DR.
Transmit delay	The amount of time, in seconds, it takes to transmit Link State Updates packets on the interface.
Priority	The priority used when selecting the DR and the BDR. If the priority is 0, the interface does not participate in the DR and BDR election.
Timer intervals	The interval, in seconds, of the hello-interval, dead-interval, and retransmit-interval timers.
DR	The router ID (IPv4 address) of the DR.
BDR	The router ID (IPv4 address) of the BDR.
Number of I/F scoped LSAs	The number of interface LSAs scoped for a specified area, AS, or link.
DR Election	The number of times the DR election occurred.
Delayed LSA Ack	The number of the times the interface sent a delayed LSA acknowledgement.
Neighbor Count	The number of neighbors to which the interface is connected.
Adjacent Neighbor Count	The number of neighbors with which the interface has formed an active adjacency.

TABLE 224 Detailed OSPF V3 interface information (Continued)

Field	Description
Neighbor	The router ID (IPv4 address) of the neighbor. This field also identifies the neighbor as a DR or BDR, if appropriate.
Interface statistics	<p>The following statistics are provided for the interface:</p> <ul style="list-style-type: none"> Unknown – The number of Unknown packets transmitted and received by the interface. Also, the total number of bytes associated with transmitted and received Unknown packets. Hello – The number of Hello packets transmitted and received by the interface. Also, the total number of bytes associated with transmitted and received Hello packets. DbDesc – The number of Database Description packets transmitted and received by the interface. Also, the total number of bytes associated with transmitted and received Database Description packets. LSReq – The number of link-state requests transmitted and received by the interface. Also, the total number of bytes associated with transmitted and received link-state requests. LSUpdate – The number of link-state updates transmitted and received by the interface. Also, the total number of bytes associated with transmitted and received link-state requests. LSAck – The number of link-state acknowledgements transmitted and received by the interface. Also, the total number of bytes associated with transmitted and received link-state acknowledgements.

Displaying OSPF V3 memory usage

To display information about OSPF V3 memory usage, enter the **show ipv6 ospf memory** command at any level of the CLI.

```

Brocade#show ipv6 ospf memory
Total Static Memory Allocated : 5829 bytes
Total Dynamic Memory Allocated : 0 bytes
Memory Type           Size      Allocated  Max-alloc  Alloc-Fails

MTYPE_OSPF6_NEXTHOP    0          0           0           0
MTYPE_OSPF6_EXTERNAL_INFO 0          0           0           0
MTYPE_THREAD           0          0           0           0

```

Syntax: show ipv6 ospf memory

This display shows the following information.

TABLE 225 OSPF V3 memory usage information

Field	Description
Total Static Memory Allocated	A summary of the amount of static memory allocated, in bytes, to OSPF V3.
Total Dynamic Memory Allocated	A summary of the amount of dynamic memory allocated, in bytes, to OSPF V3.
Memory Type	The type of memory used by OSPF V3. (This information is for use by Brocade technical support in case of a problem.)
Size	The size of a memory type.
Allocated	The amount of memory currently allocated to a memory type.
Max-alloc	The maximum amount of memory that was allocated to a memory type.
Alloc-Fails	The number of times an attempt to allocate memory to a memory type failed.

Displaying OSPF V3 neighbor information

You can display a summary of OSPF V3 neighbor information for the Brocade device or detailed information about a specified neighbor.

To display a summary of OSPF V3 neighbor information for the device, enter the **show ipv6 ospf neighbor** command at any CLI level.

```
Brocade#show ipv6 ospf neighbor
RouterID      Pri State      DR                      BDR                      Interface[State]
1.1.1.1       1 Full      223.223.223.223 1.1.1.1                ethe 3/2 [DR]
```

Syntax: **show ipv6 ospf neighbor** [**router-id** <ipv4-address>]

The **router-id** <ipv4-address> parameter displays only the neighbor entries for the specified router.

This display shows the following information.

TABLE 226 Summary of OSPF V3 neighbor information

Field	Description
Router ID	The IPv4 address of the neighbor. By default, the Brocade router ID is the IPv4 address configured on the lowest numbered loopback interface. If the device does not have a loopback interface, the default router ID is the lowest numbered IPv4 address configured on the device.
Pri	The OSPF V3 priority of the neighbor. The priority is used during election of the DR and BDR.
State	The state between the Brocade device and the neighbor. The state can be one of the following: <ul style="list-style-type: none"> • Down • Attempt • Init • 2-Way • ExStart • Exchange • Loading • Full
DR	The router ID (IPv4 address) of the DR.

TABLE 226 Summary of OSPF V3 neighbor information (Continued)

Field	Description
BDR	The router ID (IPv4 address) of the BDR.
Interface [State]	<p>The interface through which the router is connected to the neighbor. The state of the interface can be one of the following:</p> <ul style="list-style-type: none"> • DR – The interface is functioning as the Designated Router for OSPF V3. • BDR – The interface is functioning as the Backup Designated Router for OSPF V3. • Loopback – The interface is functioning as a loopback interface. • P2P – The interface is functioning as a point-to-point interface. • Passive – The interface is up but it does not take part in forming an adjacency. • Waiting – The interface is trying to determine the identity of the BDR for the network. • None – The interface does not take part in the OSPF interface state machine. • Down – The interface is unusable. No protocol traffic can be sent or received on such a interface. • DR other – The interface is a broadcast or NBMA network on which another router is selected to be the DR.

For example, to display detailed information about a neighbor with the router ID of 1.1.1.1, enter the **show ipv6 ospf neighbor router-id** command at any CLI level.

```

Brocade#show ipv6 ospf neighbor router-id 3.3.3.3
RouterID      Pri State      DR          BDR          Interface[State]

```

This display shows the following information.

TABLE 227 Detailed OSPF V3 neighbor information

Field	Description
Router ID	For information about this field, refer to Table 226 on page 1325.
Pri	For information about this field, refer to Table 226 on page 1325.
State	For information about this field, refer to Table 226 on page 1325.
DR	For information about this field, refer to Table 226 on page 1325.
BDR	For information about this field, refer to Table 226 on page 1325.
Interface [State]	For information about this field, refer to Table 226 on page 1325.

TABLE 227 Detailed OSPF V3 neighbor information (Continued)

Field	Description
DbDesc bit...	The Database Description packet, which includes 3 bits of information: <ul style="list-style-type: none"> • The first bit can be “i” or “-”. “i” indicates the inet bit is set. “-” indicates the inet bit is not set. • The second bit can be “m” or “-”. “m” indicates the more bit is set. “-” indicates the more bit is not set. • The third bit can be “m” or “s”. An “m” indicates the master. An “s” indicates standby.
Index	The ID of the LSA from which the neighbor learned of the router.
DR Decision	The router ID (IPv4 address) of the neighbor elected DR and BDR.
Last Received Db Desc	The content of the last database description received from the specified neighbor.
Number of LSAs in Db Desc retransmitting	The number of LSAs that need to be retransmitted to the specified neighbor.
Number of LSAs in Summary List	The number of LSAs in the neighbor summary list.
Number of LSAs in Request List	The number of LSAs in the neighbor request list.
Number of LSAs in Retransmit List	The number of LSAs in the neighbor retransmit list.
Seqnum Mismatch	The number of times sequence number mismatches occurred.
BadLSReq	The number of times the neighbor received a bad link-state request from the Brocade device.
One way received	The number of times a hello packet, which does not mention the router, is received from the neighbor. This omission in the hello packet indicates that the communication with the neighbor is not bidirectional.
Inactivity Timer	The number of times that the neighbor inactivity timer expired.
Db Desc Retransmission	The number of times sequence number mismatches occurred.
LSReqRetrans	The number of times the neighbor retransmitted link-state requests to the Brocade device.
LSUpdateRetrans	The number of times the neighbor retransmitted link-state updates to the Brocade device.
LSA Received	The number of times the neighbor received LSAs from the Brocade device.
LS Update Received	The number of times the neighbor received link-state updates from the Brocade device.

Displaying routes redistributed into OSPF V3

You can display all IPv6 routes or a specified IPv6 route that the Brocade device has redistributed into OSPF V3.

To display all IPv6 routes that the device has redistributed into OSPF V3, enter the **show ipv6 ospf redistribute route** command at any level of the CLI.

```
Brocade#show ipv6 ospf redistribute route
Id      Prefix
snIpAsPathAccessListStringRegExpression
1       2002::/16
2       2002:1234::/32
Protocol Metric Type Metric
Static   Type-2      1
Static   Type-2      1
```

Syntax: `show ipv6 ospf redistribute route [<ipv6-prefix>]`

The `<ipv6-prefix>` parameter specifies an IPv6 network prefix. (You do not need to specify the length of the prefix.)

For example, to display redistribution information for the prefix 2002::, enter the **show ipv6 ospf redistribute route** command at any level of the CLI.

```
Brocade#show ipv6 ospf redistribute route 2002::
Id      Prefix
1       2002::/16
Protocol Metric Type Metric
Static   Type-2      1
```

These displays show the following information.

TABLE 228 OSPF V3 redistribution information

Field	Description
ID	An ID for the redistributed route.
Prefix	The IPv6 routes redistributed into OSPF V3.
Protocol	The protocol from which the route is redistributed into OSPF V3. Redistributed protocols can be the following: <ul style="list-style-type: none"> • RIP – RIPv6. • Static – IPv6 static route table. • Connected – A directly connected network.
Metric Type	The metric type used for routes redistributed into OSPF V3. The metric type can be the following: <ul style="list-style-type: none"> • Type-1 – Specifies a small metric (2 bytes). • Type-2 – Specifies a big metric (3 bytes).
Metric	The value of the default redistribution metric, which is the OSPF cost of redistributing the route into OSPF V3.

Displaying OSPF V3 route information

You can display the entire OSPF V3 route table for the Brocade device or only the route entries for a specified destination.

To display the entire OSPF V3 route table for the device, enter the **show ipv6 ospf routes** command at any level of the CLI.

```

Brocade#show ipv6 ospf routes
Current Route count: 4
  Intra: 4 Inter: 0 External: 0 (Type1 0/Type2 0)
  Equal-cost multi-path: 0
  Destination          Options   Area          Cost Type2 Cost
  Next Hop Router      Outgoing Interface
*IA 2000:4::/64        V6E---R-- 0.0.0.0        1 0
  ::                   ethe 3/2
*IA 2002:c0a8:46a::/64 V6E---R-- 0.0.0.0        1 0
  ::                   ethe 3/2
*IA 2999::1/128        ----- 0.0.0.0        0 0
  ::                   loopback 2
*IA 2999::2/128        V6E---R-- 0.0.0.0        1 0
  fe80::2e0:52ff:fe91:bb37 ethe 3/2

```

Syntax: `show ipv6 ospf routes [<ipv6-prefix>]`

The `<ipv6-prefix>` parameter specifies a destination IPv6 prefix. (You do not need to specify the length of the prefix.) If you use this parameter, only the route entries for this destination are shown.

For example, to display route information for the destination prefix 2000:4::, enter the **show ipv6 ospf routes** command at any level of the CLI.

```

Brocade#show ipv6 ospf routes 2000:4::
Destination          Options   Area          Cost Type2 Cost
Next Hop Router      Outgoing Interface
*IA 2000:4::/64      V6E---R-- 0.0.0.0        1 0
  ::                 ethe 3/2

```

These displays show the following information.

TABLE 229 OSPF V3 route information

Field	Description
Current Route Count (Displays with the entire OSPF V3 route table only)	The number of route entries currently in the OSPF V3 route table.
Intra/Inter/External (Type1/Type2) (Displays with the entire OSPF V3 route table only)	<p>The breakdown of the current route entries into the following route types:</p> <ul style="list-style-type: none"> • Inter – The number of routes that pass into another area. • Intra – The number of routes that are within the local area. • External1 – The number of type 1 external routes. • External2 – The number of type 2 external routes.
Equal-cost multi-path (Displays with the entire OSPF V3 route table only)	The number of equal-cost routes to the same destination in the OSPF V3 route table. If load sharing is enabled, the router equally distributes traffic among the routes.
Destination	The IPv6 prefixes of destination networks to which the Brocade device can forward IPv6 packets. “*IA” indicates the next router is an intra-area router.

TABLE 229 OSPF V3 route information (Continued)

Field	Description
Options	A 24-bit field that enables IPv6 OSPF routers to support the optional capabilities. When set, the following bits indicate the following: V6 – The device should be included in IPv6 routing calculations. E – The device floods AS-external-LSAs as described in RFC 2740. MC – The device forwards multicast packets as described in RFC 1586. N – The device handles type 7 LSAs as described in RFC 1584. R – The originator is an active router. DC – The device handles demand circuits.
Area	The area whose link state information has led to the routing table entry's collection of paths.
Cost	The type 1 cost of this route.
Type2 Cost	The type 2 cost of this route.
Next-Hop Router	The IPv6 address of the next router a packet must traverse to reach a destination.
Outgoing Interface	The router interface through which a packet must traverse to reach the next-hop router.

Displaying OSPF V3 SPF information

You can display the following OSPF V3 SPF information:

- SPF node information for a specified area.
- SPF table for a specified area.
- SPF tree for a specified area.

For example, to display information about SPF nodes in area 0, enter the **show ipv6 ospf spf node area** command at any level of the CLI.

```
Brocade#show ipv6 ospf spf node area 0
SPF node for Area 0
SPF node 223.223.223.223, cost: 0, hops: 0
  nexthops to node:
  parent nodes:
  child nodes: 223.223.223.223:88

SPF node 223.223.223.223:88, cost: 1, hops: 1
  nexthops to node:    :: ethe 3/2
  parent nodes: 223.223.223.223
  child nodes: 1.1.1.1:0

SPF node 1.1.1.1:0, cost: 1, hops: 2
  nexthops to node:    fe80::2e0:52ff:fe91:bb37 ethe 3/2
  parent nodes: 223.223.223.223:88
  child nodes:
```

Syntax: `show ipv6 ospf spf node area [<area-id>]`

The **node** keyword displays SPF node information.

The **area** *<area-id>* parameter specifies a particular area. You can specify the *<area-id>* in the following formats:

- As an IPv4 address; for example, 192.168.1.1.
- As a numerical value from 0 – 2,147,483,647.

This display shows the following information.

TABLE 230 OSPF V3 SPF node information

Field	Description
SPF node	Each SPF node is identified by its router ID (IPv4 address). If the node is a child node, it is additionally identified by an interface on which the node can be reached appended to the router ID in the format <i><router-id>:<interface-id></i> .
Cost	The cost of traversing the SPF node to reach the destination.
Hops	The number of hops needed to reach the parent SPF node.
Next Hops to Node	The IPv6 address of the next hop-router or the router interface, or both, through which to access the next-hop router.
Parent Nodes	The SPF node parent nodes. A parent node is an SPF node at the highest level of the SPF tree, which is identified by its router ID.
Child Nodes	The SPF node child nodes. A child node is an SPF node at a lower level of the SPF tree, which is identified by its router ID and interface on which the node can be reached.

For example, to display the SPF table for area 0, enter the **show ipv6 ospf spf table area** command at any level of the CLI.

```
Brocade#show ipv6 ospf spf table area 0
  SPF table for Area 0
  Destination          Bits Options  Cost  Nexthop                               Interface
R 1.1.1.1              ---- V6E---R-    1  fe80::2e0:52ff:fe91:bb37             ethe 3/2
N 223.223.223.223[88]  ---- V6E---R-    1  ::                                     ethe 3/2
```

Syntax: `show ipv6 ospf spf table area <area-id>`

The **table** parameter displays the SPF table.

The **area** *<area-id>* parameter specifies a particular area. You can specify the *<area-id>* in the following formats:

- As an IPv4 address, for example, 192.168.1.1.
- As a numerical value from 0 – 2,147,483,647.

This display shows the following information.

TABLE 231 OSPF V3 SPF table

Field	Description
Destination	The destination of a route, which is identified by the following: <ul style="list-style-type: none"> • “R”, which indicates the destination is a router. “N”, which indicates the destination is a network. • An SPF node router ID (IPv4 address). If the node is a child node, it is additionally identified by an interface on which the node can be reached appended to the router ID in the format <i><router-id>:<interface-id></i>.
Bits	A bit that indicates the capability of the Brocade device. The bit can be set to one of the following: <ul style="list-style-type: none"> • B – The device is an area border router. • E – The device is an AS boundary router. • V – The device is a virtual link endpoint. • W – The device is a wildcard multicast receiver.
Options	A 24-bit field that enables IPv6 OSPF routers to support the optional capabilities. When set, the following bits indicate the following: <ul style="list-style-type: none"> V6 – The router should be included in IPv6 routing calculations. E – The router floods AS-external-LSAs as described in RFC 2740. MC – The router forwards multicast packets as described in RFC 1586. N – The router handles type 7 LSAs as described in RFC 1584. R – The originator is an active router. DC – The router handles demand circuits.
Cost	The cost of traversing the SPF node to reach the destination.
Next hop	The IPv6 address of the next hop-router.
Interface	The router interface through which to access the next-hop router.

For example, to display the SPF tree for area 0, enter the **show ipv6 ospf spf tree area** command at any level of the CLI.

```
Brocade#show ipv6 ospf spf tree area 0
  SPF tree for Area 0
+- 223.223.223.223 cost 0
   +- 223.223.223.223:88 cost 1
      +- 1.1.1.1:0 cost 1
```

Syntax: **show ipv6 ospf spf tree area** *<area-id>*

The **tree** keyword displays the SPF table.

The **area** *<area-id>* parameter specifies a particular area. You can specify the *<area-id>* in the following formats:

- As an IPv4 address; for example, 192.168.1.1.
- As a numerical value from 0 – 2,147,483,647.

In this sample output, consider the SPF node with the router ID 223.223.223.223 to be the top (root) of the tree and the local router. Consider all other layers of the tree (223.223.223.223:88 and 1.1.1.1:0) to be destinations in the network. Therefore, traffic destined from router 223.223.223.223 to router 1.1.1.1:0 must first traverse router 223.223.223.223:88.

Displaying IPv6 OSPF virtual link information

To display OSPF V3 virtual link information for the Brocade device, enter the **show ipv6 ospf virtual-link** command at any level of the CLI.

```
Brocade#show ipv6 ospf virtual-link
Index Transit Area ID Router ID Interface Address State
1      1              1.1.1.1      3003::2      P2P
```

Syntax: **show ipv6 ospf virtual-link**

This display shows the following information.

TABLE 232 OSPF V3 virtual link information

Field	Description
Index	An index number associated with the virtual link.
Transit Area ID	The ID of the shared area of two ABRs that serves as a connection point between the two routers.
Router ID	IPv4 address of the router at the other end of the virtual link (virtual neighbor).
Interface Address	The local address used to communicate with the virtual neighbor.
State	The state of the virtual link. Possible states include the following: <ul style="list-style-type: none"> P2P – The link is functioning as a point-to-point interface. DOWN – The link is down.

Displaying OSPF V3 virtual neighbor information

To display OSPF V3 virtual neighbor information for the Brocade device, enter the **show ipv6 ospf virtual-neighbor** command at any level of the CLI.

```
Brocade#show ipv6 ospf virtual-neighbor
Index Router ID Address State Interface
1      1.1.1.1    3002::1 Full ethe 2/3
```

Syntax: **show ipv6 ospf virtual-neighbor**

This display shows the following information.

TABLE 233 OSPF V3 virtual neighbor information

Field	Description
Index	An index number associated with the virtual neighbor.
Router ID	IPv4 address of the virtual neighbor.
Address	The IPv6 address to be used for communication with the virtual neighbor.

TABLE 233 OSPF V3 virtual neighbor information (Continued)

Field	Description
State	The state between the Brocade device and the virtual neighbor. The state can be one of the following: <ul style="list-style-type: none"> • Down • Attempt • Init • 2-Way • ExStart • Exchange • Loading • Full
Interface	The IPv6 address of the virtual neighbor.

IPsec examples

This section contains examples of IPsec configuration and the output from the IPsec-specific **show** commands. In addition, IPsec-related information appears in general **show** command output for interfaces and areas.

The **show** commands that are specific to IPsec are:

- **show ipsec sa**
- **show ipsec policy**
- **show ipsec statistics**

The other **show** commands with IPsec-related information are:

- **show ipv6 ospf area**
- **show ipv6 ospf interface**

Showing IPsec security association information

The **show ipsec sa** command displays the IPsec security association databases, as follows.

```
Brocade#show ipsec sa
IPSEC Security Association Database(Entries:8)
SPDID(if)   Dir  Encap  SPI      Destination      AuthAlg  EncryptAlg
ALL         in   ESP    512      35:1:1::1        sha1     Null
eth1/1/1    out  ESP    302      ::               sha1     Null
eth1/1/1    in   ESP    302      FE80::           sha1     Null
eth1/1/1    out  ESP    512      10:1:1::2        sha1     Null
ALL         in   ESP    512      35:1:1::1        sha1     Null
eth1/1/2    out  ESP    302      ::               sha1     Null
eth1/1/2    in   ESP    302      FE80::           sha1     Null
eth1/1/2    out  ESP    512      10:1:1::2        sha1     Null
```

Syntax: **show ipsec sa**

Showing IPsec policy

The **show ipsec policy** command displays the database for the IPsec security policies. The fields for this **show** command output appear in the screen output example that follows. However, you should understand the layout and column headings for the display before trying to interpret the information in the example screen.

Each policy entry consists of two categories of information:

- The policy information
- The SA used by the policy

The policy information line in the screen begins with the heading Ptype and also has the headings Dir, Proto, Source (Prefix:TCP/UDP Port), and Destination (Prefix:TCP/UDPPort). The SA line contains the SPDID, direction, encapsulation (always ESP in the current release), the user-specified SPI, For readability, the policy information is described in [Table 234](#), and SA-specific information is in [Table 235](#).

```
Brocade#show ipsec policy
          IPSEC Security Policy Database(Entries:8)
PType  Dir Proto Source(Prefix:TCP/UDP Port)  Destination(Prefix:TCP/UDPPort)
SA: SPDID(if) Dir Encap SPI      Destination
use   in  OSPF FE80::/10:any          ::/0:any
SA: eth1/1/2 in  ESP   302          FE80::
use   out OSPF FE80::/10:any          ::/0:any
SA: eth1/1/2 out ESP   302          ::
use   in  OSPF FE80::/10:any          ::/0:any
SA: eth1/1/1 in  ESP   302          FE80::
use   out OSPF FE80::/10:any          ::/0:any
SA: eth1/1/1 out ESP   302          ::
use   in  OSPF 35:1:1::1/128:any      10:1:1::2/128:any
SA: ethALL in  ESP   512          10:1:1::2
use   out OSPF 10:1:1::2/128:any      35:1:1::1/128:any
SA: eth1/1/1 out ESP   512          35:1:1::1
use   in  OSPF 35:1:1::1/128:any      10:1:1::2/128:any
SA: ethALL in  ESP   512          10:1:1::2
use   out OSPF 10:1:1::2/128:any      35:1:1::1/128:any
```

Syntax: **show ipsec policy**

This command takes no parameters.

TABLE 234 IPsec policy information

Field	Description
PType	This field contains the policy type. Of the existing policy types, only the “use” policy type is supported, so each entry can have only “use.”
Dir	The direction of traffic flow to which the IPsec policy is applied. Each direction has its own entry.
Proto	The only possible routing protocol for the security policy in the current release is OSPFv3.

TABLE 234 IPsec policy information (Continued)

Field	Description
Source	The source address consists of the IPv6 prefix and the TCP or UDP port identifier.
Destination	<p>The destination address consists of the IPv6 prefix. Certain logical elements have a bearing on the meaning of the destination address and its format, as follows:</p> <p>For IPsec on an interface or area, the destination address is shown as a prefix of 0xFE80 (link local). The solitary "::" (no prefix) indicates a "do not-care" situation because the connection is multicast. In this case, the security policy is enforced without regard for the destination address.</p> <p>For a virtual link (SPDID = 0), the address is required.</p>

TABLE 235 SA used by the policy

Field	Description
SA	This heading points at the SA-related headings for information used by the security policy. Thereafter, on each line of this part of the IPsec entry (which alternates with lines of policy information Table 234), "SA:" points at the fields under those SA-related headings. The remainder of this table describes each of the SA-related items.
SPDID	The Security policy database identifier (SPDID) consists of interface type and Interface ID.
Dir	The Dir field is either 'in' for inbound or "out" for outbound.
Encap	The type of encapsulation in the current release is ESP.
SPI	Security parameter index.
Destination	<p>The IPv6 address of the destination endpoint. From the standpoint of the near interface and the area, the destination is not relevant and therefore appears as ::/0:any.</p> <p>For a virtual link, both the inbound and outbound destination addresses are relevant.</p>

Showing IPsec statistics

The **show ipsec statistics** command displays the error and other counters for IPSec, as this example shows.

```

Brocade#show ipsec statistics
                               IPsecrity Statistics
secEspCurrentInboundSAs 1      ipsecEspTotalInboundSAs: 2
secEspCurrentOutboundSA 1      ipsecEspTotalOutboundSAs: 2
                               IPsecrity Packet Statistics
secEspTotalInPkts:          19      ipsecEspTotalInPktsDrop: 0
secEspTotalOutPkts:         83
                               IPsecrity Error Statistics
secAuthenticationErrors 0
secReplayErrors:          0          ipsecPolicyErrors:          13
secOtherReceiveErrors:    0          ipsecSendErrors:          0
secAuthenticationErrors 0
secReplayErrors:          0          ipsecPolicyErrors:          13
secOtherReceiveErrors:    0          ipsecSendErrors:          0
secUnknownSpiErrors:      0

```

Syntax: `show ipsec statistics`

This command takes no parameters.

Displaying IPsec configuration for an area

The `show ipv6 ospf area [<area-id>]` command includes information about IPsec for one area or all areas. In the example that follows, the IPsec information is in bold. IPsec is enabled in the first area (area 0) in this example but not in area 3. Note that in area 3, the IPsec key was specified as not encrypted.

```
Brocade(config-ospf6-router)#show ipv6 ospf area
Authentication: Configured
KeyRolloverTime(sec): Configured: 25 Current: 20
KeyRolloverState: Active,Phase1
Current: None
New: SPI:400, ESP, SHA1
Key:$Z|83OmYW{QZ|83OmYW{QZ|83OmYW{QZ|83OmYW{Q
Interface attached to this area: eth 1/1/1
Number of Area scoped LSAs is 6
Sum of Area LSAs Checksum is 0004f7de
Statistics of Area 0:
    SPF algorithm executed 6 times
    SPF last updated: 482 sec ago
    Current SPF node count: 1
        Router: 1 Network: 0
        Maximum of Hop count to nodes: 0
Area 3:
Authentication: Not Configured
Interface attached to this area:
Number of Area scoped LSAs is 3
```

Syntax: `show ipv6 ospf area [<area-id>]`

The `<area-id>` parameter restricts the display to the specified OSPF area. You can specify the `<area-id>` parameter in the following formats:

- An IPv4 address, for example, 192.168.1.1
- A numerical value in the range 0 – 2,147,483,647

TABLE 236 Area configuration of IPsec

Field	Description
Authentication	This field shows whether or not authentication is configured. If this field says "Not Configured," the IPsec-related fields (bold in example screen output) are not displayed at all.
KeyRolloverTime	The number of seconds between each initiation of a key rollover. This field shows the configured and current times.
KeyRolloverState	Can be: Not active: key rollover is not active> Active phase 1: rollover is in its first interval. Active phase 2: rollover is in its second interval.
Current	Shows current SPI, authentication algorithm (currently ESP only), encryption algorithm (currently SHA1 only), and the current key.

TABLE 236 Area configuration of IPsec (Continued)

Field	Description
New	Shows new SPI (if changed), authentication algorithm (currently ESP only), encryption algorithm (currently SHA1 only), and the new key.
Old	Shows old SPI (if changed), authentication algorithm (currently ESP only), encryption algorithm (currently SHA1 only), and the old key.

Displaying IPsec for an interface

To see IPsec configuration for a particular interface or all interfaces, use the **show ipv6 ospf interface** command as in the following example (IPsec information in bold).

```

Brocade#show ipv6 ospf interface
eth 1/1/3 is down, type BROADCAST
  Interface is disabled

eth 1/1/8 is up, type BROADCAST
  IPv6 Address:
    2100:18:18:18:18::1/64
    2100:18:18:18:18::/64
  Instance ID 255, Router ID 1.1.1.1
  Area ID 1, Cost 1
  State BDR, Transmit Delay 1 sec, Priority 1
  Timer intervals :
    Hello 10, Hello Jitter 10  Dead 40, Retransmit 5
Authentication: Enabled

    LSAck     85       109     4840     4924
OSPF messages dropped,no authentication: 0

Syntax: show ipv6 ospf interface [ethernet <slot/port> | pos <slot/port> | loopback <number> |
      tunnel <number> | ve <number>]

```

TABLE 237 Area configuration of IPsec

Field	Description
Authentication	This field shows whether or not authentication is configured. If this field says "Not Configured," the IPsec-related fields (bold in example screen output) are not displayed at all.
KeyRolloverTime	The number of seconds between each initiation of a key rollover. This field shows the configured and current times.
KeyRolloverState	Can be: Not active: key rollover is not active> Active phase 1: rollover is in its first interval. Active phase 2: rollover is in its second interval.
Current	Shows current SPI, authentication algorithm (currently ESP only), encryption algorithm (currently SHA1 only), and the current key.
New (Inbound or Outbound)	Shows new SPI (if changed), authentication algorithm (currently ESP only), encryption algorithm (currently SHA1 only), and the new key.
Old (Inbound or Outbound)	Shows old SPI (if changed), authentication algorithm (currently ESP only), encryption algorithm (currently SHA1 only), and the old key.
OSPF messages dropped	Shows the number of packets dropped because the packets failed authentication (for any reason).

Displaying IPsec for a virtual link

To display IPsec for a virtual link, run the **show ipv6 ospf virtual-link brief** or **show ipv6 ospf virtual-link** command, as the following examples illustrate.

```

Brocade#show ipv6 ospf virtual-link brief
Index Transit Area ID Router ID Interface Address State
1 1 14.14.14.14 3000:1:1:1::1 P2P

Brocade#show ipv6 ospf virtual-link
Transit Area ID Router ID Interface Address State
1 14.14.14.14 3000:1:1:1::1 P2P
Timer intervals(sec) :
Hello 10, Hello Jitter 10, Dead 40, Retransmit 5, TransmitDelay 1
DelayedLSAck: 5 times
Authentication: Configured
KeyRolloverTime(sec): Configured: 10 Current: 0
KeyRolloverState: NotActive
Outbound: SPI:100004, ESP, SHA1
Key:1234567890123456789012345678901234567890
Inbound: SPI:100004, ESP, SHA1
Key:1234567890123456789012345678901234567890
Statistics:
Type tx rx tx-byte rx-byte
Unknown 0 0 0 0
Hello 65 65 2600 2596
DbDesc 4 4 2752 2992
LSReq 1 1 232 64
LSUpdate 11 5 1040 1112
LSAck 5 8 560 448
OSPF messages dropped,no authentication: 0
Neighbor: State: Full Address: 2004:44:44:44::4 Interface: eth 2/2

```

Syntax: `show ipv6 ospf virtual-link [brief]`

The optional [brief] keyword limits the display to the Transit, Area ID, Router ID, Interface Address, and State fields for each link.

Changing a key

In this example, the key is changed as illustrated in the two command lines that follow. Note that the SPI value is changed from 300 to 310 to comply with the requirement that you change the SPI when you change the key.

Initial configuration command.

```
Brocade(config-if-e10000-1/1/3)#ipv6 ospf auth ipsec spi 300 esp sha1  
no-encrypt 12345678900987655431234567890aabbccdddef
```

Command line for changing the key.

```
Brocade(config-if-e10000-1/1/3)#ipv6 ospf auth ipsec spi 310 esp sha1  
no-encrypt 989898989009876554321234567890aabbccdddef
```

BGP (IPv4)

[Table 238](#) lists individual Brocade switches and the Border Gateway Protocol (BGP4) features they support. BGP4 features are supported on FastIron X Series and Brocade FCX Series-ADV devices running the full Layer 3 software image.

NOTE

If the Brocade FCX Series device does not have a BGP license, you cannot configure BGP with the "router bgp" command at all. For details, see the chapter [“Software-based Licensing”](#) on page 199.

TABLE 238 Supported BGP4 features

Feature	FESX FSX 800 FSX 1600	FWS	FCX (-ADV models only)	ICX 6610	ICX 6450
BGP4	Yes	No	Yes	Yes	No
BGP Software License	No	No	Yes	Yes	No
BGP4 graceful restart	Yes (FSX 800 and FSX 1600 only)	No	Yes (FCX stack only)	Yes (ICX 6610 stack only)	No
BGP4 peer group	Yes	No	Yes	Yes	No
Route redistribution	Yes	No	Yes	Yes	No
Route aggregation	Yes	No	Yes	Yes	No
BGP null0 routing	Yes	No	Yes	Yes	No
Route reflection	Yes	No	Yes	Yes	No
BGP filters	Yes	No	Yes	Yes	No
Cooperative BGP4 route filtering	Yes	No	Yes	Yes	No
Route flap dampening	Yes	No	Yes	Yes	No
Multipath load sharing	Yes	No	Yes	Yes	No
Traps for BGP4	Yes	No	Yes	Yes	No

This chapter provides details on how to configure Border Gateway Protocol version 4 (BGP4) on Brocade products using the CLI.

BGP4 is described in RFC 1771. The Brocade implementation fully complies with RFC 1771. The Brocade BGP4 implementation also supports the following RFCs:

- RFC 1745 (OSPF Interactions)
- RFC 1997 (BGP Communities Attributes)
- RFC 2385 (TCP MD5 Signature Option)
- RFC 2439 (Route Flap Dampening)
- RFC 2796 (Route Reflection)

- RFC 2842 (Capability Advertisement)
- RFC 3065 (BGP4 Confederations)

To display BGP4 configuration information and statistics, refer to [“Displaying BGP4 information”](#) on page 1421.

NOTE

Your Layer 3 switch management module must have 32 MB or higher to run BGP4.

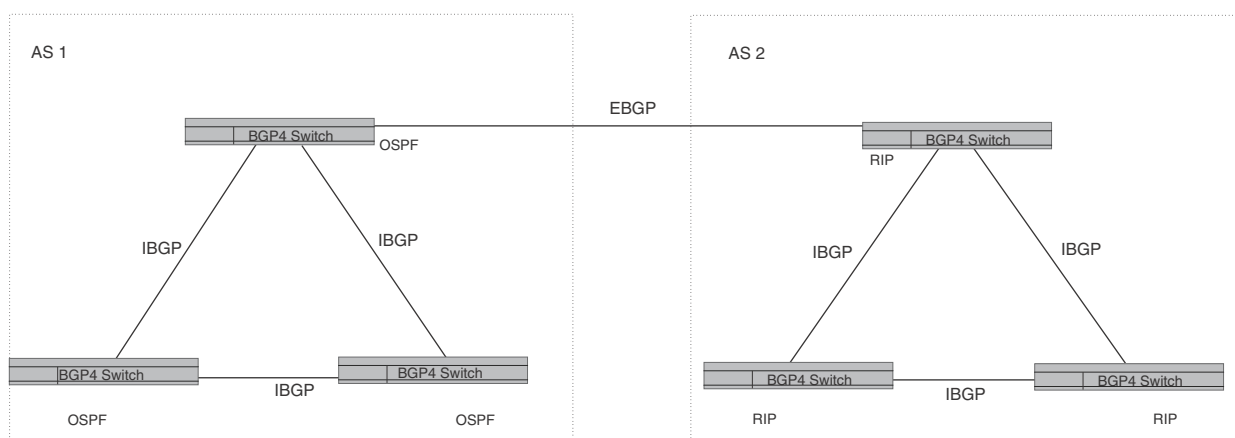

BGP4 overview

Border Gateway Protocol 4 (BGP4) is the standard Exterior Gateway Protocol (EGP) used on the Internet to route traffic between Autonomous Systems (AS) and to maintain loop-free routing. An autonomous system is a collection of networks that share the same routing and administration characteristics. For example, a corporate intranet consisting of several networks under common administrative control might be considered an AS. The networks in an AS can but do not need to run the same routing protocol to be in the same AS, nor do they need to be geographically close.

Routers within an AS can use different Interior Gateway Protocols (IGPs) such as RIP and OSPF to communicate with one another. However, for routers in different autonomous systems to communicate, they need to use an EGP. BGP4 is the standard EGP used by Internet routers and therefore is the EGP implemented on Brocade Layer 3 switches.

[Figure 166](#) on page 1342 shows a simple example of two BGP4 autonomous systems. Each AS contains three BGP4 switches. All of the BGP4 switches within an AS communicate using IBGP. BGP4 switches communicate with other autonomous systems using EBGP. Notice that each of the switches also is running an Interior Gateway Protocol (IGP). The switches in AS1 are running OSPF and the switches in AS2 are running RIP. Brocade Layer 3 switches can be configured to redistribute routes among BGP4, RIP, and OSPF. They also can redistribute static routes.

FIGURE 166 Example BGP4 autonomous systems

Relationship between the BGP4 route table and the IP route table

The Brocade Layer 3 switch BGP4 route table can have multiple routes to the same destination, which are learned from different BGP4 neighbors. A BGP4 neighbor is another switch that also is running BGP4. BGP4 neighbors communicate using Transmission Control Protocol (TCP) port 179 for BGP communication. When you configure the Brocade Layer 3 switch for BGP4, one of the configuration tasks you perform is to identify the Layer 3 switch BGP4 neighbors.

Although a Layer 3 Switch BGP4 route table can have multiple routes to the same destination, the BGP4 protocol evaluates the routes and chooses only one of the routes to send to the IP route table. The route that BGP4 chooses and sends to the IP route table is the preferred route and will be used by the Brocade Layer 3 switch. If the preferred route goes down, BGP4 updates the route information in the IP route table with a new BGP4 preferred route.

NOTE

If IP load sharing is enabled and you enable multiple equal-cost paths for BGP4, BGP4 can select more than one equal-cost path to a destination.

A BGP4 route consists of the following information:

- Network number (prefix) – A value comprised of the network mask bits and an IP address (*<IP address>/ <mask bits>*); for example, 192.215.129.0/18 indicates a network mask of 18 bits applied to the IP address 192.215.129.0. When a BGP4 Layer 3 switch advertises a route to one of its neighbors, the route is expressed in this format.
 - AS-path – A list of the other autonomous systems through which a route passes. BGP4 routers can use the AS-path to detect and eliminate routing loops. For example, if a route received by a BGP4 router contains the AS that the router is in, the router does not add the route to its own BGP4 table. (The BGP4 RFCs refer to the AS-path as “AS_PATH”.)
 - Additional path attributes – A list of additional parameters that describe the route. The route origin and next hop are examples of these additional path attributes.
-

NOTE

The Layer 3 switch re-advertises a learned best BGP4 route to the Layer 3 switch neighbors even when the software does not select that route for installation in the IP route table. The best BGP4 route is the route that the software selects based on comparison of the BGP4 route path attributes.

After a Brocade Layer 3 switch successfully negotiates a BGP4 session with a neighbor (a BGP4 peer), the Brocade Layer 3 switch exchanges complete BGP4 route tables with the neighbor. After this initial exchange, the Brocade Layer 3 switch and all other RFC 1771-compliant BGP4 routers send UPDATE messages to inform neighbors of new, changed, or no longer feasible routes. BGP4 routers do not send regular updates. However, if configured to do so, a BGP4 router does regularly send KEEPALIVE messages to its peers to maintain BGP4 sessions with them if the router does not have any route information to send in an UPDATE message. Refer to [“BGP4 message types”](#) on page 1345 for information about BGP4 messages.

How BGP4 selects a path for a route

When multiple paths for the same route are known to a BGP4 router, the router uses the following algorithm to weigh the paths and determine the optimal path for the route. The optimal path depends on various parameters, which can be modified. (Refer to [“Optional BGP4 configuration tasks”](#) on page 1365.)

1. Is the next hop accessible through an Interior Gateway Protocol (IGP) route? If not, ignore the route.

NOTE

The device does not use the default route to resolve BGP4 next hop. Also refer to [“Enabling next-hop recursion”](#) on page 1371.

2. Use the path with the largest weight.
3. If the weights are the same, prefer the route with the largest local preference.
4. If the routes have the same local preference, prefer the route that was originated locally (by this BGP4 Layer 3 switch).
5. If the local preferences are the same, prefer the route with the shortest AS-path. An AS-SET counts as 1. A confederation path length, if present, is not counted as part of the path length.
6. If the AS-path lengths are the same, prefer the route with the lowest origin type. From low to high, route origin types are valued as follows:
 - IGP is lowest
 - EGP is higher than IGP but lower than INCOMPLETE
 - INCOMPLETE is highest
7. If the routes have the same origin type, prefer the route with the lowest MED. For a definition of MED, refer to [“Configuring the Layer 3 switch to always compare Multi-Exit Discriminators \(MEDs\)”](#) on page 1377.

BGP4 compares the MEDs of two otherwise equivalent paths if and only if the routes were learned from the same neighboring AS. This behavior is called deterministic MED.

Deterministic MED is always enabled and cannot be disabled. In addition, you can enable the Layer 3 switch to always compare the MEDs, regardless of the AS information in the paths. To enable this comparison, enter the **always-compare-med** command at the BGP4 configuration level of the CLI. This option is disabled by default.

NOTE

By default, value 0 (most favorable) is used in MED comparison when the MED attribute is not present. The default MED comparison results in the Layer 3 switch favoring the route paths that are missing their MEDs. You can use the **med-missing-as-worst** command to make the Layer 3 switch regard a BGP route with a missing MED attribute as the least favorable route, when comparing the MEDs of the routes.

NOTE

MED comparison is not performed for internal routes originated within the local AS or confederation.

8. Prefer routes in the following order:
 - Routes received through EBGp from a BGP4 neighbor outside of the confederation
 - Routes received through EBGp from a BGP4 router within the confederation
 - Routes received through IBGP
9. If all the comparisons above are equal, prefer the route with the lowest IGP metric to the BGP4 next hop. This is the closest internal path inside the AS to reach the destination.
10. If the internal paths also are the same and BGP4 load sharing is enabled, load share among the paths. Otherwise, prefer the route that comes from the BGP4 router with the lowest router ID.

NOTE

Brocade Layer 3 switches support BGP4 load sharing among multiple equal-cost paths. BGP4 load sharing enables the Layer 3 switch to balance the traffic across the multiple paths instead of choosing just one path based on router ID. For EBGp routes, load sharing applies only when the paths are from neighbors within the same remote AS. EBGp paths from neighbors in different autonomous systems are not compared.

BGP4 message types

BGP4 routers communicate with their neighbors (other BGP4 routers) using the following types of messages:

- OPEN
- UPDATE
- KEEPALIVE
- NOTIFICATION

OPEN messages exchanged with BGP4 routers

After a BGP4 router establishes a TCP connection with a neighboring BGP4 router, the routers exchange OPEN messages. An OPEN message indicates the following:

- **BGP version** – Indicates the version of the protocol that is in use on the router. BGP version 4 supports Classless Interdomain Routing (CIDR) and is the version most widely used in the Internet. Version 4 also is the only version supported on Brocade Layer 3 switches.
- **AS number** – A two-byte number that identifies the AS to which the BGP4 router belongs.
- **Hold Time** – The number of seconds a BGP4 router will wait for an UPDATE or KEEPALIVE message (described below) from a BGP4 neighbor before assuming that the neighbor is dead. BGP4 routers exchange UPDATE and KEEPALIVE messages to update route information and maintain communication. If BGP4 neighbors are using different Hold Times, the lowest Hold Time is used by the neighbors. If the Hold Time expires, the BGP4 router closes its TCP connection to the neighbor and clears any information it has learned from the neighbor and cached.

You can configure the Hold Time to be 0, in which case a BGP4 router will consider its

neighbors to always be up. For directly-attached neighbors, you can configure the Brocade Layer 3 switch to immediately close the TCP connection to the neighbor and clear entries learned from an EBGp neighbor if the interface to that neighbor goes down. This capability is provided by the fast external fallover feature, which is disabled by default.

- **BGP Identifier** – The router ID. The BGP Identifier (router ID) identifies the BGP4 router to other BGP4 routers. Brocade Layer 3 switches use the same router ID for OSPF and BGP4. If you do not set a router ID, the software uses the IP address on the lowest numbered loopback interface configured on the router. If the Layer 3 switch does not have a loopback interface, the default router ID is the lowest numbered IP address configured on the device. For more information or to change the router ID, refer to [“Changing the router ID”](#) on page 976.
- **Parameter list** – An optional list of additional parameters used in peer negotiation with BGP4 neighbors.

UPDATE messages from BGP4 routers

After BGP4 neighbors establish a BGP4 connection over TCP and exchange their BGP4 routing tables, they do not send periodic routing updates. Instead, a BGP4 neighbor sends an update to its neighbor when it has a new route to advertise or routes have changed or become unfeasible. An UPDATE message can contain the following information:

- **Network Layer Reachability Information (NLRI)** – The mechanism by which BGP4 supports Classless Interdomain Routing (CIDR). An NLRI entry consists of an IP prefix that indicates a network being advertised by the UPDATE message. The prefix consists of an IP network number and the length of the network portion of the number. For example, an UPDATE message with the NLRI entry 192.215.129.0/18 indicates a route to IP network 192.215.129.0 with network mask 255.255.192.0. The binary equivalent of this mask is 18 consecutive one bits, thus “18” in the NLRI entry.
- **Path attributes** – Parameters that indicate route-specific information such as path information, route preference, next hop values, and aggregation information. BGP4 uses the path attributes to make filtering and routing decisions.
- **Unreachable routes** – A list of routes that have been in the sending router BGP4 table but are no longer feasible. The UPDATE message lists unreachable routes in the same format as new routes.

KEEPALIVE messages from BGP4 routers

BGP4 routers do not regularly exchange UPDATE messages to maintain the BGP4 sessions. For example, if a Layer 3 switch configured to perform BGP4 routing has already sent the latest route information to its peers in UPDATE messages, the router does not send more UPDATE messages. Instead, BGP4 routers send KEEPALIVE messages to maintain the BGP4 sessions. KEEPALIVE messages are 19 bytes long and consist only of a message header; they contain no routing data.

BGP4 routers send KEEPALIVE messages at a regular interval, the Keep Alive Time. The default Keep Alive Time on Brocade Layer 3 switches is 60 seconds.

A parameter related to the Keep Alive Time is the Hold Time. A BGP4 router Hold Time determines how many seconds the router will wait for a KEEPALIVE or UPDATE message from a BGP4 neighbor before deciding that the neighbor is dead. The Hold Time is negotiated when BGP4 routers exchange OPEN messages; the lower Hold Time is then used by both neighbors. For example, if

BGP4 Router A sends a Hold Time of 5 seconds and BGP4 Router B sends a Hold Time of 4 seconds, both routers use 4 seconds as the Hold Time for their BGP4 session. The default Hold Time is 180 seconds. Generally, the Hold Time is configured to three times the value of the Keep Alive Time.

If the Hold Time is 0, a BGP4 router assumes that its neighbor is alive regardless of how many seconds pass between receipt of UPDATE or KEEPALIVE messages.

NOTIFICATION messages from BGP4 routers

When you close the router BGP4 session with a neighbor, or the router detects an error in a message received from the neighbor, or an error occurs on the router, the router sends a NOTIFICATION message to the neighbor. No further communication takes place between the BGP4 router that sent the NOTIFICATION and the neighbors that received the NOTIFICATION.

BGP4 graceful restart

BGP4 graceful restart is a high-availability routing feature that minimizes disruption in traffic forwarding, diminishes route flapping, and provides continuous service during a system restart, switchover, failover, or hitless OS upgrade. During such events, routes remain available between devices. BGP4 graceful restart operates between a device and its peers, and must be configured on each participating device.

Under normal operation, when a BGP4 device is restarted, the network is automatically reconfigured. Routes available through the restarting device are deleted when the device goes down, and are then rediscovered and added back to the routing tables when the device is back up and running. In a network with devices that are regularly restarted, performance can degrade significantly and the availability of network resources can be limited.

BGP4 graceful restart is enabled globally by default. A BGP4 graceful restart-enabled device advertises this capability to establish peering relationships with other devices. When a restart begins, neighbor devices mark all of the routes from the restarting device as stale, but continue to use the routes for the length of time specified by the restart timer. After the device is restarted, it begins to receive routing updates from the peers. When it receives the end-of-RIB marker that indicates it has received all of the BGP4 route updates, it recomputes the new routes and replaces the stale routes in the route map with the newly computed routes. If the device does not come back up within the time configured for the purge timer, the stale routes are removed.

NOTE

BGP4 graceful restart is supported in FSX 800 and FSX 1600 Layer 3 switches with dual management modules as well as in FCX switches in a stack. If the switch will function as a restart helper device only, a secondary management module is not required.

This implementation of BGP4 graceful restart supports the Internet Draft-ietf-idr-restart-10.txt: restart mechanism for BGP4

For details concerning configuration of BGP4 graceful restart, refer to [“Configuring BGP4 graceful restart”](#) on page 1385.

Basic configuration and activation for BGP4

BGP4 is disabled by default. Follow the steps below to enable BGP4 and place your Brocade Layer 3 switch into service as a BGP4 router.

1. Enable the BGP4 protocol.
2. Set the local AS number.

NOTE

You must specify the local AS number for BGP4 to become functional.

3. Add each BGP4 neighbor (peer BGP4 router) and identify the AS the neighbor is in.
4. Save the BGP4 configuration information to the system configuration file.

NOTE

By default, the Brocade router ID is the IP address configured on the lowest numbered loopback interface. If the Layer 3 switch does not have a loopback interface, the default router ID is the lowest numbered IP interface address configured on the device. For more information or to change the router ID, refer to [“Changing the router ID”](#) on page 976. If you change the router ID, all current BGP4 sessions are cleared.

```
Brocade> enable
Brocade#configure terminal
Brocade(config)#router bgp
BGP4: Please configure 'local-as' parameter in order to enable BGP4.
Brocade(config-bgp-router)#local-as 10
Brocade(config-bgp-router)#neighbor 209.157.23.99 remote-as 100
Brocade(config-bgp-router)#write memory
```

NOTE

When BGP4 is enabled on a Brocade Layer 3 switch, you do not need to reset the system. The protocol is activated as soon as you enable it. Moreover, the router begins a BGP4 session with a BGP4 neighbor as soon as you add the neighbor.

Note regarding disabling BGP4

If you disable BGP4, the Layer 3 switch removes all the running configuration information for the disabled protocol from the running-config. To restore the BGP4 configuration, you must reload the software to load the configuration from the startup-config. Moreover, when you save the configuration to the startup-config file after disabling the protocol, all the configuration information for the disabled protocol is removed from the startup-config file.

The CLI displays a warning message such as the following.

```
Brocade(config-bgp-router)#no router bgp
router bgp mode now disabled. All bgp config data will be lost when writing to
flash!
```

If you are testing a BGP4 configuration and are likely to disable and re-enable the protocol, you might want to make a backup copy of the startup-config file containing the protocol configuration information. This way, if you remove the configuration information by saving the configuration after disabling the protocol, you can restore the configuration by copying the backup copy of the startup-config file onto the flash memory.

NOTE

To disable BGP4 without losing the BGP4 configuration information, remove the local AS (for example, by entering the **no local-as <num>** command). In this case, BGP4 retains the other configuration information but is not operational until you set the local AS again.

BGP4 parameters

You can modify or set the following BGP4 parameters:

- Optional – Define the router ID. (The same router ID also is used by OSPF.)
- Required – Specify the local AS number.
- Optional – Add a loopback interface for use with neighbors.
- Required – Identify BGP4 neighbors.
- Optional – Change the Keep Alive Time and Hold Time.
- Optional – Change the update timer for route changes.
- Optional – Enable fast external fallover.
- Optional – Specify a list of individual networks in the local AS to be advertised to remote autonomous systems using BGP4.
- Optional – Change the default local preference for routes.
- Optional – Enable the default route (default-information-originate).
- Optional – Enable use of a default route to resolve a BGP4 next-hop route.
- Optional – Change the default MED (metric).
- Optional – Enable next-hop recursion.
- Optional – Change the default administrative distances for EBGp, IBGP, and locally originated routes.
- Optional – Require the first AS in an Update from an EBGp neighbor to be the neighbor AS.
- Optional – Change MED comparison parameters.
- Optional – Disable comparison of the AS-Path length.
- Optional – Enable comparison of the router ID.
- Optional – Enable auto summary to summarize routes at an IP class boundary (A, B, or C).
- Optional – Aggregate routes in the BGP4 route table into CIDR blocks.
- Optional – Configure the router as a BGP4 router reflector.
- Optional – Configure the Layer 3 switch as a member of a BGP4 confederation.
- Optional – Change the default metric for routes that BGP4 redistributes into RIP or OSPF.
- Optional – Change the parameters for RIP, OSPF, or static routes redistributed into BGP4.
- Optional – Change the number of paths for BGP4 load sharing.
- Optional – Change other load-sharing parameters
- Optional – Define BGP4 address filters.
- Optional – Define BGP4 AS-path filters.
- Optional – Define BGP4 community filters.
- Optional – Define IP prefix lists.

- Optional – Define neighbor distribute lists.
- Optional – Define BGP4 route maps for filtering routes redistributed into RIP and OSPF.
- Optional – Define route flap dampening parameters.

NOTE

When using the CLI, you set global level parameters at the BGP CONFIG level of the CLI. You can reach the BGP CONFIG level by entering **router bgp...** at the global CONFIG level.

BGP4 parameter changes

Some parameter changes take effect immediately while others do not take full effect until the router sessions with its neighbors are reset. Some parameters do not take effect until the router is rebooted.

Parameter changes that take effect immediately

- Enable or disable BGP.
- Set or change the local AS.
- Add neighbors.
- Change the update timer for route changes.
- Disable or enable fast external fallover.
- Specify individual networks that can be advertised.
- Change the default local preference, default information originate setting, or administrative distance.
- Enable or disable use of a default route to resolve a BGP4 next-hop route.
- Enable or disable MED (metric) comparison.
- Require the first AS in an Update from an EBGp neighbor to be the neighbor AS.
- Change MED comparison parameters.
- Disable comparison of the AS-Path length.
- Enable comparison of the router ID.
- Enable next-hop recursion.
- Enable or disable auto summary.
- Change the default metric.
- Disable or re-enable route reflection.
- Configure confederation parameters.
- Disable or re-enable load sharing.
- Change the maximum number of load-sharing paths.
- Change other load-sharing parameters.
- Define route flap dampening parameters.
- Add, change, or negate redistribution parameters (except changing the default MED; see below).
- Add, change, or negate route maps (when used by the **network** command or a redistribution command).

BGP4 parameter changes after resetting neighbor sessions

The following parameter changes take effect only after the router BGP4 sessions are cleared, or reset using the “soft” clear option. (Refer to [“Closing or resetting a neighbor session”](#) on page 1457.)

The parameter are as follows:

- Change the Hold Time or Keep Alive Time.
- Aggregate routes.
- Add, change, or negate filter tables.

BGP4 parameter changes after disabling and re-enabling redistribution

The following parameter change takes effect only after you disable and then re-enable redistribution:

- Change the default MED (metric).

BGP4 memory considerations

BGP4 handles a very large number of routes and therefore requires a lot of memory. For example, in a typical configuration with just a single BGP4 neighbor, a BGP4 router may need to be able to hold up to 80,000 routes. Many configurations, especially those involving more than one neighbor, can require the router to hold even more routes. Brocade Layer 3 switches provide dynamic memory allocation for BGP4 data. These devices automatically allocate memory when needed to support BGP4 neighbors, routes, and route attribute entries. Dynamic memory allocation is performed automatically by the software and does not require a reload.

[Table 239](#) lists the maximum total amount of system memory (DRAM) BGP4 can use. The maximum depends on the total amount of system memory on the device.

TABLE 239 Maximum memory usage

Platform	Maximum memory BGP4 can use
FESX with 128 MB	30 MB
FSX with Management 1 module with 256 MB	130 MB
FSX with Management 2 module with 512 MB	400 MB

The memory amounts listed in the table are for all BGP4 data, including routes received from neighbors, BGP route advertisements (routes sent to neighbors), and BGP route attribute entries. The routes sent to and received from neighbors use the most BGP4 memory. Generally, the actual limit to the number of neighbors, routes, or route attribute entries the device can accommodate depends on how many routes the Layer 3 switch sends to and receives from the neighbors.

In some cases, where most of the neighbors do not send or receive a full BGP route table (about 80,000 routes), the memory can support a larger number of BGP4 neighbors. However, if most of the BGP4 neighbors send or receive full BGP route tables, the number of BGP neighbors the memory can support is less than in configurations where the neighbors send smaller route tables.

As a guideline, Layer 3 switches with a 512 MB Management 4 module can accommodate 150 through 200 neighbors, with the assumption that the Layer 3 switch receives about one million routes total from all neighbors and sends about eight million routes total to neighbors. For each additional one million incoming routes, the capacity for outgoing routes decreases by around two million.

Memory configuration options obsoleted by dynamic memory

Devices that support dynamic BGP4 memory allocation do not require or even support static configuration of memory for BGP4 neighbors, routes, or route attributes. Consequently, the following CLI commands and equivalent Web management options are not supported on these devices:

- **max-neighbors** *<num>*
- **max-routes** *<num>*
- **max-attribute-entries** *<num>*

If you boot a device that has a startup-config file that contains these commands, the software ignores the commands and uses dynamic memory allocation for BGP4. The first time you save the device running configuration (running-config) to the startup-config file, the commands are removed from the file.

Basic configuration tasks required for BGP4

The following sections describe how to perform the configuration tasks that are required to use BGP4 on the Brocade Layer 3 switch. You can modify many parameters in addition to the ones described in this section. Refer to [“Optional BGP4 configuration tasks”](#) on page 1365.

Enabling BGP4 on the router

When you enable BGP4 on the router, BGP4 is automatically activated. To enable BGP4 on the router, enter the following commands.

```
Brocade> enable
Brocade#configure terminal
Brocade(config)#router bgp
BGP4: Please configure 'local-as' parameter in order to enable BGP4.
Brocade(config-bgp-router)#local-as 10
Brocade(config-bgp-router)#neighbor 209.157.23.99 remote-as 100
Brocade(config-bgp-router)#write memory
```

Changing the router ID

The OSPF and BGP4 protocols use router IDs to identify the routers that are running the protocols. A router ID is a valid, unique IP address and sometimes is an IP address configured on the router. The router ID cannot be an IP address in use by another device.

By default, the router ID on a Brocade Layer 3 switch is one of the following:

- If the router has loopback interfaces, the default router ID is the IP address configured on the lowest numbered loopback interface configured on the Layer 3 switch. For example, if you configure loopback interfaces 1, 2, and 3 as follows, the default router ID is 9.9.9.9/24:
 - Loopback interface 1, 9.9.9.9/24
 - Loopback interface 2, 4.4.4.4/24
 - Loopback interface 3, 1.1.1.1/24
- If the device does not have any loopback interfaces, the default router ID is the lowest numbered IP interface address configured on the device.

NOTE

Brocade Layer 3 switches use the same router ID for both OSPF and BGP4. If the router is already configured for OSPF, you may want to use the router ID that is already in use on the router rather than set a new one. To display the router ID, enter the **show ip** CLI command at any CLI level.

To change the router ID, enter a command such as the following.

```
Brocade(config)#ip router-id 209.157.22.26
```

Syntax: **ip router-id** <ip-addr>

The <ip-addr> can be any valid, unique IP address.

NOTE

You can specify an IP address used for an interface on the Brocade Layer 3 switch, but do not specify an IP address in use by another device.

Setting the local AS number

The local AS number identifies the AS the Brocade BGP4 router is in. The AS number can be from 1 through 65535. There is no default. AS numbers 64512 through 65535 are the well-known private BGP4 AS numbers and are not advertised to the Internet community.

To set the local AS number, enter commands such as the following.

```
Brocade(config)#router bgp
BGP4: Please configure 'local-as' parameter in order to enable BGP4.
Brocade(config-bgp-router)#local-as 10
Brocade(config-bgp-router)#write memory
```

Syntax: **[no] local-as** <num>

The <num> parameter specifies the local AS number.

Adding a loopback interface

You can configure the router to use a loopback interface instead of a specific port or virtual routing interface to communicate with a BGP4 neighbor. A loopback interface adds stability to the network by working around route flap problems that can occur due to unstable links between the router and its neighbors.

Loopback interfaces are always up, regardless of the states of physical interfaces. Loopback interfaces are especially useful for IBGP neighbors (neighbors in the same AS) that are multiple hops away from the router. When you configure a BGP4 neighbor on the router, you can specify whether the router uses the loopback interface to communicate with the neighbor. As long as a path exists between the router and its neighbor, BGP4 information can be exchanged. The BGP4 session is not associated with a specific link but instead is associated with the virtual interfaces.

You can add up to 24 IP addresses to each loopback interface.

NOTE

If you configure the Brocade Layer 3 switch to use a loopback interface to communicate with a BGP4 neighbor, the peer IP address on the remote router pointing to your loopback address must be configured.

To add a loopback interface, enter commands such as those shown in the following example.

```
Brocade(config-bgp-router)#exit
Brocade(config)#int loopback 1
Brocade(config-lbif-1)#ip address 10.0.0.1/24
```

Syntax: `interface loopback <num>`

The <num> value can be from 1 through 8 on Chassis Layer 3 switches. The value can be from 1 through 4 on the Compact Layer 3 switch.

Adding BGP4 neighbors

The BGP4 protocol does not contain a peer discovery process. Therefore, for each of the router BGP4 neighbors (peers), you must indicate the neighbor IP address and the AS each neighbor is in. Neighbors that are in different autonomous systems communicate using EBGP. Neighbors within the same AS communicate using IBGP.

NOTE

If the Layer 3 switch has multiple neighbors with similar attributes, you can simplify configuration by configuring a peer group, then adding individual neighbors to it. The configuration steps are similar, except you specify a peer group name instead of a neighbor IP address when configuring the neighbor parameters, then add individual neighbors to the peer group. Refer to [“Adding a BGP4 peer group”](#) on page 1361.

NOTE

The Layer 3 switch attempts to establish a BGP4 session with a neighbor as soon as you enter a command specifying the neighbor IP address. If you want to completely configure the neighbor parameters before the Layer 3 switch establishes a session with the neighbor, you can administratively shut down the neighbor. Refer to [“Administratively shutting down a session with a BGP4 neighbor”](#) on page 1364.

To add a BGP4 neighbor with IP address 209.157.22.26, enter the following command.

```
Brocade(config-bgp-router)#neighbor 209.157.22.26
```

The neighbor <ip-addr> must be a valid IP address.

The **neighbor** command has some additional parameters, as shown in the following syntax:

Syntax: `[no] neighbor <ip-addr> | <peer-group-name>
[advertisement-interval <num>]`

```

[capability orf prefixlist [send | receive]]
[default-originate [route-map <map-name>]]
[description <string>]
[distribute-list in | out <num,num,...> | <ACL-num> in | out]
[ebgp-multihop [<num>]]
[filter-list in | out <num,num,...> | <ACL-num> in | out | weight]
[maximum-prefix <num> [<threshold>] [teardown]]
[next-hop-self]
[nlri multicast | unicast | multicast unicast]
[password [0 | 1] <string>]
[prefix-list <string> in | out]
[remote-as <as-number>]
[remove-private-as]
[route-map in | out <map-name>]
[route-reflector-client]
[send-community]
[soft-reconfiguration inbound]
[shutdown]
[timers keep-alive <num> hold-time <num>]
[unsuppress-map <map-name>]
[update-source <ip-addr> | ethernet <port> | loopback <num> | ve <num>]
[weight <num>]

```

The `<ip-addr> | <peer-group-name>` parameter indicates whether you are configuring an individual neighbor or a peer group. If you specify a neighbor IP address, you are configuring that individual neighbor. If you specify a peer group name, you are configuring a peer group. Refer to [“Adding a BGP4 peer group”](#) on page 1361.

advertisement-interval `<num>` specifies the minimum delay (in seconds) between messages to the specified neighbor. The default is 30 for EBGp neighbors (neighbors in other autonomous systems). The default is 5 for IBGP neighbors (neighbors in the same AS). The range is 0 through 600.

NOTE

The Layer 3 switch applies the advertisement interval only under certain conditions. The Layer 3 switch does not apply the advertisement interval when sending initial updates to a BGP4 neighbor. As a result, the Layer 3 switch sends the updates one immediately after another, without waiting for the advertisement interval.

capability orf prefixlist `[send | receive]` configures cooperative router filtering. The **send | receive** parameter specifies the support you are enabling:

- **send** – The Layer 3 switch sends the IP prefix lists as Outbound Route Filters (ORFs) to the neighbor.
- **receive** – The Layer 3 switch accepts filters as Outbound Route Filters (ORFs) from the neighbor.

If you do not specify the capability, both capabilities are enabled. The **prefixlist** parameter specifies the type of filter you want to send to the neighbor.

For more information, refer to [“Configuring cooperative BGP4 route filtering”](#) on page 1411.

NOTE

The current release supports cooperative filtering only for filters configured using IP prefix lists.

default-originate [**route-map** <map-name>] configures the Layer 3 switch to send the default route 0.0.0.0 to the neighbor. If you use the route-map <map-name> parameter, the route map injects the default route conditionally, based on the match conditions in the route map.

description <string> specifies a name for the neighbor. You can enter an alphanumeric text string up to 80 characters long.

distribute-list in | out <num,num,...> specifies a distribute list to be applied to updates to or from the specified neighbor. The **in | out** keyword specifies whether the list is applied on updates received from the neighbor or sent to the neighbor. The <num,num,...> parameter specifies the list of address-list filters. The router applies the filters in the order in which you list them and stops applying the filters in the distribute list when a match is found.

Alternatively, you can specify **distribute-list** <ACL-num> **in | out** to use an IP ACL instead of a distribute list. In this case, <ACL-num> is an IP ACL.

NOTE

By default, if a route does not match any of the filters, the Layer 3 switch denies the route. To change the default behavior, configure the last filter as “permit any any”.

NOTE

The address filter must already be configured. Refer to [“Specific IP address filtering”](#) on page 1394.

ebgp-multihop [<num>] specifies that the neighbor is more than one hop away and that the session type with the neighbor is thus EBGp-multihop. This option is disabled by default. The <num> parameter specifies the TTL you are adding for the neighbor. You can specify a number from 0 through 255. The default is 0. If you leave the EBGp TTL value set to 0, the software uses the IP TTL value.

filter-list in | out <num,num,...> specifies an AS-path filter list or a list of AS-path ACLs. The **in | out** keyword specifies whether the list is applied on updates received from the neighbor or sent to the neighbor. If you specify in or out, The <num,num,...> parameter specifies the list of AS-path filters. The router applies the filters in the order in which you list them and stops applying the filters in the AS-path filter list when a match is found. The **weight** <num> parameter specifies a weight that the Layer 3 switch applies to routes received from the neighbor that match the AS-path filter or ACL. You can specify a number from 0 through 65535.

Alternatively, you can specify filter-list <ACL-num> **in | out | weight** to use an AS-path ACL instead of an AS-path filter list. In this case, <ACL-num> is an AS-path ACL.

NOTE

By default, if an AS-path does not match any of the filters or ACLs, the Layer 3 switch denies the route. To change the default behavior, configure the last filter or ACL as “permit any any”.

NOTE

The AS-path filter or ACL must already be configured. Refer to [“AS-path filtering”](#) on page 1395.

maximum-prefix <num> specifies the maximum number of IP network prefixes (routes) that can be learned from the specified neighbor or peer group. You can specify a value from 0 through 4294967295. The default is 0 (unlimited):

- The <num> parameter specifies the maximum number. You can specify a value from 0 through 4294967295. The default is 0 (unlimited).

- The **<threshold>** parameter specifies the percentage of the value you specified for the **maximum-prefix <num>**, at which you want the software to generate a Syslog message. You can specify a value from 1 (one percent) to 100 (100 percent). The default is 100.
- The **teardown** parameter tears down the neighbor session if the maximum-prefix limit is exceeded. The session remains shutdown until you clear the prefixes using the **clear ip bgp neighbor all** or **clear ip bgp neighbor <ip-addr>** command, or change the neighbor maximum-prefix configuration. The software also generates a Syslog message.

next-hop-self specifies that the router should list itself as the next hop in updates sent to the specified neighbor. This option is disabled by default.

The **nlri multicast | unicast | multicast** unicast parameter specifies whether the neighbor is a multicast neighbor or a unicast neighbor. Optionally, you also can specify unicast if you want the Layer 3 switch to exchange unicast (BGP4) routes as well as multicast routes with the neighbor. The default is unicast only.

password [0 | 1] <string> specifies an MD5 password for securing sessions between the Layer 3 switch and the neighbor. You can enter a string up to 80 characters long. The string can contain any alphanumeric characters, but the first character cannot be a number. If the password contains a number, do not enter a space following the number.

The **0 | 1** parameter is the encryption option, which you can omit (the default) or which can be one of the following:

- **0** – Disables encryption for the authentication string you specify with the command. The password or string is shown as clear text in the output of commands that display neighbor or peer group configuration information.
- **1** – Assumes that the authentication string you enter is the encrypted form, and decrypts the value before using it.

For more information, refer to [“Encryption of BGP4 MD5 authentication keys”](#) on page 1359.

NOTE

If you want the software to assume that the value you enter is the clear-text form, and to encrypt display of that form, do not enter 0 or 1. Instead, omit the encryption option and allow the software to use the default behavior.

If you specify encryption option 1, the software assumes that you are entering the encrypted form of the password or authentication string. In this case, the software decrypts the password or string you enter before using the value for authentication. If you accidentally enter option 1 followed by the clear-text version of the password or string, authentication will fail because the value used by the software will not match the value you intended to use.

prefix-list <string> in | out specifies an IP prefix list. You can use IP prefix lists to control routes to and from the neighbor. IP prefix lists are an alternative method to AS-path filters. The **in | out** keyword specifies whether the list is applied on updates received from the neighbor or sent to the neighbor. You can configure up to 1000 prefix list filters. The filters can use the same prefix list or different prefix lists. To configure an IP prefix list, refer to [“Defining IP prefix lists”](#) on page 1401.

remote-as <as-number> specifies the AS the remote neighbor is in. The **<as-number>** can be a number from 1 through 65535. There is no default.

remove-private-as configures the router to remove private AS numbers from UPDATE messages the router sends to this neighbor. The router will remove AS numbers 64512 through 65535 (the well-known BGP4 private AS numbers) from the AS-path attribute in UPDATE messages the Layer 3 switch sends to the neighbor. This option is disabled by default.

route-map in | out <map-name> specifies a route map the Layer 3 switch will apply to updates sent to or received from the specified neighbor. The **in | out** keyword specifies whether the list is applied on updates received from the neighbor or sent to the neighbor.

NOTE

The route map must already be configured. Refer to [“Defining route maps”](#) on page 1403.

route-reflector-client specifies that this neighbor is a route-reflector client of the router. Use the parameter only if this router is going to be a route reflector. For information, refer to [“Route reflection parameter configuration”](#) on page 1378. This option is disabled by default.

send-community enables sending the community attribute in updates to the specified neighbor. By default, the router does not send the community attribute.

shutdown administratively shuts down the session with this neighbor. Shutting down the session allows you to completely configure the neighbor and save the configuration without actually establishing a session with the neighbor. This option is disabled by default.

soft-reconfiguration inbound enables the soft reconfiguration feature, which stores all the route updates received from the neighbor. If you request a soft reset of inbound routes, the software performs the reset by comparing the policies against the stored route updates, instead of requesting the neighbor BGP4 route table or resetting the session with the neighbor. Refer to [“Using soft reconfiguration”](#) on page 1452.

timers keep-alive <num> **hold-time** <num> overrides the global settings for the Keep Alive Time and Hold Time. For the Keep Alive Time, you can specify from 0 through 65535 seconds. For the Hold Time, you can specify 0 or 3 through 65535 (1 and 2 are not allowed). If you set the Hold Time to 0, the router waits indefinitely for messages from a neighbor without concluding that the neighbor is dead. The defaults for these parameters are the currently configured global Keep Alive Time and Hold Time. For more information about these parameters, refer to [“Changing the Keep Alive Time and Hold Time”](#) on page 1365.

unsuppress-map <map-name> removes route dampening from a neighbor routes when those routes have been dampened due to aggregation. Refer to [“Removing route dampening from a neighbor routes suppressed due to aggregation”](#) on page 1418.

update-source <ip-addr> | **ethernet** <port> | **loopback** <num> | **ve** <num> configures the router to communicate with the neighbor through the specified interface. There is no default.

weight <num> specifies a weight the Layer 3 switch will add to routes received from the specified neighbor. BGP4 prefers larger weights over smaller weights. The default weight is 0.

Encryption of BGP4 MD5 authentication keys

When you configure a BGP4 neighbor or neighbor peer group, you can specify an MD5 authentication string for authenticating packets exchanged with the neighbor or peer group of neighbors.

For added security, the software encrypts display of the authentication string by default. The software also provides an optional parameter to disable encryption of the authentication string, on an individual neighbor or peer group basis. By default, the MD5 authentication strings are displayed in encrypted format in the output of the following commands:

- **show running-config** (or **write terminal**)
- **show configuration**
- **show ip bgp config**

When encryption of the authentication string is enabled, the string is encrypted in the CLI regardless of the access level you are using.

If you display the running-config after reloading, the BGP4 commands that specify an authentication string show the string in encrypted form.

In addition, when you save the configuration to the startup-config file, the file contains the new BGP4 command syntax and encrypted passwords or strings.

NOTE

Brocade recommends that you save a copy of the startup-config file for each switch you plan to upgrade.

Encryption example

The following commands configure a BGP4 neighbor and a peer group, and specify MD5 authentication strings (passwords) for authenticating packets exchanged with the neighbor or peer group.

```
Brocade(config-bgp-router)#local-as 2
Brocade(config-bgp-router)#neighbor xyz peer-group
Brocade(config-bgp-router)#neighbor xyz password abc
Brocade(config-bgp-router)#neighbor 10.10.200.102 peer-group xyz
Brocade(config-bgp-router)#neighbor 10.10.200.102 password test
```

Here is how the commands appear when you display the BGP4 configuration commands.

```
Brocade#show ip bgp config
Current BGP configuration:
router bgp
  local-as 2
  neighbor xyz peer-group
  neighbor xyz password 1 $!2d
  neighbor 10.10.200.102 peer-group xyz
  neighbor 10.10.200.102 remote-as 1
  neighbor 10.10.200.102 password 1 $on-o
```

Notice that the software has converted the commands that specify an authentication string into the new syntax (described below), and has encrypted display of the authentication strings.

Command syntax

Since the default behavior does not affect the BGP4 configuration itself but does encrypt display of the authentication string, the CLI does not list the encryption options.

Syntax: `[no] neighbor <ip-addr> | <peer-group-name> password [0 | 1] <string>`

The `<ip-addr> | <peer-group-name>` parameter indicates whether you are configuring an individual neighbor or a peer group. If you specify a neighbor IP address, you are configuring that individual neighbor. If you specify a peer group name, you are configuring a peer group.

The **password** `<string>` parameter specifies an MD5 authentication string for securing sessions between the Layer 3 switch and the neighbor. You can enter a string up to 80 characters long. The string can contain any alphanumeric characters, but the first character cannot be a number. If the password contains a number, do not enter a space following the number.

The **0 | 1** parameter is the encryption option, which you can omit (the default) or which can be one of the following:

- **0** – Disables encryption for the authentication string you specify with the command. The password or string is shown as clear text in the output of commands that display neighbor or peer group configuration information.
- **1** – Assumes that the authentication string you enter is the encrypted form, and decrypts the value before using it.

NOTE

If you want the software to assume that the value you enter is the clear-text form, and to encrypt display of that form, do not enter 0 or 1. Instead, omit the encryption option and allow the software to use the default behavior.

If you specify encryption option 1, the software assumes that you are entering the encrypted form of the password or authentication string. In this case, the software decrypts the password or string you enter before using the value for authentication. If you accidentally enter option 1 followed by the clear-text version of the password or string, authentication will fail because the value used by the software will not match the value you intended to use.

Displaying the Authentication String

If you want to display the authentication string, enter the following commands.

```
Brocade(config)#enable password-display
Brocade#show ip bgp neighbors
```

The **enable password-display** command enables display of the authentication string, but only in the output of the **show ip bgp neighbors** command. Display of the string is still encrypted in the startup-config file and running-config. Enter the command at the global CONFIG level of the CLI.

NOTE

The command also displays SNMP community strings in clear text, in the output of the **show snmp server** command.

Adding a BGP4 peer group

A **peer group** is a set of BGP4 neighbors that share common parameters. Peer groups provide the following benefits:

- **Simplified neighbor configuration** – You can configure a set of neighbor parameters and then apply them to multiple neighbors. You do not need to individually configure the common parameters individually on each neighbor.
- **Flash memory conservation** – Using peer groups instead of individually configuring all the parameters for each neighbor requires fewer configuration commands in the startup-config file.

You can perform the following tasks on a peer-group basis:

- Reset neighbor sessions
- Perform soft-outbound resets (the Layer 3 switch updates outgoing route information to neighbors but does not entirely reset the sessions with those neighbors)
- Clear BGP message statistics
- Clear error buffers

Peer group parameters

You can set all neighbor parameters in a peer group. When you add a neighbor to the peer group, the neighbor receives all the parameter settings you set in the group, except parameter values you have explicitly configured for the neighbor. If you do not set a neighbor parameter in the peer group and the parameter also is not set for the individual neighbor, the neighbor uses the default value.

Peer group configuration rules

The following rules apply to peer group configuration:

- You must configure a peer group before you can add neighbors to the peer group.
- If you remove a parameter from a peer group, the value for that parameter is reset to the default for all the neighbors within the peer group, unless you have explicitly set that parameter on individual neighbors. In this case, the value you set on the individual neighbors applies to those neighbors, while the default value applies to neighbors for which you have not explicitly set the value.

NOTE

If you enter a command to remove the remote AS parameter from a peer group, the software checks to ensure that the peer group does not contain any neighbors. If the peer group does contain neighbors, the software does not allow you to remove the remote AS. The software prevents removing the remote AS in this case so that the neighbors in the peer group that are using the remote AS do not lose connectivity to the Layer 3 switch.

- Once you add a neighbor to a peer group, you cannot configure the following outbound parameters (the parameters governing outbound traffic) for the neighbor:
 - Default-information-originate
 - Next-hop-self
 - Outbound route map
 - Outbound filter list

- Outbound distribute list
- Outbound prefix list
- Remote AS, if configured for the peer group
- Remove private AS
- Route reflector client
- Send community
- Timers
- Update source

If you want to change an outbound parameter for an individual neighbor, you must first remove the neighbor from the peer group. In this case, you cannot re-add the neighbor to the same peer group, but you can add the neighbor to a different peer group. All the neighbors within a peer group must have the same values for the outbound parameters. To change an outbound parameter to the same value for all neighbors within a peer group, you can change the parameter on a peer-group basis. In this case, you do not need to remove the neighbors and change the parameter individually for each neighbor.

- If you add an outbound parameter to a peer group, that parameter is automatically applied to all neighbors within the peer group.
- When you add a neighbor to a peer group, the software removes any outbound parameters for that neighbor from the running configuration (running-config). As a result, when you save the configuration to the startup-config file, the file does not contain any outbound parameters for the individual neighbors you have placed in a peer group. The only outbound parameters the startup-config file contains for neighbors within a peer group are the parameters associated with the peer group itself. However, the running-config and the startup-config file can contain individual parameters listed in the previous section as well as the settings for those parameters within a peer group.

You can override neighbor parameters that do not affect outbound policy on an individual neighbor basis.

- If you do not specify a parameter for an individual neighbor, the neighbor uses the value in the peer group.
- If you set the parameter for the individual neighbor, that value overrides the value you set in the peer group.
- If you add a parameter to a peer group that already contains neighbors, the parameter value is applied to neighbors that do not already have the parameter explicitly set. If a neighbor has the parameter explicitly set, the explicitly set value overrides the value you set for the peer group.
- If you remove the setting for a parameter from a peer group, the value for that parameter changes to the default value for all the neighbors in the peer group that do not have that parameter individually set.

Configuring a peer group

To configure a BGP4 peer group, enter commands such as the following at the BGP configuration level.

```
Brocade(config-bgp-router)#neighbor PeerGroup1 peer-group
Brocade(config-bgp-router)#neighbor PeerGroup1 description "EastCoast Neighbors"
Brocade(config-bgp-router)#neighbor PeerGroup1 remote-as 100
Brocade(config-bgp-router)#neighbor PeerGroup1 distribute-list out 1
```

The commands in this example configure a peer group called “PeerGroup1” and set the following parameters for the peer group:

- A description, “EastCoast Neighbors”
- A remote AS number, 100
- A distribute list for outbound traffic

The software applies these parameters to each neighbor you add to the peer group. You can override the description parameter for individual neighbors. If you set the description parameter for an individual neighbor, the description overrides the description configured for the peer group. However, you cannot override the remote AS and distribute list parameters for individual neighbors. Since these parameters control outbound traffic, the parameters must have the same values for all neighbors within the peer group.

Syntax: `neighbor <peer-group-name> peer-group`

The `<peer-group-name>` parameter specifies the name of the group and can be up to 80 characters long. The name can contain special characters and internal blanks. If you use internal blanks, you must use quotation marks around the name. For example, the command **neighbor “My Three Peers” peer-group** is valid, but the command **neighbor My Three Peers peer-group** is not valid.

Syntax: `[no] neighbor <ip-addr> | <peer-group-name>`
`[advertisement-interval <num>]`
`[default-originate [route-map <map-name>]]`
`[description <string>]`
`[distribute-list in | out <num,num,...> | <ACL-num> in | out]`
`[ebgp-multihop [<num>]]`
`[filter-list in | out <num,num,...> | <ACL-num> in | out | weight]`
`[maximum-prefix <num> [<threshold>] [teardown]]`
`[next-hop-self]`
`[password [0 | 1] <string>]`
`[prefix-list <string> in | out]`
`[remote-as <as-number>]`
`[remove-private-as]`
`[route-map in | out <map-name>]`
`[route-reflector-client]`
`[send-community]`
`[soft-reconfiguration inbound]`
`[shutdown]`
`[timers keep-alive <num> hold-time <num>]`
`[update-source loopback <num>]`
`[weight <num>]`

The `<ip-addr> | <peer-group-name>` parameter indicates whether you are configuring a peer group or an individual neighbor. You can specify a peer group name or IP address with the **neighbor** command. If you specify a peer group name, you are configuring a peer group. If you specify a neighbor IP address, you are configuring that individual neighbor. Use the `<ip-addr>` parameter if you are configuring an individual neighbor instead of a peer group. Refer to [“Adding BGP4 neighbors”](#) on page 1354.

The remaining parameters are the same ones supported for individual neighbors. Refer to [“Adding BGP4 neighbors”](#) on page 1354.

Applying a peer group to a neighbor

After you configure a peer group, you can add neighbors to the group. When you add a neighbor to a peer group, you are applying all the neighbor attributes specified in the peer group to the neighbor.

To add neighbors to a peer group, enter commands such as the following.

```
Brocade(config-bgp-router)#neighbor 192.168.1.12 peer-group PeerGroup1
Brocade(config-bgp-router)#neighbor 192.168.2.45 peer-group PeerGroup1
Brocade(config-bgp-router)#neighbor 192.168.3.69 peer-group PeerGroup1
```

The commands in this example add three neighbors to the peer group “PeerGroup1”. As members of the peer group, the neighbors automatically receive the neighbor parameter values configured for the peer group. You also can override the parameters (except parameters that govern outbound traffic) on an individual neighbor basis. For neighbor parameters not specified for the peer group, the neighbors use the default values.

Syntax: `neighbor <ip-addr> peer-group <peer-group-name>`

The `<ip-addr>` parameter specifies the IP address of the neighbor.

The `<peer-group-name>` parameter specifies the peer group name.

NOTE

You must add the peer group before you can add neighbors to it.

Administratively shutting down a session with a BGP4 neighbor

You can prevent the Layer 3 switch from starting a BGP4 session with a neighbor by administratively shutting down the neighbor. This option is very useful for situations in which you want to configure parameters for a neighbor but are not ready to use the neighbor. You can shut the neighbor down as soon as you have added it the Layer 3 switch, configure the neighbor parameters, then allow the Layer 3 switch to re-establish a session with the neighbor by removing the shutdown option from the neighbor.

When you apply the new option to shut down a neighbor, the option takes place immediately and remains in effect until you remove the option. If you save the configuration to the startup-config file, the shutdown option remains in effect even after a software reload.

NOTE

The software also contains an option to end the session with a BGP4 neighbor and thus clear the routes learned from the neighbor. Unlike this clear option, the option for shutting down the neighbor can be saved in the startup-config file and thus can prevent the Layer 3 switch from establishing a BGP4 session with the neighbor even after reloading the software.

NOTE

If you notice that a particular BGP4 neighbor never establishes a session with the Brocade Layer 3 switch, check the Layer 3 switch running-config and startup-config files to see whether the configuration contains a command that is shutting down the neighbor. The neighbor may have been shut down previously by an administrator.

To shut down a BGP4 neighbor, enter commands such as the following.

```
Brocade(config)#router bgp
Brocade(config-bgp-router)#neighbor 209.157.22.26 shutdown
Brocade(config-bgp-router)#write memory
```

Syntax: [no] neighbor <ip-addr> shutdown

The <ip-addr> parameter specifies the IP address of the neighbor.

Optional BGP4 configuration tasks

The following sections describe how to perform optional BGP4 configuration tasks.

Changing the Keep Alive Time and Hold Time

The Keep Alive Time specifies how frequently the router will send KEEPALIVE messages to its BGP4 neighbors. The Hold Time specifies how long the router will wait for a KEEPALIVE or UPDATE message from a neighbor before concluding that the neighbor is dead. When the router concludes that a BGP4 neighbor is dead, the router ends the BGP4 session and closes the TCP connection to the neighbor.

The default Keep Alive time is 60 seconds. The default Hold Time is 180 seconds. To change the timers, use either of the following methods.

NOTE

Generally, you should set the Hold Time to three times the value of the Keep Alive Time.

NOTE

You can override the global Keep Alive Time and Hold Time on individual neighbors. Refer to [“Adding BGP4 neighbors”](#) on page 1354.

To change the Keep Alive Time to 30 and Hold Time to 90, enter the following command.

```
Brocade(config-bgp-router)#timers keep-alive 30 hold-time 90
```

Syntax: timers keep-alive <num> hold-time <num>

For each keyword, <num> indicates the number of seconds. The Keep Alive Time can be 0 through 65535. The Hold Time can be 0 or 3 through 65535 (1 and 2 are not allowed). If you set the Hold Time to 0, the router waits indefinitely for messages from a neighbor without concluding that the neighbor is dead.

Changing the BGP4 next-hop update timer

By default, the Layer 3 switch updates its BGP4 next-hop tables and affected BGP4 routes five seconds after IGP route changes. You can change the update timer to a value from 1 through 30 seconds.

To change the BGP4 update timer value, enter the **update-time** command at the BGP configuration level of the CLI.

```
Brocade(config-bgp-router)#update-time 15
```

This command changes the update timer to 15 seconds.

Syntax: `[no] update-time <secs>`

The `<secs>` parameter specifies the number of seconds and can be from 1 through 30. The default is 5.

Enabling fast external fallover

BGP4 routers rely on KEEPALIVE and UPDATE messages from neighbors to signify that the neighbors are alive. For BGP4 neighbors that are two or more hops away, such messages are the only indication that the BGP4 protocol has concerning the alive state of the neighbors. As a result, if a neighbor dies, the router will wait until the Hold Time expires before concluding that the neighbor is dead and closing its BGP4 session and TCP connection with the neighbor.

The router waits for the Hold Time to expire before ending the connection to a directly-attached BGP4 neighbor that dies.

For directly attached neighbors, the router immediately senses loss of a connection to the neighbor from a change of state of the port or interface that connects the router to its neighbor. For directly attached EBGP neighbors, the router can use this information to immediately close the BGP4 session and TCP connection to locally attached neighbors that die.

NOTE

The fast external fallover feature applies only to directly attached EBGP neighbors. The feature does not apply to IBGP neighbors.

If you want to enable the router to immediately close the BGP4 session and TCP connection to locally attached neighbors that die, use either of the following methods.

To enable fast external fallover, enter the following command.

```
Brocade(config-bgp-router)#fast-external-fallover
```

To disable fast external fallover again, enter the following command.

```
Brocade(config-bgp-router)#no fast-external-fallover
```

Syntax: `[no] fast-external-fallover`

Changing the maximum number of paths for BGP4 load sharing

Load sharing enables the Layer 3 switch to balance traffic to a route across multiple equal-cost paths of the same type (EBGP or IBGP) for the route.

To configure the Layer 3 switch to perform BGP4 load sharing:

- Enable IP load sharing if it is disabled.
- Set the maximum number of paths. The default maximum number of BGP4 load sharing paths is 1, which means no BGP4 load sharing takes place by default.

NOTE

The maximum number of BGP4 load sharing paths cannot be greater than the maximum number of IP load sharing paths.

How load sharing affects route selection

During evaluation of multiple paths to select the best path to a given destination for installment in the IP route table, the last comparison the Layer 3 switch performs is a comparison of the internal paths:

- When IP load sharing is disabled, the Layer 3 switch prefers the path to the router with the lower router ID.
- When IP load sharing and BGP4 load sharing are enabled, the Layer 3 switch balances the traffic across the multiple paths instead of choosing just one path based on router ID.

Refer to [“How BGP4 selects a path for a route”](#) on page 1344 for a description of the BGP4 algorithm.

When you enable IP load sharing, the Layer 3 switch can load balance BGP4 or OSPF routes across up to four equal paths by default. You can change the number of IP load sharing paths to a value from 2 through 6.

How load sharing works

Load sharing is performed in round-robin fashion and is based on the destination IP address only. The first time the router receives a packet destined for a specific IP address, the router uses a round-robin algorithm to select the path that was not used for the last newly learned destination IP address. Once the router associates a path with a particular destination IP address, the router will always use that path as long as the router contains the destination IP address in its cache.

NOTE

The Layer 3 switch does not perform source routing. The router is concerned only with the paths to the next-hop routers, not the entire paths to the destination hosts.

A BGP4 destination can be learned from multiple BGP4 neighbors, leading to multiple BGP4 paths to reach the same destination. Each of the paths may be reachable through multiple IGP paths (multiple OSPF or RIP paths). In this case, the software installs all the multiple equal-cost paths in the BGP4 route table, up to the maximum number of BGP4 equal-cost paths allowed. The IP load sharing feature then distributes traffic across the equal-cost paths to the destination.

If an IGP path used by a BGP4 next-hop route path installed in the IP route table changes, then the BGP4 paths and IP paths are adjusted accordingly. For example, if one of the OSPF paths to reach the BGP4 next hop goes down, the software removes this path from the BGP4 route table and the IP route table. Similarly, if an additional OSPF path becomes available to reach the BGP4 next-hop router for a particular destination, the software adds the additional path to the BGP4 route table and the IP route table.

Changing the maximum number of shared BGP4 paths

When IP load sharing is enabled, BGP4 can balance traffic to a specific destination across up to four equal paths. You can set the maximum number of paths to a value from 1 through 4. The default is 1.

NOTE

The maximum number of BGP4 load sharing paths cannot be greater than the maximum number of IP load sharing paths. To increase the maximum number of IP load sharing paths, use the **ip load sharing <num>** command at the global CONFIG level of the CLI.

To change the maximum number of shared paths, enter commands such as the following.

```
Brocade(config)#router bgp
Brocade(config-bgp-router)#maximum-paths 4
Brocade(config-bgp-router)#write memory
```

Syntax: [no] maximum-paths <num>

The <num> parameter specifies the maximum number of paths across which the Layer 3 switch can balance traffic to a given BGP4 destination. You can change the maximum number of paths to a value from 2 through 4. The default is 1.

Customizing BGP4 load sharing

By default, when BGP4 load sharing is enabled, both IBGP and EBGP paths are eligible for load sharing, while paths from different neighboring autonomous systems are not eligible. You can change load sharing to apply only to IBGP or EBGP paths, or to support load sharing among paths from different neighboring autonomous systems.

To enable load sharing of IBGP paths only, enter the following command at the BGP configuration level of the CLI.

```
Brocade(config-bgp-router)#multipath ibgp
```

To enable load sharing of EBGP paths only, enter the following command at the BGP configuration level of the CLI.

```
Brocade(config-bgp-router)#multipath ebgp
```

To enable load sharing of paths from different neighboring autonomous systems, enter the following command at the BGP configuration level of the CLI.

```
Brocade(config-bgp-router)#multipath multi-as
```

Syntax: [no] multipath ebgp | ibgp | multi-as

The **ebgp** | **ibgp** | **multi-as** parameter specifies the change you are making to load sharing:

- **ebgp** – Load sharing applies only to EBGP paths. Load sharing is disabled for IBGP paths.
- **ibgp** – Load sharing applies only to IBGP paths. Load sharing is disabled for EBGP paths.
- **multi-as** – Load sharing is enabled for paths from different autonomous systems.

By default, load sharing applies to EBGP and IBGP paths, and does not apply to paths from different neighboring autonomous systems.

Specifying a list of networks to advertise

By default, the router sends BGP4 routes only for the networks you identify using the **network** command or that are redistributed into BGP4 from RIP or OSPF. You can specify up to 600 networks.

To specify a network to be advertised, use either of the following methods.

NOTE

The exact route must exist in the IP route table before the Layer 3 switch can create a local BGP route.

To configure the Layer 3 switch to advertise network 209.157.22.0/24, enter the following command.

```
Brocade(config-bgp-router)#network 209.157.22.0 255.255.255.0
```

Syntax: `network <ip-addr> <ip-mask> [nlri multicast | unicast | multicast unicast] [route-map <map-name>] | [weight <num>] | [backdoor]`

The `<ip-addr>` is the network number and the `<ip-mask>` specifies the network mask.

The `nlri multicast | unicast | multicast unicast` parameter specifies whether the neighbor is a multicast neighbor or a unicast neighbor. Optionally, you also can specify **unicast** if you want the Layer 3 switch to exchange unicast (BGP4) routes as well as multicast routes with the neighbor. The default is **unicast** only.

The `route-map <map-name>` parameter specifies the name of the route map you want to use to set or change BGP4 attributes for the network you are advertising. The route map must already be configured.

The `weight <num>` parameter specifies a weight to be added to routes to this network.

The `backdoor` parameter changes the administrative distance of the route to this network from the EBGp administrative distance (20 by default) to the Local BGP weight (200 by default), thus tagging the route as a backdoor route. Use this parameter when you want the router to prefer IGP routes such as RIP or OSPF routes over the EBGp route for the network.

Specifying a route map name when configuring BGP4 network information

You can specify a route map as one of the parameters when you configure a BGP4 network to be advertised. The Layer 3 switch can use the route map to set or change BGP4 attributes when creating a local BGP4 route.

To configure network information and use a route map to set or change BGP4 attributes, use the following CLI method.

NOTE

You must configure the route map before you can specify the route map name in a BGP4 network configuration.

To configure a route map, and use it to set or change route attributes for a network you define for BGP4 to advertise, enter commands such as the following.

```
Brocade(config)#route-map set_net permit 1
Brocade(config-routemap set_net)#set community no-export
Brocade(config-routemap set_net)#exit
Brocade(config)#router bgp
Brocade(config-bgp-router)#network 100.100.1.0/24 route-map set_net
```

The first two commands in this example create a route map named “set_net” that sets the community attribute for routes that use the route map to “NO_EXPORT”. The next two commands change the CLI to the BGP4 configuration level. The last command configures a network for advertising from BGP4, and associates the “set_net” route map with the network. When BGP4 originates the 100.100.1.0/24 network, BGP4 also sets the community attribute for the network to “NO_EXPORT”.

Syntax: `network <ip-addr> <ip-mask> [route-map <map-name>] | [weight <num>] | [backdoor]`

The **route-map** *<map-name>* parameter specifies the name of the route map you want to use to set or change BGP4 attributes for the network you are advertising. The route map must already be configured.

For information about the other parameters, refer to [“Defining route maps”](#) on page 1403.

Changing the default local preference

When the router uses the BGP4 algorithm to select a route to send to the IP route table, one of the parameters the algorithm uses is the local preference. Local preference is an attribute that indicates a degree of preference for a route relative to other routes. BGP4 neighbors can send the local preference value as an attribute of a route in an UPDATE message.

Local preference applies only to routes within the local AS. BGP4 routers can exchange local preference information with neighbors who also are in the local AS, but BGP4 routers do not exchange local preference information with neighbors in remote autonomous systems.

The default local preference is 100. For routes learned from EBGp neighbors, the default local preference is assigned to learned routes. For routes learned from IBGP neighbors, the local preference value is not changed for the route.

When the BGP4 algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen.

NOTE

To set the local preference for individual routes, use route maps. Refer to [“Defining route maps”](#) on page 1403. Refer to [“How BGP4 selects a path for a route”](#) on page 1344 for information about the BGP4 algorithm.

To change the default local preference to 200, enter the following command.

```
Brocade(config-bgp-router)#default-local-preference 200
```

Syntax: **default-local-preference** *<num>*

The *<num>* parameter indicates the preference and can be a value from 0 through 4294967295.

Using the IP default route as a valid next hop for a BGP4 route

By default, the Layer 3 switch does not use a default route to resolve a BGP4 next-hop route. If the IP route lookup for the BGP4 next hop does not result in a valid IGP route (including static or direct routes), the BGP4 next hop is considered to be unreachable and the BGP4 route is not used.

In some cases, such as when the Layer 3 switch is acting as an edge router, you might want to allow the device to use the default route as a valid next hop. To do so, enter the following command at the BGP4 configuration level of the CLI.

```
Brocade(config-bgp-router)#next-hop-enable-default
```

Syntax: **[no] next-hop-enable-default**

Advertising the default route

By default, the Layer 3 switch does not originate and advertise a default route using BGP4. A BGP4 default route is the IP address 0.0.0.0 and the route prefix 0 or network mask 0.0.0.0. For example, 0.0.0.0/0 is a default route. You can enable the router to advertise a default BGP4 route using either of the following methods.

NOTE

The Brocade Layer 3 switch checks for the existence of an IGP route for 0.0.0.0/0 in the IP route table before creating a local BGP route for 0.0.0.0/0.

To enable the router to originate and advertise a default BGP4 route, enter the following command.

```
Brocade(config-bgp-router)#default-information-originate
```

Syntax: [no] default-information-originate

Changing the default MED (Metric) used for route redistribution

The Brocade Layer 3 switch can redistribute directly connected routes, static IP routes, RIP routes, and OSPF routes into BGP4. The MED (metric) is a global parameter that specifies the cost that will be applied to all routes by default when they are redistributed into BGP4. When routes are selected, lower metric values are preferred over higher metric values. The default BGP4 MED value is 0 and can be assigned a value from 0 through 4294967295.

NOTE

RIP and OSPF also have default metric parameters. The parameters are set independently for each protocol and have different ranges.

To change the default metric to 40, enter the following command.

```
Brocade(config-bgp-router)#default-metric 40
```

Syntax: default-metric <num>

The <num> indicates the metric and can be a value from 0 through 4294967295.

Enabling next-hop recursion

For each BGP4 route a Layer 3 switch learns, the Layer 3 switch performs a route lookup to obtain the IP address of the route next hop. A BGP4 route becomes eligible for installation into the IP route table only if the following conditions are true:

- The lookup succeeds in obtaining a valid next-hop IP address for the route.
- The path to the next-hop IP address is an Interior Gateway Protocol (IGP) path or a static route path.

By default, the software performs only one lookup for a BGP route next-hop IP address. If the next-hop lookup does not result in a valid next-hop IP address or the path to the next-hop IP address is a BGP path, the software considers the BGP route destination to be unreachable. The route is not eligible to be installed in the IP route table.

It is possible for the BGP route table to contain a route whose next-hop IP address is not reachable through an IGP route, even though a hop farther away can be reached by the Layer 3 switch through an IGP route. This can occur when the IGP does not learn a complete set of IGP routes, resulting in the Layer 3 switch learning about an internal route through IBGP instead of through an IGP. In this case, the IP route table does not contain a route that can be used to reach the BGP route destination.

To enable the Layer 3 switch to find the IGP route to a BGP route next-hop gateway, enable recursive next-hop lookups. When you enable recursive next-hop lookup, if the first lookup for a BGP route results in an IBGP path originated within the same Autonomous System (AS), rather than an IGP path or static route path, the Layer 3 switch performs a lookup on the next-hop gateway next-hop IP address. If this second lookup results in an IGP path, the software considers the BGP route to be valid and thus eligible for installation in the IP route table. Otherwise, the Layer 3 switch performs a lookup on the next-hop IP address of the next-hop gateway next hop, and so on, until one of the lookups results in an IGP route.

NOTE

The software does not support using the default route to resolve a BGP4 route's next hop. Instead, you must configure a static route or use an IGP to learn the route to the EBGP multihop peer.

Previous software releases support use of the default route to resolve routes learned from EBGP multihop neighbors. However, even in this case Brocade recommends that you use a static route for the EBGP multihop neighbor instead. In general, we recommend that you do not use the default route as the next hop for BGP4 routes, especially when there are two or more BGP4 neighbors. Using the default route can cause loops.

Example when recursive route lookups are disabled

Here is an example of the results of an unsuccessful next-hop lookup for a BGP route. In this case, next-hop recursive lookups are disabled. The example is for the BGP route to network 240.0.0.0/24.

```
Brocade#show ip bgp route
Total number of BGP Routes: 5
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
       H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED
       Prefix      Next Hop      Metric      LocPrf      Weight      Status
1       0.0.0.0/0    10.1.0.2      0           100         0          BI
       AS_PATH: 65001 4355 701 80
2       102.0.0.0/24 10.0.0.1      1           100         0          BI
       AS_PATH: 65001 4355 1
3       104.0.0.0/24 10.1.0.2      0           100         0          BI
       AS_PATH: 65001 4355 701 1 189
4       240.0.0.0/24 102.0.0.1    1          100        0          I
       AS_PATH: 65001 4355 3356 7170 1455
5       250.0.0.0/24 209.157.24.1  1           100         0          I
       AS_PATH: 65001 4355 701
```

In this example, the Layer 3 switch cannot reach 240.0.0.0/24, because the next-hop IP address for the route is an IBGP route instead of an IGP route, and thus is considered unreachable by the Layer 3 switch. Here is the IP route table entry for the BGP route next-hop gateway (102.0.0.1/24).

```

Brocade#show ip route 102.0.0.1
Total number of IP routes: 37

```

Network Address	NetMask	Gateway	Port	Cost	Type
102.0.0.0	255.255.255.0	10.0.0.1	1/1	1	B

The route to the next-hop gateway is a BGP route, not an IGP route, and thus cannot be used to reach 240.0.0.0/24. In this case, the Layer 3 switch tries to use the default route, if present, to reach the subnet that contains the BGP route next-hop gateway.

```

Brocade#show ip route 240.0.0.0/24
Total number of IP routes: 37

```

Network Address	NetMask	Gateway	Port	Cost	Type
0.0.0.0	0.0.0.0	10.0.0.202	1/1	1	S

Example when recursive route lookups are enabled

When recursive next-hop lookups are enabled, the Layer 3 switch recursively looks up the next-hop gateways along the route until the Layer 3 switch finds an IGP route to the BGP route destination. Here is an example.

```

Brocade#show ip bgp route
Total number of BGP Routes: 5
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED

```

	Prefix	Next Hop	Metric	LocPrf	Weight	Status
1	0.0.0.0/0	10.1.0.2	0	100	0	BI
	AS_PATH: 65001 4355 701 80					
2	102.0.0.0/24	10.0.0.1	1	100	0	BI
	AS_PATH: 65001 4355 1					
3	104.0.0.0/24	10.1.0.2	0	100	0	BI
	AS_PATH: 65001 4355 701 1 189					
4	240.0.0.0/24	102.0.0.1	1	100	0	BI
	AS_PATH: 65001 4355 3356 7170 1455					
5	250.0.0.0/24	209.157.24.1	1	100	0	I
	AS_PATH: 65001 4355 701					

The first lookup results in an IBGP route, to network 102.0.0.0/24.

```

Brocade#show ip route 102.0.0.1
Total number of IP routes: 38

```

Network Address	NetMask	Gateway	Port	Cost	Type
102.0.0.0	255.255.255.0	10.0.0.1	1/1	1	B
AS_PATH: 65001 4355 1					

Since the route to 102.0.0.1/24 is not an IGP route, the Layer 3 switch cannot reach the next hop through IP, and thus cannot use the BGP route. In this case, since recursive next-hop lookups are enabled, the Layer 3 switch next performs a lookup for 102.0.0.1 next-hop gateway, 10.0.0.1.

Optional BGP4 configuration tasks

```
Brocade#show ip bgp route 102.0.0.0
Number of BGP Routes matching display condition : 1
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED
Prefix          Next Hop          Metric      LocPrf      Weight Status
1      102.0.0.0/24    10.0.0.1      1           100         0      BI
      AS_PATH: 65001 4355 1
```

The next-hop IP address for 102.0.0.1 is not an IGP route, which means the BGP route destination still cannot be reached through IP. The recursive next-hop lookup feature performs a lookup on 10.0.0.1 next-hop gateway.

```
Brocade#show ip route 10.0.0.1
Total number of IP routes: 38
Network Address    NetMask          Gateway          Port      Cost      Type
10.0.0.0           255.255.255.0    0.0.0.0          1/1       1         D
      AS_PATH: 65001 4355 1
```

This lookup results in an IGP route. In fact, this route is a directly-connected route. As a result, the BGP route destination is now reachable through IGP, which means the BGP route is eligible for installation in the IP route table. Here is the BGP route in the IP route table.

```
Brocade#show ip route 240.0.0.0/24
Total number of IP routes: 38
Network Address    NetMask          Gateway          Port      Cost      Type
240.0.0.0          255.255.255.0    10.0.0.1         1/1       1         B
      AS_PATH: 65001 4355 1
```

This Layer 3 switch can use this route because the Layer 3 switch has an IP route to the next-hop gateway. Without recursive next-hop lookups, this route would not be in the IP route table.

Enabling recursive next-hop lookups

The recursive next-hop lookups feature is disabled by default. To enable recursive next-hop lookups, enter the **next-hop-recursion** command at the BGP configuration level of the CLI.

```
Brocade(config-bgp-router)#next-hop-recursion
```

Syntax: [no] next-hop-recursion

Changing administrative distances

BGP4 routers can learn about networks from various protocols, including the EBGP portion of BGP4 and IGP's such as OSPF and RIP. Consequently, the routes to a network may differ depending on the protocol from which the routes were learned.

To select one route over another based on the source of the route information, the Layer 3 switch can use the administrative distances assigned to the sources. The administrative distance is a protocol-independent metric that IP routers use to compare routes from different sources.

The Layer 3 switch re-advertises a learned best BGP4 route to the Layer 3 switch neighbors even when the software does not also select that route for installation in the IP route table. The best BGP4 routes is the BGP4 path that the software selects based on comparison of the paths' BGP4 route parameters. Refer to [“How BGP4 selects a path for a route”](#) on page 1344.

When selecting a route from among different sources (BGP4, OSPF, RIP, static routes, and so on), the software compares the routes on the basis of each route administrative distance. If the administrative distance of the paths is lower than the administrative distance of paths from other sources (such as static IP routes, RIP, or OSPF), the BGP4 paths are installed in the IP route table.

NOTE

The software will replace a statically configured default route with a learned default route if the learned route administrative distance is lower than the statically configured default route distance. However, the default administrative distance for static routes is changed to 1, so only directly-connected routes are preferred over static routes when the default administrative distances for the routes are used.

The following default administrative distances are found on the Brocade Layer 3 switch:

- Directly connected – 0 (this value is not configurable)
- Static – 1 (applies to all static routes, including default routes)
- EBGp – 20
- OSPF – 110
- RIP – 120
- IBGP – 200
- Local BGP – 200
- Unknown – 255 (the router will not use this route)

Lower administrative distances are preferred over higher distances. For example, if the router receives routes for the same network from OSPF and from RIP, the router will prefer the OSPF route by default. The administrative distances are configured in different places in the software. The Layer 3 switch re-advertises a learned best BGP4 route to neighbors by default, regardless of whether the route administrative distance is lower than other routes from different route sources to the same destination.

- To change the EBGp, IBGP, and Local BGP default administrative distances, see the instructions in this section.
- To change the default administrative distance for OSPF, refer to [“Administrative distance”](#) on page 1265.
- To change the default administrative distance for RIP, refer to [“Changing the administrative distance”](#) on page 1204.
- To change the default administrative distance for static routes, refer to [“Static routes configuration”](#) on page 991.

You can change the default EBGp, IBGP, and Local BGP administrative distances using either of the following methods.

To change the default administrative distances for EBGp, IBGP, and Local BGP, enter a command such as the following.

```
Brocade(config-bgp-router)#distance 180 160 40
```

Syntax: **distance** <external-distance> <internal-distance> <local-distance>

The <external-distance> sets the EBGp distance and can be a value from 1 through 255.

The <internal-distance> sets the IBGP distance and can be a value from 1 through 255.

The <local-distance> sets the Local BGP distance and can be a value from 1 through 255.

Requiring the first AS to be the neighbor AS

By default, the Brocade device does not require the first AS listed in the AS_SEQUENCE field of an AS path Update from an EBGP neighbor to be the AS that the neighbor who sent the Update is in. You can enable the Brocade device for this requirement.

When you enable the Brocade device to require the AS that an EBGP neighbor is in to be the same as the first AS in the AS_SEQUENCE field of an Update from the neighbor, the Brocade device accepts the Update only if the autonomous systems match. If the autonomous systems do not match, the Brocade device sends a Notification message to the neighbor and closes the session. The requirement applies to all Updates received from EBGP neighbors.

To enable this feature, enter the following command at the BGP configuration level of the CLI.

```
Brocade(config-bgp-router)#enforce-first-as
```

Syntax: [no] enforce-first-as

Disabling or re-enabling comparison of the AS-Path length

AS-Path comparison is Step 5 in the algorithm BGP4 uses to select the next path for a route. Comparison of the AS-Path length is enabled by default. To disable it, enter the following command at the BGP configuration level of the CLI.

```
Brocade(config-bgp-router)#as-path-ignore
```

This command disables comparison of the AS-Path lengths of otherwise equal paths. When you disable AS-Path length comparison, the BGP4 algorithm shown in [“How BGP4 selects a path for a route”](#) on page 1344 skips from Step 4 to Step 6.

Syntax: [no] as-path-ignore

Enabling or disabling comparison of the router IDs

Router ID comparison is Step 10 in the algorithm BGP4 uses to select the next path for a route.

NOTE

Comparison of router IDs is applicable only when BGP4 load sharing is disabled.

When router ID comparison is enabled, the path comparison algorithm compares the router IDs of the neighbors that sent the otherwise equal paths:

- If BGP4 load sharing is disabled (maximum-paths 1), the Layer 3 switch selects the path that came from the neighbor with the lower router ID.
- If BGP4 load sharing is enabled, the Layer 3 switch load shares among the remaining paths. In this case, the router ID is not used to select a path.

NOTE

Router ID comparison is disabled by default. In previous releases, router ID comparison is enabled by default and cannot be disabled.

To enable router ID comparison, enter the **compare-routerid** command at the BGP configuration level of the CLI.

```
Brocade(config-bgp-router)#compare-routerid
```

Syntax: [no] compare-routerid

For more information, refer to [“How BGP4 selects a path for a route”](#) on page 1344.

Configuring the Layer 3 switch to always compare Multi-Exit Discriminators (MEDs)

A Multi-Exit Discriminator (MED) is a value that the BGP4 algorithm uses when comparing multiple paths received from different BGP4 neighbors in the same AS for the same route. In BGP4, a route MED is equivalent to its “metric”:

- BGP4 compares the MEDs of two otherwise equivalent paths **if and only if** the routes were learned from the same neighboring AS. This behavior is called **deterministic MED**. Deterministic MED is always enabled and cannot be disabled.

In addition, you can enable the Layer 3 switch to always compare the MEDs, regardless of the AS information in the paths. To enable this comparison, enter the **always-compare-med** command at the BGP4 configuration level of the CLI. This option is disabled by default.

- The Layer 3 switch compares the MEDs based on one or more of the following conditions. By default, the Layer 3 switch compares the MEDs of paths **only if** the first AS in the paths is the same. (The Layer 3 switch skips over the AS-CONFED-SEQUENCE if present.)

You can enable the Layer 3 switch to always compare the MEDs, regardless of the AS information in the paths. For example, if the router receives UPDATES for the same route from neighbors in three autonomous systems, the router would compare the MEDs of all the paths together, rather than comparing the MEDs for the paths in each AS individually.

NOTE

By default, value 0 (most favorable) is used in MED comparison when the MED attribute is not present. The default MED comparison results in the Layer 3 switch favoring the route paths that are missing their MEDs. You can use the **med-missing-as-worst** command to make the Layer 3 switch regard a BGP route with a missing MED attribute as the least favorable route, when comparing the MEDs of the routes.

NOTE

MED comparison is not performed for internal routes originated within the local AS or confederation.

To configure the router to always compare MEDs, enter the following command.

```
Brocade(config-bgp-router)#always-compare-med
```

Syntax: [no] always-compare-med

Treating missing MEDs as the worst MEDs

By default, the Layer 3 switch favors a lower MED over a higher MED during MED comparison. Since the Layer 3 switch assigns the value 0 to a route path MED if the MED value is missing, the default MED comparison results in the Layer 3 switch favoring the route paths that are missing their MEDs.

To change this behavior so that the Layer 3 switch favors a route that has a MED over a route that is missing its MED, enter the following command at the BGP4 configuration level of the CLI.

```
Brocade(config-bgp-router)#med-missing-as-worst
```

Syntax: [no] med-missing-as-worst

NOTE

This command affects route selection only when route paths are selected based on MED comparison. It is still possible for a route path that is missing its MED to be selected based on other criteria. For example, a route path with no MED can be selected if its weight is larger than the weights of the other route paths.

Route reflection parameter configuration

Normally, all the BGP routers within an AS are fully meshed. Each of the routers has an IBGP session with each of the other BGP routers in the AS. Each IBGP router thus has a route for each of its IBGP neighbors. For large autonomous systems containing many IBGP routers, the IBGP route information in each of the fully-meshed IBGP routers can introduce too much administrative overhead.

To avoid this problem, you can hierarchically organize your IGP routers into clusters:

- A **cluster** is a group of IGP routers organized into route reflectors and route reflector clients. You configure the cluster by assigning a cluster ID on the route reflector and identifying the IGP neighbors that are members of that cluster. All the configuration for route reflection takes place on the route reflectors. The clients are unaware that they are members of a route reflection cluster. All members of the cluster must be in the same AS. The cluster ID can be any number from 0 through 4294967295. The default is the router ID, expressed as a 32-bit number.

NOTE

If the cluster contains more than one route reflector, you need to configure the same cluster ID on all the route reflectors in the cluster. The cluster ID helps route reflectors avoid loops within the cluster.

- A **route reflector** is an IGP router configured to send BGP route information to all the clients (other BGP4 routers) within the cluster. Route reflection is enabled on all Brocade BGP4 routers by default but does not take effect unless you add route reflector clients to the router.
- A **route reflector client** is an IGP router identified as a member of a cluster. You identify a router as a route reflector client on the router that is the route reflector, not on the client. The client itself requires no additional configuration. In fact, the client does not know that it is a route reflector client. The client just knows that it receives updates from its neighbors and does not know whether one or more of those neighbors are route reflectors.

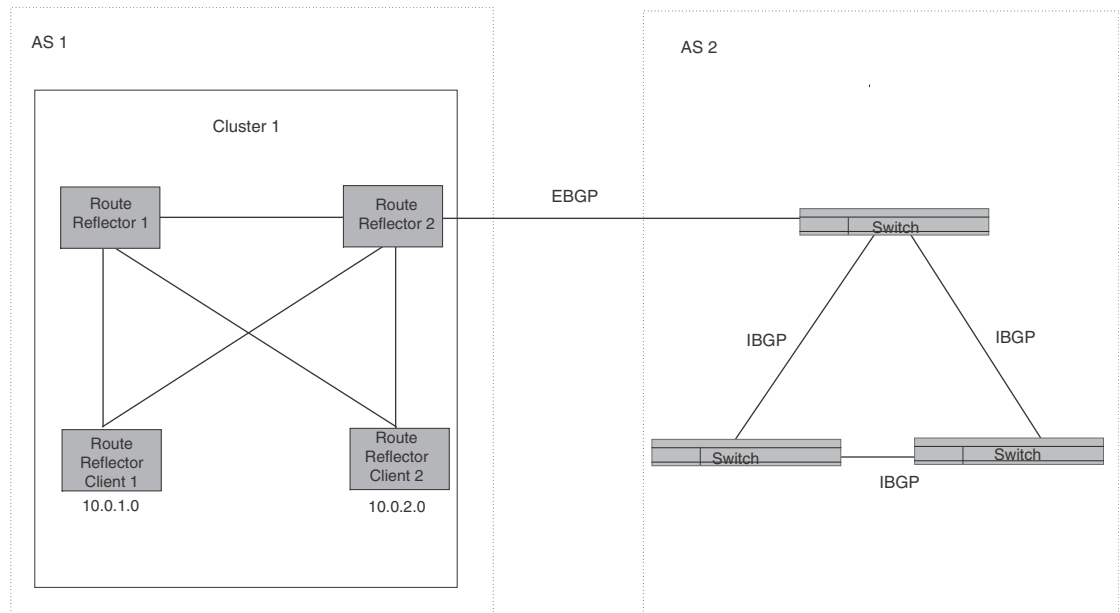

NOTE

Route reflection applies only among IBGP routers within the same AS. You cannot configure a cluster that spans multiple autonomous systems.

Figure 167 shows an example of a route reflector configuration. In this example, two Layer 3 switches are configured as route reflectors for the same cluster. The route reflectors provide redundancy in case one of the reflectors becomes unavailable. Without redundancy, if a route reflector becomes unavailable, its clients are cut off from BGP4 updates.

AS1 contains a cluster with two route reflectors and two clients. The route reflectors are fully meshed with other BGP4 routers, but the clients are not fully meshed. They rely on the route reflectors to propagate BGP4 route updates.

FIGURE 167 Example of a route reflector configuration

Route reflection based on RFC 2796

Route reflection on Brocade devices is based on RFC 2796. This updated RFC helps eliminate routing loops that are possible in some implementations of the older specification, RFC 1966.

NOTE

The configuration procedure for route reflection is the same regardless of whether your software release is using RFC 1966 or RFC 2796. However, the operation of the feature is different as explained below.

RFC 2796 provides more details than RFC 1966 regarding the use of the route reflection attributes, `ORIGINATOR_ID` and `CLUSTER_LIST`, to help prevent loops:

- **ORIGINATOR_ID** – Specifies the router ID of the BGP4 switch that originated the route. The route reflector inserts this attribute when reflecting a route to an IBGP neighbor. If a BGP4 switch receives an advertisement that contains its own router ID as the `ORIGINATOR_ID`, the switch discards the advertisement and does not forward it.
- **CLUSTER_LIST** – A list of the route reflection clusters through which the advertisement has passed. A cluster contains a route reflector and its clients. When a route reflector reflects a route, the route reflector adds its cluster ID to the front of the `CLUSTER_LIST`. If a route reflector receives a route that has its own cluster ID, the switch discards the advertisement and does not forward it.

The Brocade device handles the attributes as follows:

- The Layer 3 switch adds the attributes only if it is a route reflector, and only when advertising IBGP route information to other IBGP neighbors. The attributes are not used when communicating with EBGP neighbors.
- A Layer 3 switch configured as a route reflector sets the ORIGINATOR_ID attribute to the router ID of the router that originated the route. Moreover, the route reflector sets the attribute only if this is the first time the route is being reflected (sent by a route reflector). In previous software releases, the route reflector set the attribute to the router ID of the route reflector itself. When a Layer 3 switch receives a route that already has the ORIGINATOR_ID attribute set, the Layer 3 switch does not change the value of the attribute.
- If a Layer 3 switch receives a route whose ORIGINATOR_ID attribute has the value of the Layer 3 switch own router ID, the Layer 3 switch discards the route and does not advertise it. By discarding the route, the Layer 3 switch prevents a routing loop. The Layer 3 switch did not discard the route in previous software releases.
- The first time a route is reflected by a Layer 3 switch configured as a route reflector, the route reflector adds the CLUSTER_LIST attribute to the route. Other route reflectors who receive the route from an IBGP neighbor add their cluster IDs to the front of the route CLUSTER_LIST. If the route reflector does not have a cluster ID configured, the Layer 3 switch adds its router ID to the front of the CLUSTER_LIST.
- If a Layer 3 switch configured as a route reflector receives a route whose CLUSTER_LIST contains the route reflector own cluster ID, the route reflector discards the route and does not forward it.

Configuration procedures for BGP4 route reflector

To configure a Brocade Layer 3 switch to be a BGP4 route reflector, use either of the following methods.

NOTE

All configuration for route reflection takes place on the route reflectors, not on the clients.

Enter the following commands to configure a Brocade Layer 3 switch as route reflector 1 in [Figure 167](#) on page 1379. To configure route reflector 2, enter the same commands on the Layer 3 switch that will be route reflector 2. The clients require no configuration for route reflection.

```
Brocade(config-bgp-router)#cluster-id 1
Brocade(config-bgp-router)#neighbor 10.0.1.0 route-reflector-client
Brocade(config-bgp-router)#neighbor 10.0.2.0 route-reflector-client
```

Syntax: [no] cluster-id <num> | <ip-addr>

The <num> | <ip-addr> parameter specifies the cluster ID and can be a number from 0 through 4294967295 or an IP address. The default is the router ID. You can configure one cluster ID on the router. All route-reflector clients for the router are members of the cluster.

NOTE

If the cluster contains more than one route reflector, you need to configure the same cluster ID on all the route reflectors in the cluster. The cluster ID helps route reflectors avoid loops within the cluster.

To add an IBGP neighbor to the cluster, enter the following command.

Syntax: neighbor <ip-addr> route-reflector-client

For more information about the **neighbor** command, refer to [“Adding BGP4 neighbors”](#) on page 1354.

By default, the clients of a route reflector are not required to be fully meshed; the routes from a client are reflected to other clients. However, if the clients are fully meshed, route reflection is not required between clients.

If you need to disable route reflection between clients, enter the following command. When the feature is disabled, route reflection does not occur between clients but reflection does still occur between clients and non-clients.

```
Brocade(config-bgp-router)#no client-to-client-reflection
```

Enter the following command to re-enable the feature.

```
Brocade(config-bgp-router)#client-to-client-reflection
```

Syntax: [no] client-to-client-reflection

Configuration notes for BGP4 autonomous systems

A **confederation** is a BGP4 Autonomous System (AS) that has been subdivided into multiple, smaller autonomous systems. Subdividing an AS into smaller autonomous systems simplifies administration and reduces BGP-related traffic, thus reducing the complexity of the Interior Border Gateway Protocol (IBGP) mesh among the BGP routers in the AS.

The Brocade implementation of this feature is based on RFC 3065.

Normally, all BGP routers within an AS must be fully meshed, so that each BGP router has interfaces to all the other BGP routers within the AS. This is feasible in smaller autonomous systems but becomes unmanageable in autonomous systems containing many BGP routers.

When you configure BGP routers into a confederation, all the routers within a sub-AS (a subdivision of the AS) use IBGP and must be fully meshed. However, routers use EBGP to communicate between different sub-autonomous systems.

NOTE

Another method for reducing the complexity of an IBGP mesh is to use route reflection. However, if you want to run different Interior Gateway Protocols (IGPs) within an AS, configure a confederation. You can run a separate IGP within each sub-AS.

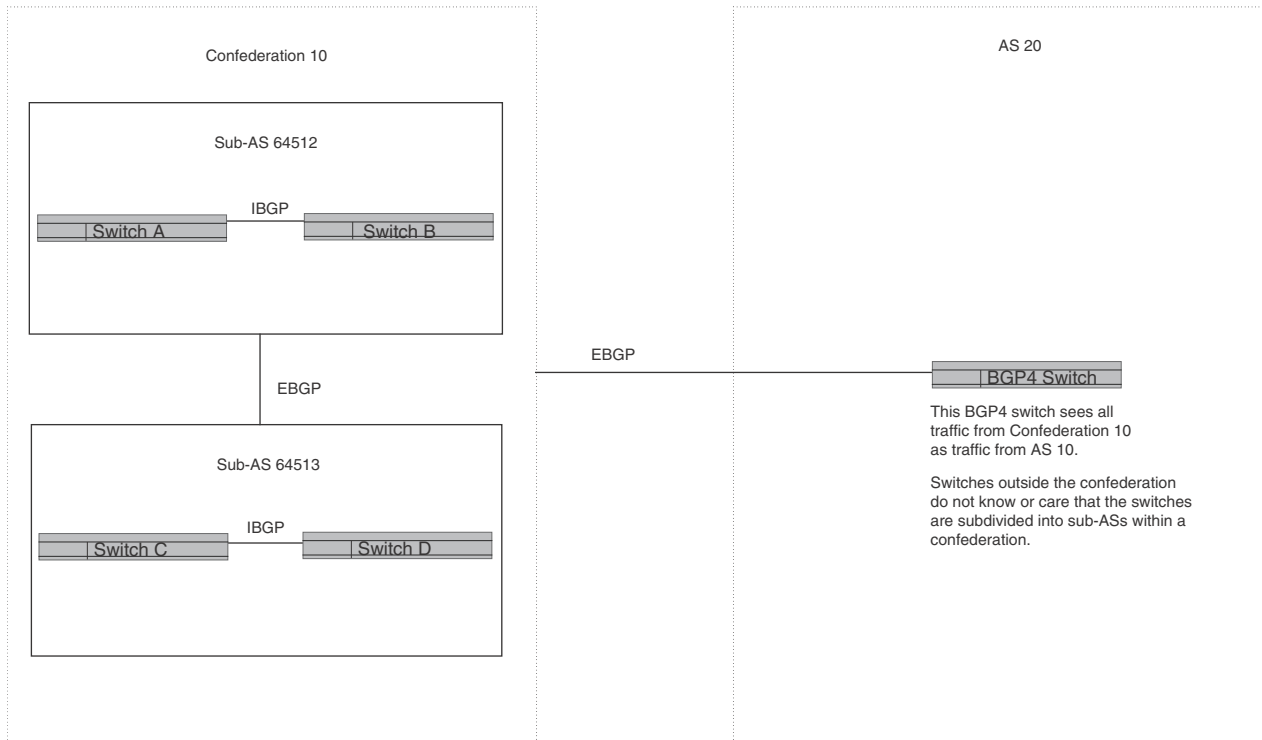

To configure a confederation, configure groups of BGP routers into sub-autonomous systems. A sub-AS is simply an AS. The term “sub-AS” distinguishes autonomous systems within a confederation from autonomous systems that are not in a confederation. For the viewpoint of remote autonomous systems, the confederation ID is the AS ID. Remote autonomous systems do not know that the AS represents multiple sub-autonomous systems with unique AS IDs.

NOTE

You can use any valid AS numbers for the sub-autonomous systems. If your AS is connected to the Internet, Brocade recommends that you use numbers from within the private AS range (64512 through 65535). These are private autonomous systems numbers and BGP4 routers do not propagate these AS numbers to the Internet.

Figure 168 shows an example of a BGP4 confederation.

FIGURE 168 Example of a BGP4 confederation

In this example, four switches are configured into two sub-autonomous systems, each containing two of the switches. The sub-autonomous systems are members of confederation 10. Switches within a sub-AS must be fully meshed and communicate using IBGP. In this example, Switches A and B use IBGP to communicate. Switches C and D also use IBGP. However, the sub-autonomous systems communicate with one another using EBGP. For example, Switch A communicates with Switch C using EBGP. The switches in the confederation communicate with other autonomous systems using EBGP.

Switches in other autonomous systems are unaware that Switches A through D are configured in a confederation. In fact, when switches in confederation 10 send traffic to switches in other autonomous systems, the confederation ID is the same as the AS number for the switches in the confederation. Thus, switches in other autonomous systems see traffic from AS 10 and are unaware that the switches in AS 10 are subdivided into sub-autonomous systems within a confederation.

Configuring a BGP confederation

Perform the following configuration tasks on each BGP router within the confederation:

- Configure the local AS number. The local AS number indicates membership in a sub-AS. All BGP switches with the same local AS number are members of the same sub-AS. BGP switches use the local AS number when communicating with other BGP switches within the confederation.

- Configure the confederation ID. The confederation ID is the AS number by which BGP switches outside the confederation know the confederation. Thus, a BGP switch outside the confederation is not aware and does not care that your BGP switches are in multiple sub-autonomous systems. BGP switches use the confederation ID when communicating with switches outside the confederation. The confederation ID must be different from the sub-AS numbers.
- Configure the list of the sub-AS numbers that are members of the confederation. All the switches within the same sub-AS use IBGP to exchange switch information. Switches in different sub-autonomous systems within the confederation use EBGP to exchange switch information.

To configure four Layer 3 switches to be a member of confederation 10 (as shown in [Figure 168](#)), consisting of two sub-autonomous systems (64512 and 64513), enter commands such as the following.

Commands for router A

```
BrocadeA(config)#router bgp
BrocadeA(config-bgp-router)#local-as 64512
BrocadeA(config-bgp-router)#confederation identifier 10
BrocadeA(config-bgp-router)#confederation peers 64512 64513
BrocadeA(config-bgp-router)#write memory
```

Syntax: local-as <num>

The <num> parameter with the **local-as** command indicates the AS number for the BGP switches within the sub-AS. You can specify a number from 1 through 65535. Brocade recommends that you use a number within the range of well-known private autonomous systems, 64512 through 65535.

Syntax: confederation identifier <num>

The <num> parameter with the **confederation identifier** command indicates the confederation number. The confederation ID is the AS number by which BGP switches outside the confederation know the confederation. Thus, a BGP switch outside the confederation is not aware and does not care that your BGP switches are in multiple sub-autonomous systems. BGP switches use the confederation ID when communicating with switches outside the confederation. The confederation ID must be different from the sub-AS numbers. You can specify a number from 1 through 65535.

Syntax: confederation peers <num> [<num> ...]

The <num> parameter with the **confederation peers** command indicates the sub-AS numbers for the sub-autonomous systems in the confederation. You must specify all the sub-autonomous systems contained in the confederation. All the switches within the same sub-AS use IBGP to exchange switch information. Switches in different sub-autonomous systems within the confederation use EBGP to exchange switch information. You can specify a number from 1 through 65535.

Commands for router B

```
BrocadeB(config)#router bgp
BrocadeB(config-bgp-router)#local-as 64512
BrocadeB(config-bgp-router)#confederation identifier 10
BrocadeB(config-bgp-router)#confederation peers 64512 64513
BrocadeB(config-bgp-router)#write memory
```

Commands for router C

```
BrocadeC(config)#router bgp
BrocadeC(config-bgp-router)#local-as 64513
BrocadeC(config-bgp-router)#confederation identifier 10
BrocadeC(config-bgp-router)#confederation peers 64512 64513
BrocadeC(config-bgp-router)#write memory
```

Commands for router D

```
BrocadeD(config)#router bgp
BrocadeD(config-bgp-router)#local-as 64513
BrocadeD(config-bgp-router)#confederation identifier 10
BrocadeD(config-bgp-router)#confederation peers 64512 64513
BrocadeD(config-bgp-router)#write memory
```

Aggregating routes advertised to BGP4 neighbors

By default, the Layer 3 switch advertises individual routes for all the networks. The aggregation feature allows you to configure the Layer 3 switch to aggregate routes in a range of networks into a single CIDR number. For example, without aggregation, the Layer 3 switch will individually advertise routes for networks 207.95.1.0, 207.95.2.0, and 207.95.3.0. You can configure the Layer 3 switch to instead send a single, aggregate route for the networks. The aggregate route would be advertised as 207.95.0.0.

NOTE

To summarize CIDR networks, you must use the aggregation feature. The auto summary feature does not summarize networks that use CIDR numbers instead of class A, B, or C numbers.

To aggregate routes for 209.157.22.0, 209.157.23.0, and 209.157.24.0, enter the following command.

```
Brocade(config-bgp-router)#aggregate-address 209.157.0.0 255.255.0.0
```

Syntax: `aggregate-address <ip-addr> <ip-mask> [as-set] [nlri multicast | unicast | multicast unicast] [summary-only] [suppress-map <map-name>] [advertise-map <map-name>] [attribute-map <map-name>]`

The `<ip-addr>` and `<ip-mask>` parameters specify the aggregate value for the networks. Specify 0 for the host portion and for the network portion that differs among the networks in the aggregate. For example, to aggregate 10.0.1.0, 10.0.2.0, and 10.0.3.0, enter the IP address 10.0.0.0 and the network mask 255.255.0.0.

The `as-set` parameter causes the router to aggregate AS-path information for all the routes in the aggregate address into a single AS-path.

The `nlri multicast | unicast | multicast unicast` parameter specifies whether the neighbor is a multicast neighbor or a unicast neighbor. Optionally, you also can specify `unicast` if you want the Layer 3 switch to exchange unicast (BGP4) routes as well as multicast routes with the neighbor. The default is `unicast` only.

The `summary-only` parameter prevents the router from advertising more specific routes contained within the aggregate route.

The `suppress-map <map-name>` parameter prevents the more specific routes contained in the specified route map from being advertised.

The **advertise-map** <map-name> parameter configures the router to advertise the more specific routes in the specified route map.

The **attribute-map** <map-name> parameter configures the router to set attributes for the aggregate routes based on the specified route map.

NOTE

For the **suppress-map**, **advertise-map**, and **attribute-map** parameters, the route map must already be defined. Refer to [“Defining route maps”](#) on page 1403 for information on defining a route map.

Configuring BGP4 graceful restart

By default, BGP4 graceful restart is enabled for the global routing instance. This section describes how to disable and re-enable the BGP4 restart feature and change the default values for associated timers.

For information about displaying BGP4 graceful restart neighbor information, refer to [“Displaying BGP4 graceful restart neighbor information”](#) on page 1451.

Configuring BGP4 graceful restart

BGP4 graceful restart is enabled by default on a FastIron Layer 3 switch. To disable it, use the following commands:

```
Brocade(config)# router bgp
Brocade(config-bgp)# no graceful-restart
```

To re-enable BGP4 graceful restart after it has been disabled, enter the following commands.

```
Brocade(config)# router bgp
Brocade(config-bgp)# graceful-restart
```

Syntax: [no] graceful-restart

Configuring timers for BGP4 graceful restart (optional)

You can change the default values for the following timers:

- Restart timer
- Stale routes timer
- Purge timer

Configuring the restart timer for BGP4 graceful restart

Use the following command to specify the maximum amount of time a device will maintain routes from and forward traffic to a restarting device.

```
Brocade(config-bgp)# graceful-restart restart-timer 150
```

Syntax: [no] graceful-restart restart-timer <seconds>

The `<seconds>` variable is the maximum restart wait time advertised to neighbors. Possible values are from 1 through 3600 seconds. The default value is 120 seconds.

Configuring the BGP4 graceful restart stale routes timer

Use the following command to specify the maximum amount of time a helper device will wait for an end-of-RIB message from a peer before deleting routes from that peer.

```
Brocade(config-bgp)# graceful-restart stale-routes-time 120
```

Syntax: `[no] graceful-restart stale-routes-time <seconds>`

The `<seconds>` variable is the maximum time before a helper device cleans up stale routes. Possible values are from 1 through 3600 seconds. The default value is 360 seconds.

Configuring the BGP4 graceful restart purge timer

Use the following command to specify the maximum amount of time a device will maintain stale routes in its routing table before purging them.

```
Brocade(config-bgp)# graceful-restart purge-time 900
```

Syntax: `[no] graceful-restart purge-time <seconds>`

The `<seconds>` variable sets the maximum time before a restarting device cleans up stale routes. Possible values are from 1 through 3600 seconds. The default value is 600 seconds.

BGP null0 routing

The null0 routes were previously treated as invalid routes for BGP next hop resolution. BGP now uses the null0 route to resolve its next hop. Thus, null0 route in the routing table (for example, static route) is considered as a valid route by BGP. If the next hop for BGP resolves into a null0 route, the BGP route is also installed as a null0 route in the routing table.

The null0 routing feature allows network administrators to block certain network prefixes, by using null0 routes and route-maps. The combined use of null0 routes and route maps blocks traffic from a particular network prefix, telling a remote router to drop all traffic for this network prefix by redistributing a null0 route into BGP.

Figure 169 shows a topology for a null0 routing application example.

FIGURE 169 Example of a null0 routing application

The following steps configure a null0 routing application for stopping denial of service attacks from remote hosts on the internet.

Configuration steps for BGP null 0 routing

1. Select one switch, S6, to distribute null0 routes throughout the BGP network.
2. Configure a route-map to match a particular tag (50) and set the next-hop address to an unused network address (199.199.1.1).
3. Set the local-preference to a value higher than any possible internal or external local-preference (50).
4. Complete the route map by setting origin to IGP.
5. On S6, redistribute the static routes into BGP, using route-map <route-map-name> (redistribute static route-map block user).
6. On S1, the router facing the internet, configure a null0 route matching the next-hop address in the route-map (ip route 199.199.1.1/32 null0).
7. Repeat step 3 for all switches interfacing with the internet (edge corporate routers). In this case, S2 has the same null0 route as S1.
8. On S6, configure the network prefixes associated with the traffic you want to drop. The static route IP address references a destination address. You are required to point the static route to the egress port, for example, Ethernet 3/7, and specify the tag 50, matching the route-map configuration.

Configuration examples for BGP null 0 routing

S6

The following configuration defines specific prefixes to filter.

```
Brocade(config)#ip route 110.0.0.40/29 ethernet 3/7 tag 50
Brocade(config)#ip route 115.0.0.192/27 ethernet 3/7 tag 50
Brocade(config)#ip route 120.014.0/23 ethernet 3/7 tag 50
```

The following configuration redistributes routes into BGP.

```
Brocade(config)#router bgp
Brocade(config-bgp-router)#local-as 100
Brocade(config-bgp-router)#neighbor <router1_int_ip address> remote-as 100
Brocade(config-bgp-router)#neighbor <router2_int_ip address> remote-as 100
Brocade(config-bgp-router)#neighbor <router3_int_ip address> remote-as 100
Brocade(config-bgp-router)#neighbor <router4_int_ip address> remote-as 100
Brocade(config-bgp-router)#neighbor <router5_int_ip address> remote-as 100
Brocade(config-bgp-router)#neighbor <router7_int_ip address> remote-as 100
Brocade(config-bgp-router)#redistribute static route-map blockuser
Brocade(config-bgp-router)#exit
```

The following configuration defines the specific next hop address and sets the local preference to preferred.

```
Brocade(config)#route-map blockuser permit 10
Brocade(config-routemap blockuser)#match tag 50
Brocade(config-routemap blockuser)#set ip next-hop 199.199.1.1
Brocade(config-routemap blockuser)#set local-preference 1000000
Brocade(config-routemap blockuser)#set origin igp
Brocade(config-routemap blockuser)#exit
```

S1

The following configuration defines the null0 route to the specific next hop address. The next hop address 199.199.1.1 points to the null0 route.

```
Brocade(config)#ip route 199.199.1.1/32 null0
Brocade(config)#router bgp
Brocade(config-bgp-router)#local-as 100
Brocade(config-bgp-router)#neighbor <router2_int_ip address> remote-as 100
Brocade(config-bgp-router)#neighbor <router3_int_ip address> remote-as 100
Brocade(config-bgp-router)#neighbor <router4_int_ip address> remote-as 100
Brocade(config-bgp-router)#neighbor <router5_int_ip address> remote-as 100
Brocade(config-bgp-router)#neighbor <router6_int_ip address> remote-as 100
Brocade(config-bgp-router)#neighbor <router7_int_ip address> remote-as 100
```

S2

The following configuration defines a null0 route to the specific next hop address. The next hop address 199.199.1.1 points to the null0 route, which gets blocked.

```
Brocade(config)#ip route 199.199.1.1/32 null0
Brocade(config)#router bgp
Brocade(config-bgp-router)#local-as 100
Brocade(config-bgp-router)#neighbor <router1_int_ip address> remote-as 100
Brocade(config-bgp-router)#neighbor <router3_int_ip address> remote-as 100
```

```

Brocade(config-bgp-router)#neighbor <router4_int_ip address> remote-as 100
Brocade (config-bgp-router)#neighbor <router5_int_ip address> remote-as 100
Brocade(config-bgp-router)#neighbor <router6_int_ip address> remote-as 100
Brocade(config-bgp-router)#neighbor <router7_int_ip address> remote-as 100

```

Show commands for BGP null 0 routing

After configuring the null0 application, you can display the output.

S6

The following is the **show ip route static** output for S6.

```

Brocade#show ip route static
Type Codes - B:BGP D:Connected S:Static R:RIP O:OSPF; Cost - Dist/Metric
      Destination      Gateway      Port      Cost      Type
1      110.0.0.40/29      DIRECT      eth 3/7      1/1      S
2      115.0.0.192/27      DIRECT      eth 3/7      1/1      S
3      120.0.14.0/23      DIRECT      eth 3/7      1/1      S

```

S1 and S2

The following is the **show ip route static** output for S1 and S2.

```

Brocade#show ip route static
Type Codes - B:BGP D:Connected S:Static R:RIP O:OSPF; Cost - Dist/Metric
      Destination      Gateway      Port      Cost      Type

Modifying redistribution parameters

By default, the Layer 3 Switch does not redistribute route information between BGP4 and the IP IGPs (RIP and OSPF). You can configure the switch to redistribute OSPF routes, RIP routes, directly connected routes, or static routes into BGP4 by using the following methods.

To enable redistribution of all OSPF routes and directly attached routes into BGP4, enter the following commands.

```
Brocade(config)#router bgp
Brocade(config-bgp-router)#redistribute ospf
Brocade(config-bgp-router)#redistribute connected
Brocade(config-bgp-router)#write memory
```

Syntax: [no] **redistribute connected** | **ospf** | **rip** | **static**

The **connected** parameter indicates that you are redistributing routes to directly attached devices into BGP.

The **ospf** parameter indicates that you are redistributing OSPF routes into BGP4.

NOTE

Entering **redistribute ospf** simply redistributes internal OSPF routes. If you want to redistribute external OSPF routes also, you must use the **redistribute ospf match external...** command. Refer to [“Redistributing OSPF external routes”](#) on page 1392.

The **rip** parameter indicates that you are redistributing RIP routes into BGP4.

The **static** parameter indicates that you are redistributing static routes into BGP.

Refer to the following sections for details on redistributing specific routes using the CLI:

- [“Redistributing connected routes”](#) on page 1391
- [“Redistributing RIP routes”](#) on page 1392
- [“Redistributing OSPF external routes”](#) on page 1392
- [“Redistributing static routes”](#) on page 1393

Redistributing connected routes

To configure BGP4 to redistribute directly connected routes, enter the following command.

```
Brocade(config-bgp-router)#redistribute connected
```

Syntax: **redistribute connected** [**metric** <num>] [**route-map** <map-name>]

The **connected** parameter indicates that you are redistributing routes to directly attached devices into BGP4.

The **metric** <num> parameter changes the metric. You can specify a value from 0 through 4294967295. The default is 0.

The **route-map** <map-name> parameter specifies a route map to be consulted before adding the RIP route to the BGP4 route table.

NOTE

The route map you specify must already be configured on the switch. Refer to [“Defining route maps”](#) on page 1403 for information about defining route maps.

Redistributing RIP routes

To configure BGP4 to redistribute RIP routes and add a metric of 10 to the redistributed routes, enter the following command.

```
Brocade(config-bgp-router)#redistribute rip metric 10
```

Syntax: **redistribute rip** [**metric** <num>] [**route-map** <map-name>]

The **rip** parameter indicates that you are redistributing RIP routes into BGP4.

The **metric** <num> parameter changes the metric. Specify a value from 0 through 4294967295. The default is 0.

The **route-map** <map-name> parameter specifies a route map to be consulted before adding the RIP route to the BGP4 route table.

NOTE

The route map you specify must already be configured on the switch. Refer to [“Defining route maps”](#) on page 1403 for information about defining route maps.

Redistributing OSPF external routes

To configure the Layer 3 switch to redistribute OSPF external type 1 routes, enter the following command.

```
Brocade(config-bgp-router)#redistribute ospf match external1
```

Syntax: **redistribute ospf** [**match internal** | **external1** | **external2**] [**metric** <num>] [**route-map** <map-name>]

The **ospf** parameter indicates that you are redistributing OSPF routes into BGP4.

The **match internal** | **external1** | **external2** parameter applies only to OSPF. This parameter specifies the types of OSPF routes to be redistributed into BGP4. The default is internal.

NOTE

If you do not enter a value for the **match** parameter, (for example, you enter **redistribute ospf** only) then only internal OSPF routes will be redistributed.

The **metric** <num> parameter changes the metric. Specify a value from 0 through 4294967295. The default is 0.

The **route-map** <map-name> parameter specifies a route map to be consulted before adding the OSPF route to the BGP4 route table.

NOTE

The route map you specify must already be configured on the switch. Refer to [“Defining route maps”](#) on page 1403 for information about defining route maps.

NOTE

If you use both the **redistribute ospf route-map** <map-name> command and the **redistribute ospf match internal** | **external1** | **external2** command, the software uses only the route map for filtering.

Redistributing static routes

To configure the Layer 3 switch to redistribute static routes, enter the following command.

```
Brocade(config-bgp-router)#redistribute static
```

Syntax: **redistribute static** [**metric** <num>] [**route-map** <map-name>]

The **static** parameter indicates that you are redistributing static routes into BGP4.

The **metric** <num> parameter changes the metric. Specify a value from 0 through 4294967295. The default is 0.

The **route-map** <map-name> parameter specifies a route map to be consulted before adding the static route to the BGP4 route table.

NOTE

The route map you specify must already be configured on the switch. Refer to [“Defining route maps”](#) on page 1403 for information about defining route maps.

Disabling or re-enabling re-advertisement of all learned BGP4 routes to all BGP4 neighbors

By default, the Layer 3 switch re-advertises all learned best BGP4 routes to BGP4 neighbors, unless the routes are discarded or blocked by route maps or other filters.

If you want to prevent the Layer 3 switch from re-advertising a learned best BGP4 route unless that route also is installed in the IP route table, use the following CLI method.

To disable re-advertisement of BGP4 routes to BGP4 neighbors except for routes that the software also installs in the route table, enter the following command.

```
Brocade(config-bgp-router)#no readvertise
```

Syntax: [**no**] **readvertise**

To re-enable re-advertisement, enter the following command.

```
Brocade(config-bgp-router)#readvertise
```

Redistributing IBGP routes into RIP and OSPF

By default, the Layer 3 switch does not redistribute IBGP routes from BGP4 into RIP or OSPF. This behavior helps eliminate routing loops. However, if your network can benefit from redistributing the IBGP routes from BGP4 into OSPF or RIP, you can enable the Layer 3 switch to redistribute the routes. To do so, use the following CLI method.

To enable the Layer 3 switch to redistribute BGP4 routes into OSPF and RIP, enter the following command.

```
Brocade(config-bgp-router)#bgp-redistribute-internal
```

Syntax: [**no**] **bgp-redistribute-internal**

To disable redistribution of IBGP routes into RIP and OSPF, enter the following command.

```
Brocade(config-bgp-router)#no bgp-redistribute-internal
```

Filtering

This section describes the following:

- [“Specific IP address filtering”](#) on page 1394
- [“AS-path filtering”](#) on page 1395
- [“BGP4 filtering communities”](#) on page 1399
- [“Defining IP prefix lists”](#) on page 1401
- [“Defining neighbor distribute lists”](#) on page 1402
- [“Defining route maps”](#) on page 1403
- [“Using a table map to set the rag value”](#) on page 1411
- [“Configuring cooperative BGP4 route filtering”](#) on page 1411

Specific IP address filtering

You can configure the router to explicitly permit or deny specific IP addresses received in updates from BGP4 neighbors by defining IP address filters. The router permits all IP addresses by default. You can define up to 100 IP address filters for BGP4.

- If you want **permit** to remain the default behavior, define individual filters to deny specific IP addresses.
- If you want to change the default behavior to **deny**, define individual filters to permit specific IP addresses.

NOTE

Once you define a filter, the default action for addresses that do not match a filter is “deny”. To change the default action to “permit”, configure the last filter as “permit any any”.

Address filters can be referred to by a BGP neighbor's distribute list number as well as by match statements in a route map.

NOTE

If the filter is referred to by a route map match statement, the filter is applied in the order in which the filter is listed in the match statement.

NOTE

You also can filter on IP addresses by using IP ACLs.

To define an IP address filter to deny routes to 209.157.0.0, enter the following command.

```
Brocade(config-bgp-router)#address-filter 1 deny 209.157.0.0 255.255.0.0
```

Syntax: `address-filter <num> permit | deny <ip-addr> <wildcard> <mask> <wildcard>`

The `<num>` parameter is the filter number.

The **permit** | **deny** parameter indicates the action the Layer 3 switch takes if the filter match is true.

- If you specify **permit**, the Layer 3 switch permits the route into the BGP4 table if the filter match is true.
- If you specify **deny**, the Layer 3 switch denies the route from entering the BGP4 table if the filter match is true.

NOTE

Once you define a filter, the default action for addresses that do not match a filter is “deny”. To change the default action to “permit”, configure the last filter as “permit any any”.

The `<ip-addr>` parameter specifies the IP address. If you want the filter to match on all addresses, enter **any**.

The `<wildcard>` parameter specifies the portion of the IP address to match against. The `<wildcard>` is in dotted-decimal notation (IP address format). It is a four-part value, where each part is 8 bits (one byte) separated by dots, and each bit is a one or a zero. Each part is a number ranging from 0 to 255, for example 0.0.0.255. Zeros in the mask mean the packet source address must match the `<source-ip>`. Ones mean any value matches. For example, the `<ip-addr>` and `<wildcard>` values 209.157.22.26 0.0.0.255 mean that all hosts in the Class C subnet 209.157.22.x match the policy.

If you prefer to specify the wildcard (mask value) in Classless Interdomain Routing (CIDR) format, you can enter a forward slash after the IP address, then enter the number of significant bits in the mask. For example, you can enter the CIDR equivalent of “209.157.22.26 0.0.0.255” as “209.157.22.26/24”. The CLI automatically converts the CIDR number into the appropriate mask (where zeros instead of ones are the significant bits) and changes the non-significant portion of the IP address into zeros. For example, if you specify 209.157.22.26/24 or 209.157.22.26 0.0.0.255, then save the changes to the startup-config file, the value appears as 209.157.22.0/24 (if you have enabled display of subnet lengths) or 209.157.22.0 0.0.0.255 in the startup-config file.

If you enable the software to display IP subnet masks in CIDR format, the mask is saved in the file in “/`<mask-bits>`” format. To enable the software to display the CIDR masks, enter the **ip show-subnet-length** command at the global CONFIG level of the CLI. You can use the CIDR format to configure the filter regardless of whether the software is configured to display the masks in CIDR format.

The `<mask>` parameter specifies the network mask. If you want the filter to match on all destination addresses, enter **any**. The wildcard works the same as described above.

AS-path filtering

You can filter updates received from BGP4 neighbors based on the contents of the AS-path list accompanying the updates. For example, if you want to deny routes that have the AS 4.3.2.1 in the AS-path from entering the BGP4 route table, you can define a filter to deny such routes.

The Layer 3 switch provides the following methods for filtering on AS-path information:

- AS-path filters
- AS-path ACLs

NOTE

The Layer 3 switch cannot actively support AS-path filters and AS-path ACLs at the same time. Use one method or the other but do not mix methods.

NOTE

Once you define a filter or ACL, the default action for updates that do not match a filter is “deny”. To change the default action to “permit”, configure the last filter or ACL as “permit any any”.

AS-path filters or AS-path ACLs can be referred to by a BGP neighbor's filter list number as well as by match statements in a route map.

Defining an AS-path filter

To define AS-path filter 4 to permit AS 2500, enter the following command.

```
Brocade(config-bgp-router)#as-path-filter 4 permit 2500
```

Syntax: `as-path-filter <num> permit | deny <as-path>`

The `<num>` parameter identifies the filter position in the AS-path filter list and can be from 1 through 100. Thus, the AS-path filter list can contain up to 100 filters. The Brocade Layer 3 switch applies the filters in numerical order, beginning with the lowest-numbered filter. When a filter match is true, the Layer 3 switch stops and does not continue applying filters from the list.

NOTE

If the filter is referred to by a route map match statement, the filter is applied in the order in which the filter is listed in the match statement.

The `permit | deny` parameter indicates the action the router takes if the filter match is true.

- If you specify **permit**, the router permits the route into the BGP4 table if the filter match is true.
- If you specify **deny**, the router denies the route from entering the BGP4 table if the filter match is true.

The `<as-path>` parameter indicates the AS-path information. You can enter an exact AS-path string if you want to filter for a specific value. You also can use regular expressions in the filter string.

Defining an AS-path ACL

To configure an AS-path list that uses ACL 1, enter a command such as the following.

```
Brocade(config)#ip as-path access-list 1 permit 100
Brocade(config)#router bgp
Brocade(config-bgp-router)#neighbor 10.10.10.1 filter-list 1 in
```

The `ip as-path` command configures an AS-path ACL that permits routes containing AS number 100 in their AS paths. The `neighbor` command then applies the AS-path ACL to advertisements and updates received from neighbor 10.10.10.1. In this example, the only routes the Layer 3 switch permits from neighbor 10.10.10.1 are those whose AS-paths contain AS-path number 100.

Syntax: `ip as-path access-list <string> [seq <seq-value>] deny | permit <regular-expression>`

The `<string>` parameter specifies the ACL name. (If you enter a number, the CLI interprets the number as a text string.)

The `seq <seq-value>` parameter is optional and specifies the AS-path list sequence number. You can configure up to 199 entries in an AS-path list. If you do not specify a sequence number, the software numbers them in increments of 5, beginning with number 5. The software interprets the entries in an AS-path list in numerical order, beginning with the lowest sequence number.

The `deny | permit` parameter specifies the action the software takes if a route AS-path list matches a match statement in this ACL. To configure the AS-path match statements in a route map, use the `match as-path` command. Refer to [“Matching based on AS-path ACL”](#) on page 1406.

The `<regular-expression>` parameter specifies the AS path information you want to permit or deny to routes that match any of the match statements within the ACL. You can enter a specific AS number or use a regular expression. For the regular expression syntax, refer to [“Using regular expressions to filter”](#) on page 1397.

The **neighbor** command uses the **filter-list** parameter to apply the AS-path ACL to the neighbor. Refer to [“Adding BGP4 neighbors”](#) on page 1354.

Using regular expressions to filter

You use a regular expression for the `<as-path>` parameter to specify a single character or multiple characters as a filter pattern. If the AS-path matches the pattern specified in the regular expression, the filter evaluation is true; otherwise, the evaluation is false.

In addition, you can include special characters that influence the way the software matches the AS-path against the filter value.

To filter on a specific single-character value, enter the character for the `<as-path>` parameter. For example, to filter on AS-paths that contain the letter “z”, enter the following command.

```
Brocade(config-bgp-router)#as-path-filter 1 permit z
```

To filter on a string of multiple characters, enter the characters in brackets. For example, to filter on AS-paths that contain “x”, “y”, or “z”, enter the following command.

```
Brocade(config-bgp-router)#as-path-filter 1 permit [xyz]
```

BGP4 special characters

When you enter as single-character expression or a list of characters, you also can use the following special characters. [Table 240](#) on page 1397 lists the special characters. The description for each special character includes an example. Notice that you place some special characters in front of the characters they control but you place other special characters after the characters they control. In each case, the examples show where to place the special character.

TABLE 240 BGP4 special characters for regular expressions

Character	Operation
.	The period matches on any single character, including a blank space. For example, the following regular expression matches for “aa”, “ab”, “ac”, and so on, but not just “a”. a.
*	The asterisk matches on zero or more sequences of a pattern. For example, the following regular expression matches on an AS-path that contains the string “1111” followed by any value: 1111*
+	The plus sign matches on one or more sequences of a pattern. For example, the following regular expression matches on an AS-path that contains a sequence of “g”s, such as “deg”, “degg”, “deggg”, and so on: deg+
?	The question mark matches on zero occurrences or one occurrence of a pattern. For example, the following regular expression matches on an AS-path that contains “dg” or “deg”: de?g
^	A caret (when not used within brackets) matches on the beginning of an input string. For example, the following regular expression matches on an AS-path that begins with “3”: ^3
\$	A dollar sign matches on the end of an input string. For example, the following regular expression matches on an AS-path that ends with “deg”: deg\$

TABLE 240 BGP4 special characters for regular expressions (Continued)

Character	Operation
<code>_</code>	<p>An underscore matches on one or more of the following:</p> <ul style="list-style-type: none"> • <code>,</code> (comma) • <code>{</code> (left curly brace) • <code>}</code> (right curly brace) • <code>(</code> (left parenthesis) • <code>)</code> (right parenthesis) • The beginning of the input string • The end of the input string • A blank space <p>For example, the following regular expression matches on <code>"100"</code> but not on <code>"1002"</code>, <code>"2100"</code>, and so on.</p> <pre>_100_</pre>
<code>[]</code>	<p>Square brackets enclose a range of single-character patterns. For example, the following regular expression matches on an AS-path that contains <code>"1"</code>, <code>"2"</code>, <code>"3"</code>, <code>"4"</code>, or <code>"5"</code>:</p> <pre>[1-5]</pre> <p>You can use the following expression symbols within the brackets. These symbols are allowed only inside the brackets:</p> <ul style="list-style-type: none"> • <code>^</code> – The caret matches on any characters except the ones in the brackets. For example, the following regular expression matches on an AS-path that does not contain <code>"1"</code>, <code>"2"</code>, <code>"3"</code>, <code>"4"</code>, or <code>"5"</code>: <pre>[^1-5]</pre> <ul style="list-style-type: none"> • <code>-</code> – The hyphen separates the beginning and ending of a range of characters. A match occurs if any of the characters within the range is present. See the example above.
<code> </code>	<p>A vertical bar (sometimes called a pipe or a "logical or") separates two alternative values or sets of values. The AS-path can match one or the other value. For example, the following regular expression matches on an AS-path that contains either <code>"abc"</code> or <code>"defg"</code>:</p> <pre>(abc) (defg)</pre> <p>NOTE: The parentheses group multiple characters to be treated as one value. See the following row for more information about parentheses.</p>
<code>()</code>	<p>Parentheses allow you to create complex expressions. For example, the following complex expression matches on <code>"abc"</code>, <code>"abcabc"</code>, or <code>"abcabcabcdefg"</code>, but not on <code>"abcdefgdefg"</code>:</p> <pre>((abc)+) ((defg)?)</pre>

If you want to filter for a special character instead of using the special character as described in [Table 239](#) on page 1351, enter `"\"` (backslash) in front of the character. For example, to filter on AS-path strings containing an asterisk, enter the asterisk portion of the regular expression as `"\"`.

```
Brocade(config-bgp-router)#as-path-filter 2 deny \*
```

To use the backslash as a string character, enter two slashes. For example, to filter on AS-path strings containing a backslash, enter the backslash portion of the regular expression as `"\"`.

```
Brocade(config-bgp-router)#as-path-filter 2 deny \\
```

BGP4 filtering communities

You can filter routes received from BGP4 neighbors based on community names. Use either of the following methods to do so.

A community is an optional attribute that identifies the route as a member of a user-defined class of routes. Community names are arbitrary values made of two five-digit integers joined by a colon. You determine what the name means when you create the community name as one of a route attributes. Each string in the community name can be a number from 0 through 65535.

This format allows you to easily classify community names. For example, a common convention used in community naming is to configure the first string as the local AS and the second string as the unique community within that AS. Using this convention, communities 1:10, 1:20, and 1:30 can be easily identified as member communities of AS 1.

The Layer 3 switch provides the following methods for filtering on community information:

- Community filters
- Community list ACLs

NOTE

The Layer 3 switch cannot actively support community filters and community list ACLs at the same time. Use one method or the other but do not mix methods.

NOTE

Once you define a filter or ACL, the default action for communities that do not match a filter or ACL is “deny”. To change the default action to “permit”, configure the last filter or ACL entry as “permit any any”.

Community filters or ACLs can be referred to by match statements in a route map.

Defining a community filter

To define filter 3 to permit routes that have the NO_ADVERTISE community, enter the following command.

```
Brocade(config-bgp-router)#community-filter 3 permit no-advertise
```

Syntax: **community-filter** <num> **permit** | **deny** <num>:<num> | **internet** | **local-as** | **no-advertise** | **no-export**

The <num> parameter identifies the filter position in the community filter list and can be from 1 through 100. Thus, the community filter list can contain up to 100 filters. The router applies the filters in numerical order, beginning with the lowest-numbered filter. When a filter match is true, the router stops and does not continue applying filters from the list.

NOTE

If the filter is referred to by a route map match statement, the filter is applied in the order in which the filter is listed in the match statement.

The **permit** | **deny** parameter indicates the action the router takes if the filter match is true.

- If you specify **permit**, the router permits the route into the BGP4 table if the filter match is true.
- If you specify **deny**, the router denies the route from entering the BGP4 table if the filter match is true.

The `<num>:<num>` parameter indicates a specific community number to filter. Use this parameter to filter for a private (administrator-defined) community. You can enter up to 20 community numbers with the same command.

If you want to filter for the well-known communities “LOCAL_AS”, “NO_EXPORT” or “NO_ADVERTISE”, use the corresponding keyword (described below).

The **internet** keyword checks for routes that do not have the community attribute. Routes without a specific community are considered by default to be members of the largest community, the Internet.

The **local-as** keyword checks for routes with the well-known community “LOCAL_AS”. This community applies only to confederations. The Layer 3 switch advertises the route only within the sub-AS. For information about confederations, refer to [“Configuration notes for BGP4 autonomous systems”](#) on page 1381.

The **no-advertise** keyword filters for routes with the well-known community “NO_ADVERTISE”. A route in this community should not be advertised to any BGP4 neighbors.

The **no-export** keyword filters for routes with the well-known community “NO_EXPORT”. A route in this community should not be advertised to any BGP4 neighbors outside the local AS. If the router is a member of a confederation, the Layer 3 switch advertises the route only within the confederation. For information about confederations, refer to [“Configuration notes for BGP4 autonomous systems”](#) on page 1381.

Defining a community ACL

To configure community ACL 1, enter a command such as the following.

```
Brocade(config)#ip community-list 1 permit 123:2
```

This command configures a community ACL that permits routes that contain community 123:2.

NOTE

Refer to [“Matching based on community ACL”](#) on page 1406 for information about how to use a community list as a match condition in a route map.

Syntax: `ip community-list standard <string> [seq <seq-value>] deny | permit <community-num>`

Syntax: `ip community-list extended <string> [seq <seq-value>] deny | permit <community-num> | <regular-expression>`

The `<string>` parameter specifies the ACL name. (If you enter a number, the CLI interprets the number as a text string.)

The **standard** or **extended** parameter specifies whether you are configuring a standard community ACL or an extended one. A standard community ACL does not support regular expressions whereas an extended one does. This is the only difference between standard and extended IP community lists.

The **seq** `<seq-value>` parameter is optional and specifies the community list sequence number. You can configure up to 199 entries in a community list. If you do not specify a sequence number, the software numbers them in increments of 5, beginning with number 5. The software interprets the entries in a community list in numerical order, beginning with the lowest sequence number.

The **deny** | **permit** parameter specifies the action the software takes if a route community list matches a match statement in this ACL. To configure the community-list match statements in a route map, use the **match community** command. Refer to [“Matching based on community ACL”](#) on page 1406.

The `<community-num>` parameter specifies the community type or community number. This parameter can have the following values:

- `<num>:<num>` – A specific community number
- **internet** – The Internet community
- **no-export** – The community of sub-autonomous systems within a confederation. Routes with this community can be exported to other sub-autonomous systems within the same confederation but cannot be exported outside the confederation to other autonomous systems or otherwise sent to EBGp neighbors.
- **local-as** – The local sub-AS within the confederation. Routes with this community can be advertised only within the local subAS.
- **no-advertise** – Routes with this community cannot be advertised to any other BGP4 routers at all.

The `<regular-expression>` parameter specifies a regular expression for matching on community names. For information about regular expression syntax, refer to [“Using regular expressions to filter”](#) on page 1397. You can specify a regular expression only in an extended community ACL.

Defining IP prefix lists

An IP prefix list specifies a list of networks. When you apply an IP prefix list to a neighbor, the Layer 3 switch sends or receives only a route whose destination is in the IP prefix list. You can configure up to 100 prefix lists. The software interprets the prefix lists in order, beginning with the lowest sequence number.

To configure an IP prefix list and apply it to a neighbor, enter commands such as the following.

```
Brocade(config)#ip prefix-list Routesfor20 permit 20.20.0.0/24
Brocade(config)#router bgp
Brocade(config-bgp-router)#neighbor 10.10.10.1 prefix-list Routesfor20 out
```

These commands configure an IP prefix list named Routesfor20, which permits routes to network 20.20.0.0/24. The **neighbor** command configures the Layer 3 switch to use IP prefix list Routesfor20 to determine which routes to send to neighbor 10.10.10.1. The Layer 3 switch sends routes that go to 20.20.x.x to neighbor 10.10.10.1 because the IP prefix list explicitly permits these routes to be sent to the neighbor.

Syntax: `ip prefix-list <name> [seq <seq-value>] [description <string>] deny | permit <network-addr>/<mask-bits> [ge <ge-value>] [le <le-value>]`

The `<name>` parameter specifies the prefix list name. You use this name when applying the prefix list to a neighbor.

The **description** `<string>` parameter is a text string describing the prefix list.

The **seq** `<seq-value>` parameter is optional and specifies the IP prefix list sequence number. You can configure up to 100 prefix list entries. If you do not specify a sequence number, the software numbers them in increments of 5, beginning with prefix list entry 5. The software interprets the prefix list entries in numerical order, beginning with the lowest sequence number.

The **deny** | **permit** parameter specifies the action the software takes if a neighbor route is in this prefix list.

The prefix-list matches only on this network unless you use the **ge** <ge-value> or **le** <le-value> parameters. (See below.)

The <network-addr>/<mask-bits> parameter specifies the network number and the number of bits in the network mask.

You can specify a range of prefix length for prefixes that are more specific than <network-addr>/<mask-bits>.

- If you specify only **ge** <ge-value>, then the mask-length range is from <ge-value> to 32.
- If you specify only **le** <le-value>, then the mask-length range is from length to <le-value>.

The <ge-value> or <le-value> you specify must meet the following condition.

length < ge-value <= le-value <= 32

If you do not specify **ge** <ge-value> or **le** <le-value>, the prefix list matches only on the exact network prefix you specify with the <network-addr>/<mask-bits> parameter.

For the syntax of the **neighbor** command shown in the example above, refer to [“Adding BGP4 neighbors”](#) on page 1354.

Defining neighbor distribute lists

A neighbor distribute list is a list of BGP4 address filters or ACLs that filter the traffic to or from a neighbor. To configure a neighbor distribute list, use either of the following methods.

To configure a distribute list that uses ACL 1, enter a command such as the following.

```
Brocade(config-bgp-router)#neighbor 10.10.10.1 distribute-list 1 in
```

This command configures the Layer 3 switch to use ACL 1 to select the routes that the Layer 3 switch will accept from neighbor 10.10.10.1.

Syntax: **neighbor** <ip-addr> **distribute-list** <name-or-num> **in** | **out**

The <ip-addr> parameter specifies the neighbor.

The <name-or-num> parameter specifies the name or number of a standard, extended, or named ACL.

The **in** | **out** parameter specifies whether the distribute list applies to inbound or outbound routes:

- **in** – controls the routes the Layer 3 switch will accept from the neighbor.
- **out** – controls the routes sent to the neighbor.

NOTE

The command syntax shown above is new. However, the **neighbor** <ip-addr> **distribute-list in** | **out** <num> command (where the direction is specified before the filter number) is the same as in earlier software releases. Use the new syntax when you are using an IP ACL with the distribute list. Use the old syntax when you are using a BGP4 address filter with the distribute list.

Defining route maps

A **route map** is a named set of match conditions and parameter settings that the router can use to modify route attributes and to control redistribution of the routes into other protocols. A route map consists of a sequence of up to 50 **instances**. If you think of a route map as a table, an instance is a row in that table. The router evaluates a route according to a route map instances in ascending numerical order. The route is first compared against instance 1, then against instance 2, and so on. As soon as a match is found, the router stops evaluating the route against the route map instances.

Route maps can contain **match** statements and **set** statements. Each route map contains a “permit” or “deny” action for routes that match the match statements:

- If the route map contains a permit action, a route that matches a match statement is permitted; otherwise, the route is denied.
- If the route map contains a deny action, a route that matches a match statement is denied.
- If a route does not match any match statements in the route map, the route is denied. This is the default action. To change the default action, configure the last match statement in the last instance of the route map to “permit any any”.
- If there is no match statement, the software considers the route to be a match.
- For route maps that contain address filters, AS-path filters, or community filters, if the action specified by a filter conflicts with the action specified by the route map, the route map action takes precedence over the individual filter action.

If the route map contains set statements, routes that are permitted by the route map match statements are modified according to the set statements.

Match statements compare the route against one or more of the following:

- The route BGP4 MED (metric)
- A sequence of AS-path filters
- A sequence of community filters
- A sequence of address filters
- The IP address of the next hop router
- The route tag
- For OSPF routes only, the route type (internal, external type-1, or external type-2)
- An AS-path ACL
- A community ACL
- An IP prefix list
- An IP ACL

For routes that match all of the match statements, the route map set statements can perform one or more of the following modifications to the route attributes:

- Prepend AS numbers to the front of the route AS-path. By adding AS numbers to the AS-path, you can cause the route to be less preferred when compared to other routes on the basis of the length of the AS-path.
- Add a user-defined tag to the route or add an automatically calculated tag to the route.
- Set the community value.
- Set the local preference.

- Set the MED (metric).
- Set the IP address of the next hop router.
- Set the origin to IGP or INCOMPLETE.
- Set the weight.

For example, when you configure parameters for redistributing routes into RIP, one of the optional parameters is a route map. If you specify a route map as one of the redistribution parameters, the router will match the route against the match statements in the route map. If a match is found and if the route map contains set statements, the router will set attributes in the route according to the set statements.

To create a route map, you define instances of the map. Each instance is identified by a sequence number. A route map can contain up to 50 instances.

To define a route map, use the procedures in the following sections.

Entering the route map into the software

To add instance 1 of a route map named “GET_ONE” with a permit action, enter the following command.

```
Brocade(config)#route-map GET_ONE permit 1
Brocade(config-route-map GET_ONE)#
```

Syntax: [no] route-map <map-name> permit | deny <num>

As shown in this example, the command prompt changes to the Route Map level. You can enter the match and set statements at this level. Refer to [“Specifying the match conditions”](#) on page 1405 and [“Setting parameters in the routes”](#) on page 1408.

The <map-name> is a string of characters that names the map. Map names can be up to 32 characters in length.

The **permit** | **deny** parameter specifies the action the router will take if a route matches a match statement.

- If you specify **deny**, the Layer 3 switch does not advertise or learn the route.
- If you specify **permit**, the Layer 3 switch applies the match and set statements associated with this route map instance.

The <num> parameter specifies the instance of the route map you are defining. Each route map can have up to 50 instances.

To delete a route map, enter a command such as the following. When you delete a route map, all the permit and deny entries in the route map are deleted.

```
Brocade(config)#no route-map Map1
```

This command deletes a route map named “Map1”. All entries in the route map are deleted.

To delete a specific instance of a route map without deleting the rest of the route map, enter a command such as the following.

```
Brocade(config)#no route-map Map1 permit 10
```

This command deletes the specified instance from the route map but leaves the other instances of the route map intact.

Specifying the match conditions

Use the following command to define the match conditions for instance 1 of the route map GET_ONE. This instance compares the route updates against BGP4 address filter 11.

```
Brocade(config-routemap GET_ONE)#match address-filters 11
```

Syntax: **match** [**as-path** <num>] | [**address-filters** | **as-path-filters** | **community-filters** <num,num,...>] | [**community** <num>] | [**community** <ACL> **exact-match**] | [**ip address** <ACL> | **prefix-list** <string>] | [**ip route-source** <ACL> | **prefix** <name>] [**metric** <num>] | [**next-hop** <address-filter-list>] | [**nlri multicast** | **unicast** | **multicast unicast**] | [**route-type internal** | **external-type1** | **external-type2**] | [**tag** <tag-value>]

The **as-path** <num> parameter specifies an AS-path ACL. You can specify up to five AS-path ACLs. To configure an AS-path ACL, use the **ip as-path access-list** command. Refer to [“Defining an AS-path ACL”](#) on page 1396.

The **address-filters** | **as-path-filters** | **community-filters** <num,num,...> parameter specifies a filter or list of filters to be matched for each route. The router treats the first match as the best match. If a route does not match any filter in the list, then the router considers the match condition to have failed. To configure these types of filters, use commands at the BGP configuration level:

- To configure an address filter, refer to [“Specific IP address filtering”](#) on page 1394.
- To configure an AS-path filter or AS-path ACL, refer to [“AS-path filtering”](#) on page 1395.
- To configure a community filter or community ACL, refer to [“BGP4 filtering communities”](#) on page 1399.

You can enter up to six community names on the same command line.

NOTE

The filters must already be configured.

The **community** <num> parameter specifies a community ACL.

NOTE

The ACL must already be configured.

The **community** <ACL> **exact-match** parameter matches a route if (and only if) the route's community attributes field contains the same community numbers specified in the match statement.

The **ip address** | **next-hop** <ACL-num> | **prefix-list** <string> parameter specifies an ACL or IP prefix list. Use this parameter to match based on the destination network or next-hop gateway. To configure an IP ACL for use with this command, use the **ip access-list** command. Refer to [“ACL overview”](#) on page 1705. To configure an IP prefix list, use the **ip prefix-list** command. Refer to [“Defining IP prefix lists”](#) on page 1401.

The **ip route-source** <ACL> | **prefix** <name> parameter matches based on the source of a route (the IP address of the neighbor from which the Brocade device learned the route).

The **metric** <num> parameter compares the route MED (metric) to the specified value.

The **next-hop** <address-filter-list> parameter compares the IP address of the route next hop to the specified IP address filters. The filters must already be configured.

The **nlri multicast** | **unicast** | **multicast unicast** parameter specifies whether you want the route map to match on multicast routes, unicast routes, or both route types.

NOTE

By default, route maps apply to both unicast and multicast traffic.

The **route-type internal | external-type1 | external-type2** parameter applies only to OSPF routes. This parameter compares the route type to the specified value.

The **tag <tag-value>** parameter compares the route tag to the specified value.

Match examples using ACLs

The following sections show some detailed examples of how to configure route maps that include match statements that match on ACLs.

Matching based on AS-path ACL

To construct a route map that matches based on AS-path ACL 1, enter the following commands.

```
Brocade(config)#route-map PathMap permit 1
Brocade(config-routemap PathMap)#match as-path 1
```

Syntax: **match as-path <num>**

The **<num>** parameter specifies an AS-path ACL and can be a number from 1 through 199. You can specify up to five AS-path ACLs. To configure an AS-path ACL, use the **ip as-path access-list** command. Refer to [“Defining an AS-path ACL”](#) on page 1396.

Matching based on community ACL

To construct a route map that matches based on community ACL 1, enter the following commands.

```
Brocade(config)#ip community-list 1 permit 123:2
Brocade(config)#route-map CommMap permit 1
Brocade(config-routemap CommMap)#match community 1
```

Syntax: **match community <string>**

The **<string>** parameter specifies a community list ACL. To configure a community list ACL, use the **ip community-list** command. Refer to [“Defining a community ACL”](#) on page 1400.

Matching based on destination network

To construct match statements for a route map that match based on destination network, use the following method. You can use the results of an IP ACL or an IP prefix list as the match condition.

```
Brocade(config)#route-map NetMap permit 1
Brocade(config-routemap NetMap)#match ip address 1
```

Syntax: **match ip address <name-or-num>**

Syntax: **match ip address prefix-list <name>**

The **<name-or-num>** parameter with the first command specifies an IP ACL and can be a number from 1 through 199 or the ACL name if it is a named ACL. To configure an IP ACL, use the **ip access-list** or **access-list** command. Refer to [Chapter 40, “Rule-Based IP ACLs”](#).

The **<name>** parameter with the second command specifies an IP prefix list name. To configure an IP prefix list, refer to [“Defining IP prefix lists”](#) on page 1401.

Matching based on next-hop router

To construct match statements for a route map that match based on the IP address of the next-hop router, use either of the following methods. You can use the results of an IP ACL or an IP prefix list as the match condition.

To construct a route map that matches based on the next-hop router, enter commands such as the following.

```
Brocade(config)#route-map HopMap permit 1
Brocade(config-route-map HopMap)#match ip next-hop 2
```

Syntax: `match ip next-hop <num>`

Syntax: `match ip next-hop prefix-list <name>`

The `<num>` parameter with the first command specifies an IP ACL and can be a number from 1 through 199 or the ACL name if it is a named ACL. To configure an IP ACL, use the `ip access-list` or `access-list` command. Refer to [Chapter 40, “Rule-Based IP ACLs”](#).

The `<name>` parameter with the second command specifies an IP prefix list name. To configure an IP prefix list, refer to [“Defining IP prefix lists”](#) on page 1401.

Matching based on the route source

To match a BGP4 route based on its source, use the `match ip route-source` statement. Here is an example.

```
Brocade(config)#access-list 10 permit 192.168.6.0 0.0.0.255
Brocade(config)#route-map bgp1 permit 1
Brocade(config-route-map bgp1)#match ip route-source 10
```

The first command configures an IP ACL that matches on routes received from 192.168.6.0/24. The remaining commands configure a route map that matches on all BGP4 routes advertised by the BGP4 neighbors whose addresses match addresses in the IP prefix list. You can add a set statement to change a route attribute in the routes that match. You also can use the route map as input for other commands, such as the `neighbor` and `network` commands and some `show` commands.

Syntax: `match ip route-source <ACL> | prefix <name>`

The `<ACL> | prefix <name>` parameter specifies the name or ID of an IP ACL, or an IP prefix list.

Matching on routes containing a specific set of communities

Brocade software enables you to match routes based on the presence of a community name or number in a route, and to match when a route contains exactly the set of communities you specify. To match based on a set of communities, configure a community ACL that lists the communities, then compare routes against the ACL, as shown in the following example.

```
Brocade(config)#ip community-list standard std_1 permit 12:34 no-export
Brocade(config)#route-map bgp2 permit 1
Brocade(config-route-map bgp2)#match community std_1 exact-match
```

The first command configures a community ACL that contains community number 12:34 and community name no-export. The remaining commands configure a route map that matches the community attributes field in BGP4 routes against the set of communities in the ACL. A route matches the route map only if the route contains all the communities in the ACL and no other communities.

Syntax: `match community <ACL> exact-match`

The `<ACL>` parameter specifies the name of a community list ACL. You can specify up to five ACLs. Separate the ACL names or IDs with spaces.

Here is another example.

```
Brocade(config)#ip community-list standard std_2 permit 23:45 56:78
Brocade(config)#route-map bgp3 permit 1
Brocade(config-route-map bgp3)#match community std_1 std_2 exact-match
```

These commands configure an additional community ACL, `std_2`, that contains community numbers 23:45 and 57:68. Route map `bgp3` compares each BGP4 route against the sets of communities in ACLs `std_1` and `std_2`. A BGP4 route that contains **either but not both** sets of communities matches the route map. For example, a route containing communities 23:45 and 57:68 matches. However, a route containing communities 23:45, 57:68 and 12:34, or communities 23:45, 57:68, 12:34, and no-export does not match. To match, the route communities must be the same as those in exactly one of the community ACLs used by the match community statement.

Setting parameters in the routes

Use the following command to define a set statement that prepends an AS number to the AS path on each route that matches the corresponding match statement.

```
Brocade(config-route-map GET_ONE)#set as-path prepend 65535
```

Syntax: `set [as-path [prepend <as-num,as-num,...>]] | [automatic-tag] | [comm-list <ACL> delete] | [community <num>:<num> | <num> | internet | local-as | no-advertise | no-export] | [dampening [<half-life> <reuse> <suppress> <max-suppress-time>]] [[default] interface null0 | [ip [default] next hop <ip-addr>] [ip next-hop peer-address] | [local-preference <num>] | [metric [+ | -]<num> | none] | [metric-type type-1 | type-2] | [metric-type internal] | [next-hop <ip-addr>] | [nlri multicast | unicast | multicast unicast] | [origin igp | incomplete] | [tag <tag-value>] | [weight <num>]`

The **as-path prepend** `<num,num,...>` parameter adds the specified AS numbers to the front of the AS-path list for the route.

The **automatic-tag** parameter calculates and sets an automatic tag value for the route.

NOTE

This parameter applies only to routes redistributed into OSPF.

The **comm-list** parameter deletes a community from a BGP4 route community attributes field.

The **community** parameter sets the community attribute for the route to the number or well-known type you specify.

The **dampening** `[<half-life> <reuse> <suppress> <max-suppress-time>]` parameter sets route dampening parameters for the route. The `<half-life>` parameter specifies the number of minutes after which the route penalty becomes half its value. The `<reuse>` parameter specifies how low a route penalty must become before the route becomes eligible for use again after being suppressed. The `<suppress>` parameter specifies how high a route penalty can become before the Layer 3 switch suppresses the route. The `<max-suppress-time>` parameter specifies the maximum number of minutes that a route can be suppressed regardless of how unstable it is. For information and examples, refer to [“Route flap dampening configuration”](#) on page 1414.

The **[default] interface null0** parameter redirects the traffic to the specified interface. You can send the traffic to the null0 interface, which is the same as dropping the traffic. You can specify more than one interface, in which case the Layer 3 switch uses the first available port. If the first port is unavailable, the Layer 3 switch sends the traffic to the next port in the list. If you specify **default**, the route map redirects the traffic to the specified interface only if the Layer 3 switch does not already have explicit routing information for the traffic. This option is used in Policy-Based Routing (PBR).

The **ip [default] next hop <ip-addr>** parameter sets the next-hop IP address for traffic that matches a match statement in the route map. If you specify **default**, the route map sets the next-hop gateway only if the Layer 3 switch does not already have explicit routing information for the traffic. This option is used in Policy-Based Routing (PBR).

The **ip next-hop peer-address** parameter sets the BGP4 next hop for a route to the specified neighbor address.

The **local-preference <num>** parameter sets the local preference for the route. You can set the preference to a value from 0 through 4294967295.

The **metric [+ | -]<num> | none** parameter sets the MED (metric) value for the route. The default MED value is 0. You can set the preference to a value from 0 through 4294967295.

- **set metric <num>** – Sets the route metric to the number you specify.
- **set metric +<num>** – Increases route metric by the number you specify.
- **set metric -<num>** – Decreases route metric by the number you specify.
- **set metric none** – Removes the metric from the route (removes the MED attribute from the BGP4 route).

The **metric-type type-1 | type-2** parameter changes the metric type of a route redistributed into OSPF.

The **metric-type internal** parameter sets the route's MED to the same value as the IGP metric of the BGP4 next-hop route. The parameter does this when advertising a BGP4 route to an EBGp neighbor.

The **next-hop <ip-addr>** parameter sets the IP address of the route next hop router.

The **nlri multicast | unicast | multicast unicast** parameter redistributes routes into the multicast Routing Information Base (RIB) instead of the unicast RIB.

NOTE

Setting the NLRI type to multicast applies only when you are using the route map to redistribute directly-connected routes. Otherwise, the set option is ignored.

The **origin igp | incomplete** parameter sets the route origin to IGP or INCOMPLETE.

The **tag <tag-value>** parameter sets the route tag. You can specify a tag value from 0 through 4294967295.

NOTE

This parameter applies only to routes redistributed into OSPF.

NOTE

You also can set the tag value using a table map. The table map changes the value only when the Layer 3 switch places the route in the IP route table instead of changing the value in the BGP route table. Refer to [“Using a table map to set the tag value”](#) on page 1411.

The **weight** <num> parameter sets the weight for the route. You can specify a weight value from 0 through 4294967295.

Setting a BGP4 route MED to the same value as the IGP metric of the next-hop route

To set a route's MED to the same value as the IGP metric of the BGP4 next-hop route, when advertising the route to a neighbor, enter commands such as the following.

```
Brocade(config)#access-list 1 permit 192.168.9.0 0.0.0.255
Brocade(config)#route-map bgp4 permit 1
Brocade(config-route-map bgp4)#match ip address 1
Brocade(config-route-map bgp4)#set metric-type internal
```

The first command configures an ACL that matches on routes with destination network 192.168.9.0. The remaining commands configure a route map that matches on the destination network in ACL 1, then sets the metric type for those routes to the same value as the IGP metric of the BGP4 next-hop route.

Syntax: **set metric-type internal**

Setting the next hop of a BGP4 route

To set the next hop address of a BGP4 route to a neighbor address, enter commands such as the following.

```
Brocade(config)#route-map bgp5 permit 1
Brocade(config-route-map bgp5)#match ip address 1
Brocade(config-route-map bgp5)#set ip next-hop peer-address
```

These commands configure a route map that matches on routes whose destination network is specified in ACL 1, and sets the next hop in the routes to the neighbor address (inbound filtering) or the local IP address of the BGP4 session (outbound filtering).

Syntax: **set ip next-hop peer-address**

The value that the software substitutes for **peer-address** depends on whether the route map is used for inbound filtering or outbound filtering:

- When you use the **set ip next-hop peer-address** command in an inbound route map filter, **peer-address** substitutes for the neighbor IP address.
- When you use the **set ip next-hop peer-address** command in an outbound route map filter, **peer-address** substitutes for the local IP address of the BGP4 session.

NOTE

You can use this command for a peer group configuration.

Deleting a community from a BGP4 route

To delete a community from a BGP4 route community attributes field, enter commands such as the following.

```
Brocade(config)#ip community-list standard std_3 permit 12:99 12:86
Brocade(config)#route-map bgp6 permit 1
Brocade(config-route-map bgp6)#match ip address 1
Brocade(config-route-map bgp6)#set comm-list std_3 delete
```

The first command configures a community ACL containing community numbers 12:99 and 12:86. The remaining commands configure a route map that matches on routes whose destination network is specified in ACL 1, and deletes communities 12:99 and 12:86 from those routes. The route does not need to contain all the specified communities in order for them to be deleted. For example, if a route contains communities 12:86, 33:44, and 66:77, community 12:86 is deleted.

Syntax: `set comm-list <ACL> delete`

The <ACL> parameter specifies the name of a community list ACL.

Using a table map to set the tag value

Route maps that contain set statements change values in routes when the routes are accepted by the route map. For inbound route maps (route maps that filter routes received from neighbors), this means that the routes are changed before they enter the BGP4 route table.

For tag values, if you do not want the value to change until a route enters the IP route table, you can use a table map to change the value. A table map is a route map that you have associated with the IP routing table. The Layer 3 switch applies the set statements for tag values in the table map to routes before adding them to the route table.

To configure a table map, you configure the route map, then identify it as a table map. The table map does not require separate configuration. You create it simply by calling an existing route map a table map. You can have one table map.

NOTE

Use table maps only for setting the tag value. Do not use table maps to set other attributes. To set other route attributes, use route maps or filters.

To create a route map and identify it as a table map, enter commands such as following. These commands create a route map that uses an address filter. For routes that match the address filter, the route map changes the tag value to 100. This route map is then identified as a table map. As a result, the route map is applied only to routes that the Layer 3 switch places in the IP route table. The route map is not applied to all routes. This example assumes that address filter 11 has already been configured.

```
Brocade(config)#route-map TAG_IP permit 1
Brocade(config-routemap TAG_IP)#match address-filters 11
Brocade(config-routemap TAG_IP)#set tag 100
Brocade(config-routemap TAG_IP)#router bgp
Brocade(config-bgp-router)#table-map TAG_IP
```

Configuring cooperative BGP4 route filtering

By default, the Layer 3 switch performs all filtering of incoming routes locally, on the Layer 3 switch itself. You can use cooperative BGP4 route filtering to cause the filtering to be performed by a neighbor before it sends the routes to the Layer 3 switch. Cooperative filtering conserves resources by eliminating unnecessary route updates and filter processing. For example, the Layer 3 switch can send a deny filter to its neighbor, which the neighbor uses to filter out updates before sending them to the Layer 3 switch. The neighbor saves the resources it would otherwise use to generate the route updates, and the Layer 3 switch saves the resources it would use to filter out the routes.

When you enable cooperative filtering, the Layer 3 switch advertises this capability in its Open message to the neighbor when initiating the neighbor session. The Open message also indicates whether the Layer 3 switch is configured to send filters, receive filters or both, and the types of filters it can send or receive. The Layer 3 switch sends the filters as Outbound Route Filters (ORFs) in Route Refresh messages.

To configure cooperative filtering, perform the following tasks on the Layer 3 switch and on its BGP4 neighbor:

- Configure the filter.

NOTE

The current release supports cooperative filtering only for filters configured using IP prefix lists.

- Apply the filter as in *inbound* filter to the neighbor.
- Enable the cooperative route filtering feature on the Layer 3 switch. You can enable the Layer 3 switch to send ORFs to the neighbor, to receive ORFs from the neighbor, or both. The neighbor uses the ORFs you send as outbound filters when it sends routes to the Layer 3 switch. Likewise, the Layer 3 switch uses the ORFs it receives from the neighbor as outbound filters when sending routes to the neighbor.
- Reset the BGP4 neighbor session to send and receive ORFs.
- Perform these steps on the other device.

NOTE

If the Layer 3 switch has inbound filters, the filters are still processed even if equivalent filters have been sent as ORFs to the neighbor.

Enabling cooperative filtering

To configure cooperative filtering, enter commands such as the following.

```
Brocade(config)#ip prefix-list Routesfrom1234 deny 20.20.0.0/24
Brocade(config)#ip prefix-list Routesfrom1234 permit 0.0.0.0/0 le 32
Brocade(config)#router bgp
Brocade(config-bgp-router)#neighbor 1.2.3.4 prefix-list Routesfrom1234 in
Brocade(config-bgp-router)#neighbor 1.2.3.4 capability orf prefixlist send
```

The first two commands configure statements for the IP prefix list Routesfrom1234. The first command configures a statement that denies routes to 20.20.20./24. The second command configures a statement that permits all other routes. (Once you configure an IP prefix list statement, all routes not explicitly permitted by statements in the prefix list are denied.)

The next two commands change the CLI to the BGP4 configuration level, then apply the IP prefix list to neighbor 1.2.3.4. The last command enables the Layer 3 switch to send the IP prefix list as an ORF to neighbor 1.2.3.4. When the Layer 3 switch sends the IP prefix list to the neighbor, the neighbor filters out the 20.20.0.x routes from its updates to the Layer 3 switch. (This assumes that the neighbor also is configured for cooperative filtering.)

The *<ip-addr> | <peer-group-name>* parameter specifies the IP address of a neighbor or the name of a peer group of neighbors.

The **send** | **receive** parameter specifies the support you are enabling:

- **send** – The Layer 3 switch sends the IP prefix lists to the neighbor.
- **receive** – The Layer 3 switch accepts filters from the neighbor.

If you do not specify the capability, both capabilities are enabled.

The **prefixlist** parameter specifies the type of filter you want to send to the neighbor.

NOTE

The current release supports cooperative filtering only for filters configured using IP prefix lists.

Sending and receiving ORFs

Cooperative filtering affects neighbor sessions that start after the filtering is enabled, but do not affect sessions that are already established.

To activate cooperative filtering, reset the session with the neighbor. This is required because the cooperative filtering information is exchanged in Open messages during the start of a session.

To place a prefix-list change into effect after activating cooperative filtering, perform a soft reset of the neighbor session. A soft reset does not end the current session, but sends the prefix list to the neighbor in the next route refresh message.

NOTE

Make sure cooperative filtering is enabled on the Layer 3 switch and on the neighbor before you send the filters.

To reset a neighbor session and send ORFs to the neighbor, enter a command such as the following.

```
Brocade#clear ip bgp neighbor 1.2.3.4
```

This command resets the BGP4 session with neighbor 1.2.3.4 and sends the ORFs to the neighbor. If the neighbor sends ORFs to the Layer 3 switch, the Layer 3 switch accepts them if the send capability is enabled.

To perform a soft reset of a neighbor session and send ORFs to the neighbor, enter a command such as the following.

```
Brocade#clear ip bgp neighbor 1.2.3.4 soft in prefix-list
```

Syntax: **clear ip bgp neighbor** <ip-addr> [**soft in prefix-filter**]

If you use the **soft in prefix-filter** parameter, the Layer 3 switch sends the updated IP prefix list to the neighbor as part of its route refresh message to the neighbor.

NOTE

If the Layer 3 switch or the neighbor is not configured for cooperative filtering, the command sends a normal route refresh message.

Displaying cooperative filtering information

You can display the following cooperative filtering information:

- The cooperative filtering configuration on the Layer 3 switch.
- The ORFs received from neighbors.

To display the cooperative filtering configuration on the Layer 3 switch, enter a command such as the following. The line shown in bold type shows the cooperative filtering status.

Route flap dampening configuration

```
Brocade#show ip bgp neighbors 10.10.10.1
1  IP Address: 10.10.10.1, AS: 65200 (IBGP), RouterID: 10.10.10.1
   State: ESTABLISHED, Time: 0h0m7s, KeepAliveTime: 60, HoldTime: 180
   RefreshCapability: Received
   CooperativeFilteringCapability: Received

Syntax: show ip bgp neighbors <ip-addr>

To display the ORFs received from a neighbor, enter a command such as the following.

```
Brocade#show ip bgp neighbors 10.10.10.1 received prefix-filter
ip prefix-list 10.10.10.1: 4 entries
  seq 5 permit 10.10.0.0/16 ge 18 le 28
  seq 10 permit 20.20.10.0/24
  seq 15 permit 30.0.0.0/8 le 32
  seq 20 permit 40.10.0.0/16 ge 18
```

Syntax: show ip bgp neighbors <ip-addr> received prefix-filter

Route flap dampening configuration

A “route flap” is the change in a route state, from up to down or down to up. When a route state changes, the state change causes changes in the route tables of the routers that support the route. Frequent changes in a route state can cause Internet instability and add processing overhead to the routers that support the route.

Route flap dampening is a mechanism that reduces the impact of route flap by changing a BGP4 router response to route state changes. When route flap dampening is configured, the Layer 3 switch suppresses unstable routes until the route state changes reduce enough to meet an acceptable degree of stability. The Brocade implementation of route flap dampening is based on RFC 2439.

Route flap dampening is disabled by default. You can enable the feature globally or on an individual route basis using route maps.

NOTE

The Layer 3 switch applies route flap dampening only to routes learned from EBGp neighbors.

The route flap dampening mechanism is based on penalties. When a route exceeds a configured penalty value, the Layer 3 switch stops using that route and also stops advertising it to other routers. The mechanism also allows a route penalties to reduce over time if the route stability improves. The route flap dampening mechanism uses the following parameters:

- **Suppression threshold** – Specifies the penalty value at which the Layer 3 switch stops using the route. Each time a route becomes unreachable or is withdrawn by a BGP4 UPDATE from a neighbor, the route receives a penalty of 1000. By default, when a route has a penalty value greater than 2000, the Layer 3 switch stops using the route. Thus, by default, if a route goes down more than twice, the Layer 3 switch stops using the route. You can set the suppression threshold to a value from 1 through 20000. The default is 2000.
- **Half-life** – Once a route has been assigned a penalty, the penalty decreases exponentially and decreases by half after the half-life period. The default half-life period is 15 minutes. The software reduces route penalties every five seconds. For example, if a route has a penalty of 2000 and does not receive any more penalties (it does not go down again) during the half-life, the penalty is reduced to 1000 after the half-life expires. You can configure the half-life to be from 1 through 45 minutes. The default is 15 minutes.
- **Reuse threshold** – Specifies the minimum penalty a route can have and still be suppressed by the Layer 3 switch. If the route's penalty falls below this value, the Layer 3 switch un-suppresses the route and can use it again. The software evaluates the dampened routes every ten seconds and un-suppresses the routes that have penalties below the reuse threshold. You can set the reuse threshold to a value from 1 through 20000. The default is 750.
- **Maximum suppression time** – Specifies the maximum number of minutes a route can be suppressed regardless of how unstable the route has been before this time. You can set the parameter to a value from 1 through 20000 minutes. The default is four times the half-life. When the half-life value is set to its default (15 minutes), the maximum suppression time defaults to 60 minutes.

You can configure route flap dampening globally or for individual routes using route maps. If you configure route flap dampening parameters globally and also use route maps, the settings in the route maps override the global values.

Globally configuring route flap dampening

To enable route flap dampening using the default values, enter the following command.

```
Brocade(config-bgp-router)#dampening
```

Syntax: `dampening [<half-life> <reuse> <suppress> <max-suppress-time>]`

The `<half-life>` parameter specifies the number of minutes after which the route penalty becomes half its value. The route penalty allows routes that have remained stable for a while despite earlier instability to eventually become eligible for use again. The decay rate of the penalty is proportional to the value of the penalty. After the half-life expires, the penalty decays to half its value. Thus, a dampened route that is no longer unstable can eventually become eligible for use again. You can configure the half-life to be from 1 - 45 minutes. The default is 15 minutes.

The `<reuse>` parameter specifies how low a route penalty must become before the route becomes eligible for use again after being suppressed. You can set the reuse threshold to a value from 1 through 20000. The default is 750 (0.75, or three-fourths, of the penalty assessed for a one "flap").

The `<suppress>` parameter specifies how high a route penalty can become before the Layer 3 switch suppresses the route. You can set the suppression threshold to a value from 1 through 20000. The default is 2000 (two “flaps”).

The `<max-suppress-time>` parameter specifies the maximum number of minutes that a route can be suppressed regardless of how unstable it is. You can set the maximum suppression time to a value from 1 through 20000 minutes. The default is four times the half-life setting. Thus, if you use the default half-life of 15 minutes, the maximum suppression time is 60 minutes.

The following example shows how to change the dampening parameters.

```
Brocade(config-bgp-router)#dampening 20 200 2500 40
```

This command changes the half-life to 20 minutes, the reuse threshold to 200, the suppression threshold to 2500, and the maximum number of minutes a route can be dampened to 40.

NOTE

To change any of the parameters, you must specify all the parameters with the command. If you want to leave some parameters unchanged, enter their default values.

Using a route map to configure route flap dampening for specific routes

Route maps enable you to fine tune route flap dampening parameters for individual routes. To configure route flap dampening parameters using route maps, configure BGP4 address filters for each route you want to set the dampening parameters for, then configure route map entries that set the dampening parameters for those routes. The following sections show examples.

To configure address filters and a route map for dampening specific routes, enter commands such as the following.

```
Brocade(config)#router bgp
Brocade(config-bgp-router)#address-filter 9 permit 209.157.22.0 255.255.255.0
255.255.255.0 255.255.255.0
Brocade(config-bgp-router)#address-filter 10 permit 209.157.23.0 255.255.255.0
255.255.255.0 255.255.255.0
Brocade(config-bgp-router)#exit
Brocade(config)#route-map DAMPENING_MAP permit 9
Brocade(config-routemap DAMPENING_MAP)#match address-filters 9
Brocade(config-routemap DAMPENING_MAP)#set dampening 10 200 2500 40
Brocade(config-routemap DAMPENING_MAP)#exit
Brocade(config)#route-map DAMPENING_MAP permit 10
Brocade(config-routemap DAMPENING_MAP)#match address-filters 10
Brocade(config-routemap DAMPENING_MAP)#set dampening 20 200 2500 60
Brocade(config-routemap DAMPENING_MAP)#router bgp
Brocade(config-bgp-router)#dampening route-map DAMPENING_MAP
```

The **address-filter** commands in this example configure two BGP4 address filters, for networks 209.157.22.0 and 209.157.23.0. The first route-map command creates an entry in a route map called “DAMPENING_MAP”. Within this entry of the route map, the **match** command matches based on address filter 9, and the **set** command sets the dampening parameters for the route that matches. Thus, for BGP4 routes to 209.157.22.0, the Layer 3 switch uses the route map to set the dampening parameters. These parameters override the globally configured dampening parameters.

The commands for the second entry in the route map (instance 10 in this example) perform the same functions for route 209.157.23.0. Notice that the dampening parameters are different for each route.

Using a route map to configure route flap dampening for a specific neighbor

You can use a route map to configure route flap dampening for a specific neighbor by performing the following tasks:

- Configure an empty route map with no match or set statements. This route map does not specify particular routes for dampening but does allow you to enable dampening globally when you refer to this route map from within the BGP configuration level.
- Configure another route map that explicitly enables dampening. Use a set statement within the route map to enable dampening. When you associate this route map with a specific neighbor, the route map enables dampening for all routes associated with the neighbor. You also can use match statements within the route map to selectively perform dampening on some routes from the neighbor.

NOTE

You still need to configure the first route map to enable dampening globally. The second route map does not enable dampening by itself; it just applies dampening to a neighbor.

- Apply the route map to the neighbor.

To enable route flap dampening for a specific BGP4 neighbor, enter commands such as the following.

```
Brocade(config)#route-map DAMPENING_MAP_ENABLE permit 1
Brocade(config-route-map DAMPENING_MAP_ENABLE)#exit
Brocade(config)#route-map DAMPENING_MAP_NEIGHBOR_A permit 1
Brocade(config-route-map DAMPENING_MAP_NEIGHBOR_A)#set dampening
Brocade(config-route-map DAMPENING_MAP_NEIGHBOR_A)#exit
Brocade(config)#router bgp
Brocade(config-bgp-router)#dampening route-map DAMPENING_MAP_ENABLE
Brocade(config-bgp-router)#neighbor 10.10.10.1 route-map in
DAMPENING_MAP_NEIGHBOR_A
```

In this example, the first command globally enables route flap dampening. This route map does not contain any match or set statements. At the BGP configuration level, the **dampening route-map** command refers to the DAMPENING_MAP_ENABLE route map created by the first command, thus enabling dampening globally.

The third and fourth commands configure a second route map that explicitly enables dampening. Notice that the route map does not contain a match statement. The route map implicitly applies to all routes. Since the route map will be applied to a neighbor at the BGP configuration level, the route map will apply to all routes associated with the neighbor.

Although the second route map enables dampening, the first route map is still required. The second route map enables dampening for the neighbors to which the route map is applied. However, unless dampening is already enabled globally by the first route map, the second route map has no effect.

The last two commands apply the route maps. The **dampening route-map** command applies the first route map, which enables dampening globally. The **neighbor** command applies the second route map to neighbor 10.10.10.1. Since the second route map does not contain match statements for specific routes, the route map enables dampening for all routes received from the neighbor.

Removing route dampening from a route

You can un-suppress routes by removing route flap dampening from the routes. The Layer 3 switch allows you to un-suppress all routes at once or un-suppress individual routes.

To un-suppress all the suppressed routes, enter the following command at the Privileged EXEC level of the CLI.

```
Brocade#clear ip bgp damping
```

Syntax: `clear ip bgp damping [<ip-addr> <ip-mask>]`

The `<ip-addr>` parameter specifies a particular network.

The `<ip-mask>` parameter specifies the network mask.

To un-suppress a specific route, enter a command such as the following.

```
Brocade#clear ip bgp damping 209.157.22.0 255.255.255.0
```

This command un-suppresses only the routes for network 209.157.22.0/24.

Removing route dampening from a neighbor routes suppressed due to aggregation

You can selectively unsuppress more-specific routes that have been suppressed due to aggregation, and allow the routes to be advertised to a specific neighbor or peer group.

Here is an example.

```
Brocade(config-bgp-router)#aggregate-address 209.1.0.0 255.255.0.0 summary-only
Brocade(config-bgp-router)#show ip bgp route 209.1.0.0/16 longer
Number of BGP Routes matching display condition : 2
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
      E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
      Prefix          Next Hop          Metric      LocPrf      Weight Status
1      209.1.0.0/16    0.0.0.0              101          32768    BAL
      AS_PATH:
2      209.1.44.0/24   10.2.0.1              1            101          32768    BLS
      AS_PATH:
```

The **aggregate-address** command configures an aggregate address. The **summary-only** parameter prevents the Layer 3 switch from advertising more specific routes contained within the aggregate route. The **show ip bgp route** command shows that the more specific routes aggregated into 209.1.0.0/16 have been suppressed. In this case, the route to 209.1.44.0/24 has been suppressed. The following command indicates that the route is not being advertised to the Layer 3 switch BGP4 neighbors.

```

Brocade#show ip bgp route 209.1.44.0/24
Number of BGP Routes matching display condition : 1
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
      E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
      Prefix          Next Hop      Metric      LocPrf      Weight Status
1      209.1.44.0/24    10.2.0.1      1           101         32768   BLS
      AS_PATH:
      Route is not advertised to any peers

```

If you want to override the **summary-only** parameter and allow a specific route to be advertised to a neighbor, enter commands such as the following.

```

Brocade(config)#ip prefix-list Unsuppress1 permit 209.1.44.0/24
Brocade(config)#route-map RouteMap1 permit 1
Brocade(config-routemap RouteMap1)#match ip prefix-list Unsuppress1
Brocade(config-routemap RouteMap1)#exit
Brocade(config)#router bgp
Brocade(config-bgp-router)#neighbor 10.1.0.2 unsuppress-map RouteMap1
Brocade(config-bgp-router)#clear ip bgp neighbor 10.1.0.2 soft-out

```

The **ip prefix-list** command configures an IP prefix list for network 209.1.44.0/24, which is the route you want to unsuppress. The next two commands configure a route map that uses the prefix list as input. The **neighbor** command enables the Layer 3 switch to advertise the routes specified in the route map to neighbor 10.1.0.2. The **clear** command performs a soft reset of the session with the neighbor so that the Layer 3 switch can advertise the unsuppressed route.

Syntax: [no] **neighbor** <ip-addr> | <peer-group-name> **unsuppress-map** <map-name>

The following command verifies that the route has been unsuppressed.

```

Brocade#show ip bgp route 209.1.44.0/24
Number of BGP Routes matching display condition : 1
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
      E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
      Prefix          Next Hop      Metric      LocPrf      Weight Status
1      209.1.44.0/24    10.2.0.1      1           101         32768   BLS
      AS_PATH:
      Route is advertised to 1 peers:
      10.1.0.2(4)

```

Displaying and clearing route flap dampening statistics

The software provides many options for displaying and clearing route flap statistics. To display the statistics, use either of the following methods.

Displaying route flap dampening statistics

To display route dampening statistics or all the dampened routes, enter the **show ip bgp flap-statistics** command at any level of the CLI.

Route flap dampening configuration

```
Brocade#show ip bgp flap-statistics
Total number of flapping routes: 414
      Status Code  >:best d:damped h:history *:valid
      Network      From      Flaps Since      Reuse      Path
h> 192.50.206.0/23 166.90.213.77 1      0 :0 :13 0 :0 :0 65001 4355 1 701
h> 203.255.192.0/20 166.90.213.77 1      0 :0 :13 0 :0 :0 65001 4355 1 7018
h> 203.252.165.0/24 166.90.213.77 1      0 :0 :13 0 :0 :0 65001 4355 1 7018
h> 192.50.208.0/23 166.90.213.77 1      0 :0 :13 0 :0 :0 65001 4355 1 701
h> 133.33.0.0/16 166.90.213.77 1      0 :0 :13 0 :0 :0 65001 4355 1 701
*> 204.17.220.0/24 166.90.213.77 1      0 :1 :4 0 :0 :0 65001 4355 701 62
```

Syntax: `show ip bgp flap-statistics [regular-expression <regular-expression> | <address> <mask> [longer-prefixes] | neighbor <ip-addr>]`

The **regular-expression** <regular-expression> parameter is a regular expression. The regular expressions are the same ones supported for BGP4 AS-path filters. Refer to [“Using regular expressions to filter”](#) on page 1397.

The <address> <mask> parameter specifies a particular route. If you also use the optional **longer-prefixes** parameter, then all statistics for routes that match the specified route or have a longer prefix than the specified route are displayed. For example, if you specify **209.157.0.0 longer**, then all routes with the prefix 209.157. or that have a longer prefix (such as 209.157.22.) are displayed.

The **neighbor** <ip-addr> parameter displays route flap dampening statistics only for routes learned from the specified neighbor. You also can display route flap statistics for routes learned from a neighbor by entering the following command: **show ip bgp neighbors <ip-addr> flap-statistics**.

[Table 241](#) shows the field definitions for the display output.

TABLE 241 Route flap dampening statistics

Field	Description
Total number of flapping routes	Total number of routes in the Layer 3 switch BGP4 route table that have changed state and thus have been marked as flapping routes.
Status code	Indicates the dampening status of the route, which can be one of the following: <ul style="list-style-type: none">• > – This is the best route among those in the BGP4 route table to the route destination.• d – This route is currently dampened, and thus unusable.• h – The route has a history of flapping and is unreachable now.• * – The route has a history of flapping but is currently usable.
Network	The destination network of the route.
From	The neighbor that sent the route to the Layer 3 switch.
Flaps	The number of flaps (state changes) the route has experienced.
Since	The amount of time since the first flap of this route.
Reuse	The amount of time remaining until this route will be un-suppressed and thus be usable again.
Path	Shows the AS-path information for the route.

You also can display all the dampened routes by entering the **show ip bgp dampened-paths** command.

Clearing route flap dampening statistics

To clear route flap dampening statistics, use the following CLI method.

NOTE

Clearing the dampening statistics for a route does not change the dampening status of the route.

To clear all the route dampening statistics, enter the following command at any level of the CLI.

```
Brocade#clear ip bgp flap-statistics
```

Syntax: `clear ip bgp flap-statistics` [**regular-expression** <regular-expression> | <address> <mask> | **neighbor** <ip-addr>]

The parameters are the same as those for the **show ip bgp flap-statistics** command (except the **longer-prefixes** option is not supported). Refer to [“Displaying route flap dampening statistics”](#) on page 1419.

NOTE

The **clear ip bgp damping** command not only clears statistics but also un-suppresses the routes. Refer to [“Displaying route flap dampening statistics”](#) on page 1419.

Generating traps for BGP

You can enable and disable SNMP traps for BGP. BGP traps are enabled by default.

To enable BGP traps after they have been disabled, enter the following command.

```
Brocade(config)#snmp-server enable traps bgp
```

Syntax: [**no**] **snmp-server enable traps bgp**

Use the **no** form of the command to disable BGP traps.

Displaying BGP4 information

You can display the following configuration information and statistics for the BGP4 protocol on the router:

- Summary BGP4 configuration information for the router
- Active BGP4 configuration information (the BGP4 information in the running-config)
- CPU utilization statistics
- Neighbor information
- Peer-group information
- Information about the paths from which BGP4 selects routes
- Summary BGP4 route information
- The router BGP4 route table
- Route flap dampening statistics
- Active route maps (the route map configuration information in the running-config)
- BGP4 graceful restart neighbor information

Displaying summary BGP4 information

You can display the local AS number, the maximum number of routes and neighbors supported, and some BGP4 statistics.

To view summary BGP4 information for the router, enter the **show ip bgp summary** command at any CLI prompt.

```
Brocade#show ip bgp summary
BGP4 Summary
Router ID: 101.0.0.1   Local AS Number : 4
Confederation Identifier : not configured
Confederation Peers: 4 5
Maximum Number of Paths Supported for Load Sharing : 1
Number of Neighbors Configured : 11
Number of Routes Installed : 2
Number of Routes Advertising to All Neighbors : 8
Number of Attribute Entries Installed : 6
Neighbor Address  AS#  State  Time      Rt:Accepted  Filtered  Sent  ToSend
1.2.3.4           200  ADMDN  0h44m56s  0            0         0     2
10.0.0.2          5    ADMDN  0h44m56s  0            0         0     0
10.1.0.2          5    ESTAB  0h44m56s  1            11        0     0
10.2.0.2          5    ESTAB  0h44m55s  1            0         0     0
10.3.0.2          5    ADMDN  0h25m28s  0            0         0     0
10.4.0.2          5    ADMDN  0h25m31s  0            0         0     0
10.5.0.2          5    CONN   0h 0m 8s  0            0         0     0
10.7.0.2          5    ADMDN  0h44m56s  0            0         0     0
100.0.0.1         4    ADMDN  0h44m56s  0            0         0     2
102.0.0.1         4    ADMDN  0h44m56s  0            0         0     2
150.150.150.150  0    ADMDN  0h44m56s  0            0         0     2
```

Table 242 lists the field definitions for the command output.

TABLE 242 BGP4 summary information

Field	Description
Router ID	The Layer 3 switch router ID.
Local AS Number	The BGP4 AS number the router is in.
Confederation Identifier	The AS number of the confederation the Layer 3 switch is in.
Confederation Peers	The numbers of the local autonomous systems contained in the confederation. This list matches the confederation peer list you configure on the Layer 3 switch.
Maximum Number of Paths Supported for Load Sharing	The maximum number of route paths across which the device can balance traffic to the same destination. The feature is enabled by default but the default number of paths is 1. You can increase the number from 2 through 4 paths. Refer to “Changing the maximum number of paths for BGP4 load sharing” on page 1366.
Number of Neighbors Configured	The number of BGP4 neighbors configured on this Layer 3 switch.
Number of Routes Installed	The number of BGP4 routes in the router BGP4 route table. To display the BGP4 route table, refer to “Displaying the BGP4 route table” on page 1441.
Number of Routes Advertising to All Neighbors	The total of the RtSent and RtToSend columns for all neighbors.

TABLE 242 BGP4 summary information (Continued)

Field	Description
Number of Attribute Entries Installed	The number of BGP4 route-attribute entries in the router route-attributes table. To display the route-attribute table, refer to “Displaying BGP4 route-attribute entries” on page 1447.
Neighbor Address	The IP addresses of this router BGP4 neighbors.
AS#	The AS number.

TABLE 242 BGP4 summary information (Continued)

Field	Description
State	<p>The state of this router neighbor session with each neighbor. The states are from this router perspective of the session, not the neighbor perspective. The state values are based on the BGP4 state machine values described in RFC 1771 and can be one of the following for each router:</p> <ul style="list-style-type: none"> • IDLE – The BGP4 process is waiting to be started. Usually, enabling BGP4 or establishing a neighbor session starts the BGP4 process. A minus sign (-) indicates that the session has gone down and the software is clearing or removing routes. • ADMND – The neighbor has been administratively shut down. Refer to “Administratively shutting down a session with a BGP4 neighbor” on page 1364. A minus sign (-) indicates that the session has gone down and the software is clearing or removing routes. • CONNECT – BGP4 is waiting for the connection process for the TCP neighbor session to be completed. • ACTIVE – BGP4 is waiting for a TCP connection from the neighbor. <p>NOTE: If the state frequently changes between CONNECT and ACTIVE, there may be a problem with the TCP connection.</p> <ul style="list-style-type: none"> • OPEN SENT – BGP4 is waiting for an Open message from the neighbor. • OPEN CONFIRM – BGP4 has received an OPEN message from the neighbor and is now waiting for either a KEEPALIVE or NOTIFICATION message. If the router receives a KEEPALIVE message from the neighbor, the state changes to Established. If the message is a NOTIFICATION, the state changes to Idle. • ESTABLISHED – BGP4 is ready to exchange UPDATE packets with the neighbor. If there is more BGP data in the TCP receiver queue, a plus sign (+) is also displayed. <p>NOTE: If you display information for the neighbor using the show ip bgp neighbors <ip-addr> command, the TCP receiver queue value will be greater than 0.</p> <p>Operational States: Additional information regarding the BGP operational states described above may be added as follows:</p> <ul style="list-style-type: none"> • (+) – is displayed if there is more BGP4 data in the TCP receiver queue. Note: If you display information for the neighbor using the show ip bgp neighbors <ip-addr> command, the TCP receiver queue value will be greater than 0. • (-) – indicates that the session has gone down and the software is clearing or removing routes. • (*) – indicates that the inbound or outbound policy is being updated for the peer. • (s) – indicates that the peer has negotiated restart, and the session is in a stale state. • (r) – indicates that the peer is restarting the BGP4 connection, through restart. • (^) – on the standby MP indicates that the peer is in the ESTABLISHED state and has received restart capability (in the primary MP). • (<) – indicates that the device is waiting to receive the “End of RIB” message the peer.
Time	The time that has passed since the state last changed.
Accepted	The number of routes received from the neighbor that this router installed in the BGP4 route table. Usually, this number is lower than the RoutesRcvd number. The difference indicates that this router filtered out some of the routes received in the UPDATE messages.

TABLE 242 BGP4 summary information (Continued)

Field	Description
Filtered	The routes or prefixes that have been filtered out: <ul style="list-style-type: none"> • If soft reconfiguration is enabled, this field shows how many routes were filtered out (not placed in the BGP4 route table) but retained in memory. • If soft reconfiguration is not enabled, this field shows the number of BGP4 routes that have been filtered out.
Sent	The number of BGP4 routes that the Layer 3 switch has sent to the neighbor.
ToSend	The number of routes the Layer 3 switch has queued to send to this neighbor.

Displaying the active BGP4 configuration

To view the active BGP4 configuration information contained in the running-config without displaying the entire running-config, use the following CLI method.

To display the device active BGP4 configuration, enter the **show ip bgp config** command at any level of the CLI.

```
Brocade#show ip bgp config
Current BGP configuration:
router bgp
address-filter 1 deny any any
as-path-filter 1 permit ^65001$
local-as 65002
maximum-paths 4
neighbor pgl peer-group
neighbor pgl remote-as 65001
neighbor pgl description "Brocade group 1"
neighbor pgl distribute-list out 1
neighbor 192.169.100.1 peer-group pgl
neighbor 192.169.101.1 peer-group pgl
neighbor 192.169.102.1 peer-group pgl
neighbor 192.169.201.1 remote-as 65101
neighbor 192.169.201.1 shutdown
neighbor 192.169.220.3 remote-as 65432
network 1.1.1.0 255.255.255.0
network 2.2.2.0 255.255.255.0
redistribute connected
```

Syntax: show ip bgp config

Displaying CPU utilization statistics

You can display CPU utilization statistics for BGP4 and other IP protocols.

To display CPU utilization statistics for BGP4 for the previous one-second, one-minute, five-minute, and fifteen-minute intervals, enter the **show process cpu** command at any level of the CLI.

Displaying BGP4 information

```
Brocade#show process cpu
Process Name    5Sec(%)    1Min(%)    5Min(%)    15Min(%)    Runtime(ms)
ARP              0.01        0.03        0.09        0.22         9
BGP            0.04       0.06       0.08       0.14       13
GVRP             0.00        0.00        0.00        0.00         0
ICMP             0.00        0.00        0.00        0.00         0
IP               0.00        0.00        0.00        0.00         0
OSPF             0.00        0.00        0.00        0.00         0
RIP              0.00        0.00        0.00        0.00         0
STP              0.00        0.00        0.00        0.00         0
VRRP             0.00        0.00        0.00        0.00         0
```

If the software has been running less than 15 minutes (the maximum interval for utilization statistics), the command indicates how long the software has been running. Here is an example.

```
Brocade#show process cpu
The system has only been up for 6 seconds.
Process Name    5Sec(%)    1Min(%)    5Min(%)    15Min(%)    Runtime(ms)
ARP              0.01        0.00        0.00        0.00         0
BGP              0.00        0.00        0.00        0.00         0
GVRP             0.00        0.00        0.00        0.00         0
ICMP             0.01        0.00        0.00        0.00         1
IP               0.00        0.00        0.00        0.00         0
OSPF             0.00        0.00        0.00        0.00         0
RIP              0.00        0.00        0.00        0.00         0
STP              0.00        0.00        0.00        0.00         0
VRRP             0.00        0.00        0.00        0.00         0
```

To display utilization statistics for a specific number of seconds, enter a command such as the following.

```
Brocade#show process cpu 2
Statistics for last 1 sec and 80 ms
Process Name    Sec(%)    Time(ms)
ARP              0.00        0
BGP              0.00        0
GVRP             0.00        0
ICMP             0.01        1
IP               0.00        0
OSPF             0.00        0
RIP              0.00        0
STP              0.01        0
VRRP             0.00        0
```

When you specify how many seconds' worth of statistics you want to display, the software selects the sample that most closely matches the number of seconds you specified. In this example, statistics are requested for the previous two seconds. The closest sample available is actually for the previous 1 second plus 80 milliseconds.

Syntax: `show process cpu [<num>]`

The `<num>` parameter specifies the number of seconds and can be from 1 through 900. If you use this parameter, the command lists the usage statistics only for the specified number of seconds. If you do not use this parameter, the command lists the usage statistics for the previous one-second, one-minute, five-minute, and fifteen-minute intervals.

Displaying summary neighbor information

To display summary neighbor information, enter a command such as the following at any level of the CLI.

```
Brocade#show ip bgp neighbors 192.168.4.211 routes-summary
1   IP Address: 192.168.4.211
Routes Accepted/Installed:1,  Filtered/Kept:11,  Filtered:11
    Routes Selected as BEST Routes:1
        BEST Routes not Installed in IP Forwarding Table:0
    Unreachable Routes (no IGP Route for NEXTHop):0
    History Routes:0

NLRI's Received in Update Message:24,  Withdraws:0 (0),  Replacements:1
    NLRI's Discarded due to
        Maximum Prefix Limit:0,  AS Loop:0
        Invalid Nexthop:0,  Invalid Nexthop Address:0.0.0.0
        Duplicated Originator_ID:0,  Cluster_ID:0

Routes Advertised:0,  To be Sent:0,  To be Withdrawn:0
NLRI's Sent in Update Message:0,  Withdraws:0,  Replacements:0

Peer Out of Memory Count for:
    Receiving Update Messages:0,  Accepting Routes(NLRI):0
    Attributes:0,  Outbound Routes(RIB-out):0
```

Syntax: `show ip bgp neighbors [<ip-addr>] | [routes-summary]`

[Table 243](#) lists the field definitions for the command output.

TABLE 243 BGP4 route summary information for a neighbor

Field	Description
IP Address	The IP address of the neighbor
Routes Received	How many routes the Layer 3 switch has received from the neighbor during the current BGP4 session: <ul style="list-style-type: none"> Accepted/Installed – Indicates how many of the received routes the Layer 3 switch accepted and installed in the BGP4 route table. Filtered/Kept – Indicates how many routes were filtered out, but were nonetheless retained in memory for use by the soft reconfiguration feature. Filtered – Indicates how many of the received routes were filtered out.
Routes Selected as BEST Routes	The number of routes that the Layer 3 switch selected as the best routes to their destinations.
BEST Routes not Installed in IP Forwarding Table	The number of routes received from the neighbor that are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the Layer 3 switch received better routes from other sources (such as OSPF, RIP, or static IP routes).
Unreachable Routes	The number of routes received from the neighbor that are unreachable because the Layer 3 switch does not have a valid RIP, OSPF, or static route to the next hop.
History Routes	The number of routes that are down but are being retained for route flap dampening purposes.

TABLE 243 BGP4 route summary information for a neighbor (Continued)

Field	Description
NLRIs Received in Update Message	<p>The number of routes received in Network Layer Reachability (NLRI) format in UPDATE messages:</p> <ul style="list-style-type: none"> Withdraws – The number of withdrawn routes the Layer 3 switch has received. Replacements – The number of replacement routes the Layer 3 switch has received.
NLRIs Discarded due to	<p>Indicates the number of times the Layer 3 switch discarded an NLRI for the neighbor due to the following reasons:</p> <ul style="list-style-type: none"> Maximum Prefix Limit – The Layer 3 switch configured maximum prefix amount had been reached. AS Loop – An AS loop occurred. An AS loop occurs when the BGP4 AS-path attribute contains the local AS number. Invalid Nexthop – The next hop value was not acceptable. Duplicated Originator_ID – The originator ID was the same as the local router ID. Cluster_ID – The cluster list contained the local cluster ID, or contained the local router ID (see above) if the cluster ID is not configured.
Routes Advertised	<p>The number of routes the Layer 3 switch has advertised to this neighbor:</p> <ul style="list-style-type: none"> To be Sent – The number of routes the Layer 3 switch has queued to send to this neighbor. To be Withdrawn – The number of NLRIs for withdrawing routes the Layer 3 switch has queued up to send to this neighbor in UPDATE messages.
NLRIs Sent in Update Message	<p>The number of NLRIs for new routes the Layer 3 switch has sent to this neighbor in UPDATE messages:</p> <ul style="list-style-type: none"> Withdraws – The number of routes the Layer 3 switch has sent to the neighbor to withdraw. Replacements – The number of routes the Layer 3 switch has sent to the neighbor to replace routes the neighbor already has.
Peer Out of Memory Count for	<p>Statistics for the times the Layer 3 switch has run out of BGP4 memory for the neighbor during the current BGP4 session:</p> <ul style="list-style-type: none"> Receiving Update Messages – The number of times UPDATE messages were discarded because there was no memory for attribute entries. Accepting Routes(NLRI) – The number of NLRIs discarded because there was no memory for NLRI entries. This count is not included in the Receiving Update Messages count. Attributes – The number of times there was no memory for BGP4 attribute entries. Outbound Routes(RIB-out) – The number of times there was no memory to place a “best” route into the neighbor's route information base (Adj-RIB-Out) for routes to be advertised.

Displaying BGP4 neighbor information

To view BGP4 neighbor information including the values for all the configured parameters, enter the following command.

NOTE

The display shows all the configured parameters for the neighbor. Only the parameters that have values different from their defaults are shown.

```

Brocade#show ip bgp neighbors 10.4.0.2
1  IP Address: 10.4.0.2, AS: 5 (EBGP), RouterID: 100.0.0.1
    Description: neighbor 10.4.0.2
    State: ESTABLISHED, Time: 0h1m0s, KeepAliveTime: 0, HoldTime: 0
    PeerGroup: pgl

```

This example shows how to display information for a specific neighbor, by specifying the neighbor IP address with the command. None of the other display options are used; thus, all of the information is displayed for the neighbor. The number in the far left column indicates the neighbor for which information is displayed. When you list information for multiple neighbors, this number makes the display easier to read.

The TCP statistics at the end of the display show status for the TCP session with the neighbor. Most of the fields show information stored in the Layer 3 switch Transmission Control Block (TCB) for the TCP session between the Layer 3 switch and its neighbor. These fields are described in detail in section 3.2 of RFC 793, “Transmission Control Protocol Functional Specification”.

Syntax: `show ip bgp neighbors [<ip-addr> [advertised-routes [detail [<ip-addr>[/<mask-bits>]]]] | [attribute-entries [detail]] | [flap-statistics] | [last-packet-with-error] | [received prefix-filter] | [received-routes] | [routes [best]] | [detail [best]] | [not-installed-best] | [unreachable]] | [rib-out-routes [<ip-addr>/<mask-bits> | <ip-addr> <net-mask> | detail]] | [routes-summary]]`

The `<ip-addr>` option lets you narrow the scope of the command to a specific neighbor.

The **advertised-routes** option displays only the routes that the Layer 3 switch has advertised to the neighbor during the current BGP4 neighbor session.

The **attribute-entries** option shows the attribute-entries associated with routes received from the neighbor.

The **flap-statistics** option shows the route flap statistics for routes received from or sent to the neighbor.

The **last-packet-with-error** option displays the last packet from the neighbor that contained an error. The packet's contents are displayed in decoded (human-readable) format.

The **received prefix-filter** option shows the Outbound Route Filters (ORFs) received from the neighbor. This option applies to cooperative route filtering.

The **received-routes** option lists all the route information received in route updates from the neighbor since the soft reconfiguration feature was enabled. Refer to [“Using soft reconfiguration”](#) on page 1452.

The **routes** option lists the routes received in UPDATE messages from the neighbor. You can specify the following additional options:

- **best** – Displays the routes received from the neighbor that the Layer 3 switch selected as the best routes to their destinations.
- **not-installed-best** – Displays the routes received from the neighbor that are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the Layer 3 switch received better routes from other sources (such as OSPF, RIP, or static IP routes).
- **unreachable** – Displays the routes that are unreachable because the Layer 3 switch does not have a valid RIP, OSPF, or static route to the next hop.
- **detail** – Displays detailed information for the specified routes. You can refine your information request by also specifying one of the options above (**best**, **not-installed-best**, or **unreachable**).

The **rib-out-routes** option lists the route information base (RIB) for outbound routes. You can display all the routes or specify a network address.

The **routes-summary** option displays a summary of the following information:

- Number of routes received from the neighbor
- Number of routes accepted by this Layer 3 switch from the neighbor
- Number of routes this Layer 3 switch filtered out of the UPDATES received from the neighbor and did not accept
- Number of routes advertised to the neighbor
- Number of attribute entries associated with routes received from or advertised to the neighbor.

[Table 244](#) lists the field definitions for the command output.

TABLE 244 BGP4 neighbor information

Field	Description
IP Address	The IP address of the neighbor.
AS	The AS the neighbor is in.
EBGP/IBGP	Whether the neighbor session is an IBGP session, an EBGP session, or a confederation EBGP session: <ul style="list-style-type: none"> • EBGP – The neighbor is in another AS. • EBGP_Confed – The neighbor is a member of another sub-AS in the same confederation. • IBGP – The neighbor is in the same AS.

TABLE 244 BGP4 neighbor information (Continued)

Field	Description
RouterID	The neighbor router ID.
Description	The description you gave the neighbor when you configured it on the Layer 3 switch.
State	<p>The state of the router session with the neighbor. The states are from this router perspective of the session, not the neighbor perspective. The state values are based on the BGP4 state machine values described in RFC 1771 and can be one of the following for each router:</p> <ul style="list-style-type: none"> • IDLE – The BGP4 process is waiting to be started. Usually, enabling BGP4 or establishing a neighbor session starts the BGP4 process. A minus sign (-) indicates that the session has gone down and the software is clearing or removing routes. • ADMND – The neighbor has been administratively shut down. Refer to “Administratively shutting down a session with a BGP4 neighbor” on page 1364. A minus sign (-) indicates that the session has gone down and the software is clearing or removing routes. • CONNECT – BGP4 is waiting for the connection process for the TCP neighbor session to be completed. • ACTIVE – BGP4 is waiting for a TCP connection from the neighbor. <p>NOTE: If the state frequently changes between CONNECT and ACTIVE, there may be a problem with the TCP connection.</p> <ul style="list-style-type: none"> • OPEN SENT – BGP4 is waiting for an Open message from the neighbor. • OPEN CONFIRM – BGP4 has received an OPEN message from the neighbor and is now waiting for either a KEEPALIVE or NOTIFICATION message. If the router receives a KEEPALIVE message from the neighbor, the state changes to Established. If the message is a NOTIFICATION, the state changes to Idle. • ESTABLISHED – BGP4 is ready to exchange UPDATE messages with the neighbor. If there is more BGP data in the TCP receiver queue, a plus sign (+) is also displayed. <p>NOTE: If you display information for the neighbor using the show ip bgp neighbors <ip-addr> command, the TCP receiver queue value will be greater than 0.</p>
Time	The amount of time this session has been in its current state.
KeepAliveTime	The keep alive time, which specifies how often this router sends keep alive messages to the neighbor. Refer to “Changing the Keep Alive Time and Hold Time” on page 1365.
HoldTime	The hold time, which specifies how many seconds the router will wait for a KEEPALIVE or UPDATE message from a BGP4 neighbor before deciding that the neighbor is dead. Refer to “Changing the Keep Alive Time and Hold Time” on page 1365.
PeerGroup	The name of the peer group the neighbor is in, if applicable.
Multihop-EBGP	Whether this option is enabled for the neighbor.
RouteReflectorClient	Whether this option is enabled for the neighbor.
SendCommunity	Whether this option is enabled for the neighbor.
NextHopSelf	Whether this option is enabled for the neighbor.
DefaultOriginate	Whether this option is enabled for the neighbor.
MaximumPrefixLimit	Lists the maximum number of prefixes the Layer 3 switch will accept from this neighbor.

TABLE 244 BGP4 neighbor information (Continued)

Field	Description
RemovePrivateAs	Whether this option is enabled for the neighbor.
RefreshCapability	Whether this Layer 3 switch has received confirmation from the neighbor that the neighbor supports the dynamic refresh capability.
CooperativeFilteringCapability	Whether the neighbor is enabled for cooperative route filtering.
Distribute-list	Lists the distribute list parameters, if configured.
Filter-list	Lists the filter list parameters, if configured.
Prefix-list	Lists the prefix list parameters, if configured.
Route-map	Lists the route map parameters, if configured.
Messages Sent	The number of messages this router has sent to the neighbor. The display shows statistics for the following message types: <ul style="list-style-type: none"> • Open • Update • KeepAlive • Notification • Refresh-Req
Messages Received	The number of messages this router has received from the neighbor. The message types are the same as for the Message Sent field.
Last Update Time	Lists the last time updates were sent and received for the following: <ul style="list-style-type: none"> • NLRIs • Withdraws

TABLE 244 BGP4 neighbor information (Continued)

Field	Description
Last Connection Reset Reason	<p>The reason the previous session with this neighbor ended. The reason can be one of the following.</p> <p>Reasons described in the BGP specifications:</p> <ul style="list-style-type: none"> • Message Header Error • Connection Not Synchronized • Bad Message Length • Bad Message Type • OPEN Message Error • Unsupported Version Number • Bad Peer AS Number • Bad BGP Identifier • Unsupported Optional Parameter • Authentication Failure • Unacceptable Hold Time • Unsupported Capability • UPDATE Message Error • Malformed Attribute List • Unrecognized Well-known Attribute • Missing Well-known Attribute • Attribute Flags Error • Attribute Length Error • Invalid ORIGIN Attribute • Invalid NEXT_HOP Attribute • Optional Attribute Error • Invalid Network Field • Malformed AS_PATH • Hold Timer Expired • Finite State Machine Error • Rcv Notification
Last Connection Reset Reason (cont.)	<p>Reasons specific to the Brocade implementation:</p> <ul style="list-style-type: none"> • Reset All Peer Sessions • User Reset Peer Session • Port State Down • Peer Removed • Peer Shutdown • Peer AS Number Change • Peer AS Confederation Change • TCP Connection KeepAlive Timeout • TCP Connection Closed by Remote • TCP Data Stream Error Detected

TABLE 244 BGP4 neighbor information (Continued)

Field	Description
Notification Sent	<p>If the router receives a NOTIFICATION message from the neighbor, the message contains an error code corresponding to one of the following errors. Some errors have subcodes that clarify the reason for the error. Where applicable, the subcode messages are listed underneath the error code messages.</p> <p>Message Header Error:</p> <ul style="list-style-type: none"> • Connection Not Synchronized • Bad Message Length • Bad Message Type • Unspecified <p>Open Message Error:</p> <ul style="list-style-type: none"> • Unsupported Version • Bad Peer As • Bad BGP Identifier • Unsupported Optional Parameter • Authentication Failure • Unacceptable Hold Time • Unspecified <p>Update Message Error:</p> <ul style="list-style-type: none"> • Malformed Attribute List • Unrecognized Attribute • Missing Attribute • Attribute Flag Error • Attribute Length Error • Invalid Origin Attribute • Invalid NextHop Attribute • Optional Attribute Error • Invalid Network Field • Malformed AS Path • Unspecified <p>Hold Timer Expired</p> <p>Finite State Machine Error</p> <p>Cease</p> <p>Unspecified</p>
Notification Received	See above.

TABLE 244 BGP4 neighbor information (Continued)

Field	Description
TCP Connection state	<p>The state of the connection with the neighbor. The connection can have one of the following states:</p> <ul style="list-style-type: none"> • LISTEN – Waiting for a connection request. • SYN-SENT – Waiting for a matching connection request after having sent a connection request. • SYN-RECEIVED – Waiting for a confirming connection request acknowledgment after having both received and sent a connection request. • ESTABLISHED – Data can be sent and received over the connection. This is the normal operational state of the connection. • FIN-WAIT-1 – Waiting for a connection termination request from the remote TCP, or an acknowledgment of the connection termination request previously sent. • FIN-WAIT-2 – Waiting for a connection termination request from the remote TCP. • CLOSE-WAIT – Waiting for a connection termination request from the local user. • CLOSING – Waiting for a connection termination request acknowledgment from the remote TCP. • LAST-ACK – Waiting for an acknowledgment of the connection termination request previously sent to the remote TCP (which includes an acknowledgment of its connection termination request). • TIME-WAIT – Waiting for enough time to pass to be sure the remote TCP received the acknowledgment of its connection termination request. • CLOSED – There is no connection state.
Byte Sent	The number of bytes sent.
Byte Received	The number of bytes received.
Local host	The IP address of the Layer 3 switch.
Local port	The TCP port the Layer 3 switch is using for the BGP4 TCP session with the neighbor.
Remote host	The IP address of the neighbor.
Remote port	The TCP port the neighbor is using for the BGP4 TCP session with the Layer 3 switch.
ISentSeq	The initial send sequence number for the session.
SendNext	The next sequence number to be sent.
TotUnAck	The number of sequence numbers sent by the Layer 3 switch that have not been acknowledged by the neighbor.
TotSent	The number of sequence numbers sent to the neighbor.
ReTrans	The number of sequence numbers that the Layer 3 switch retransmitted because they were not acknowledged.
UnAckSeq	The current acknowledged sequence number.
IRcvSeq	The initial receive sequence number for the session.
RcvNext	The next sequence number expected from the neighbor.
SendWnd	The size of the send window.
TotalRcv	The number of sequence numbers received from the neighbor.
DupliRcv	The number of duplicate sequence numbers received from the neighbor.

TABLE 244 BGP4 neighbor information (Continued)

Field	Description
RcvWnd	The size of the receive window.
SendQue	The number of sequence numbers in the send queue.
RcvQue	The number of sequence numbers in the receive queue.
CngstWnd	The number of times the window has changed.

Displaying route information for a neighbor

You can display routes based on the following criteria:

- A summary of the routes for a specific neighbor.
- The routes received from the neighbor that the Layer 3 switch selected as the best routes to their destinations.
- The routes received from the neighbor that are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the Layer 3 switch received better routes from other sources (such as OSPF, RIP, or static IP routes).
- The routes that are unreachable because the Layer 3 switch does not have a valid RIP, OSPF, or static route to the next hop.
- Routes for a specific network advertised by the Layer 3 switch to the neighbor.
- The Routing Information Base (RIB) for a specific network advertised to the neighbor. You can display the RIB regardless of whether the Layer 3 switch has already sent it to the neighbor.

To display route information for a neighbor, use the following CLI methods.

Displaying summary route information

To display summary route information, enter a command such as the following at any level of the CLI.

```
Brocade#show ip bgp neighbors 10.1.0.2 routes-summary
1  IP Address: 10.1.0.2
Routes Accepted/Installed:1,  Filtered/Kept:11,  Filtered:11
  Routes Selected as BEST Routes:1
    BEST Routes not Installed in IP Forwarding Table:0
  Unreachable Routes (no IGP Route for NEXTHOP):0
  History Routes:0

NLRI's Received in Update Message:24,  Withdraws:0 (0),  Replacements:1
  NLRI's Discarded due to
    Maximum Prefix Limit:0,  AS Loop:0
    Invalid Nexthop:0,  Invalid Nexthop Address:0.0.0.0
    Duplicated Originator_ID:0,  Cluster_ID:0

Routes Advertised:0,  To be Sent:0,  To be Withdrawn:0
NLRI's Sent in Update Message:0,  Withdraws:0,  Replacements:0

Peer Out of Memory Count for:
  Receiving Update Messages:0,  Accepting Routes(NLRI):0
  Attributes:0,  Outbound Routes(RIB-out):0
```

Table 245 lists the field definitions for the command output.

TABLE 245 BGP4 route summary information for a neighbor

Field	Description
Routes Received	How many routes the Layer 3 switch has received from the neighbor during the current BGP4 session: <ul style="list-style-type: none"> • Accepted/Installed – Indicates how many of the received routes the Layer 3 switch accepted and installed in the BGP4 route table. • Filtered – Indicates how many of the received routes the Layer 3 switch did not accept or install because they were denied by filters on the Layer 3 switch.
Routes Selected as BEST Routes	The number of routes that the Layer 3 switch selected as the best routes to their destinations.
BEST Routes not Installed in IP Forwarding Table	The number of routes received from the neighbor that are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the Layer 3 switch received better routes from other sources (such as OSPF, RIP, or static IP routes).
Unreachable Routes	The number of routes received from the neighbor that are unreachable because the Layer 3 switch does not have a valid RIP, OSPF, or static route to the next hop.
History Routes	The number of routes that are down but are being retained for route flap dampening purposes.
NLRIs Received in Update Message	The number of routes received in Network Layer Reachability (NLRI) format in UPDATE messages: <ul style="list-style-type: none"> • Withdraws – The number of withdrawn routes the Layer 3 switch has received. • Replacements – The number of replacement routes the Layer 3 switch has received.
NLRIs Discarded due to	Indicates the number of times the Layer 3 switch discarded an NLRI for the neighbor due to the following reasons: <ul style="list-style-type: none"> • Maximum Prefix Limit – The Layer 3 switch configured maximum prefix amount had been reached. • AS Loop – An AS loop occurred. An AS loop occurs when the BGP4 AS-path attribute contains the local AS number. • Invalid Nexthop – The next hop value was not acceptable. • Duplicated Originator_ID – The originator ID was the same as the local router ID. • Cluster_ID – The cluster list contained the local cluster ID, or contained the local router ID (see above) if the cluster ID is not configured.
Routes Advertised	The number of routes the Layer 3 switch has advertised to this neighbor: <ul style="list-style-type: none"> • To be Sent – The number of routes the Layer 3 switch has queued to send to this neighbor. • To be Withdrawn – The number of NLRIs for withdrawing routes the Layer 3 switch has queued up to send to this neighbor in UPDATE messages.

TABLE 245 BGP4 route summary information for a neighbor (Continued)

Field	Description
NLRIs Sent in Update Message	<p>The number of NLRIs for new routes the Layer 3 switch has sent to this neighbor in UPDATE messages:</p> <ul style="list-style-type: none"> • Withdraws – The number of routes the Layer 3 switch has sent to the neighbor to withdraw. • Replacements – The number of routes the Layer 3 switch has sent to the neighbor to replace routes the neighbor already has.
Peer Out of Memory Count for	<p>Statistics for the times the Layer 3 switch has run out of BGP4 memory for the neighbor during the current BGP4 session:</p> <ul style="list-style-type: none"> • Receiving Update Messages – The number of times UPDATE messages were discarded because there was no memory for attribute entries. • Accepting Routes(NLRI) – The number of NLRIs discarded because there was no memory for NLRI entries. This count is not included in the Receiving Update Messages count. • Attributes – The number of times there was no memory for BGP4 attribute entries. • Outbound Routes(RIB-out) – The number of times there was no memory to place a “best” route into the neighbor's route information base (Adj-RIB-Out) for routes to be advertised.

Displaying advertised routes

To display the routes the Layer 3 switch has advertised to a specific neighbor for a specific network, enter a command such as the following at any level of the CLI.

```
Brocade#show ip bgp neighbors 192.168.4.211 advertised-routes
      There are 2 routes advertised to neighbor 192.168.4.211
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST I:IBGP L:LOCAL
      Network      Next Hop      Metric      LocPrf      Weight      Status
1       102.0.0.0/24  192.168.2.102    12                32768      BL
2       200.1.1.0/24  192.168.2.102     0                32768      BL
```

You also can enter a specific route, as in the following example.

```
Brocade#show ip bgp neighbors 192.168.4.211 advertised 200.1.1.0/24
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST I:IBGP L:LOCAL
      Network      Next Hop      Metric      LocPrf      Weight      Status
1       200.1.1.0/24  192.168.2.102     0                32768      BL
```

Syntax: `show ip bgp neighbors <ip-addr> advertised-routes [<ip-addr>/<prefix>]`

For information about the fields in this display, refer to [Table 247](#) on page 1444. The fields in this display also appear in the `show ip bgp` display.

Displaying the best routes

To display the routes received from a specific neighbor that are the “best” routes to their destinations, enter a command such as the following at any level of the CLI.

```
Brocade#show ip bgp neighbors 192.168.4.211 routes best
```

Syntax: `show ip bgp neighbors <ip-addr> routes best`

For information about the fields in this display, refer to [Table 247](#) on page 1444. The fields in this display also appear in the `show ip bgp` display.

Displaying the best routes that were nonetheless not installed in the IP route table

To display the BGP4 routes received from a specific neighbor that are the “best” routes to their destinations but are not installed in the Layer 3 switch IP route table, enter a command such as the following at any level of the CLI.

```
Brocade#show ip bgp neighbors 192.168.4.211 routes not-installed-best
```

Each of the displayed routes is a valid path to its destination, but the Layer 3 switch received another path from a different source (such as OSPF, RIP, or a static route) that has a lower administrative distance. The Layer 3 switch always selects the path with the lowest administrative distance to install in the IP route table.

Syntax: `show ip bgp neighbors <ip-addr> routes not-installed-best`

For information about the fields in this display, refer to [Table 247](#) on page 1444. The fields in this display also appear in the `show ip bgp` display.

Displaying the routes whose destinations are unreachable

To display BGP4 routes whose destinations are unreachable using any of the BGP4 paths in the BGP4 route table, enter a command such as the following at any level of the CLI.

```
Brocade#show ip bgp neighbors 192.168.4.211 routes unreachable
```

Syntax: `show ip bgp neighbors <ip-addr> routes unreachable`

For information about the fields in this display, refer to [Table 247](#) on page 1444. The fields in this display also appear in the `show ip bgp` display.

Displaying the Adj-RIB-Out for a neighbor

To display the Layer 3 switch current BGP4 Routing Information Base (Adj-RIB-Out) for a specific neighbor and a specific destination network, enter a command such as the following at any level of the CLI.

```
Brocade#show ip bgp neighbors 192.168.4.211 rib-out-routes 192.168.1.0/24
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST I:IBGP L:LOCAL
      Prefix      Next Hop      Metric      LocPrf      Weight Status
1      200.1.1.0/24      0.0.0.0          0          101      32768 BL
```

The Adj-RIB-Out contains the routes that the Layer 3 switch either has most recently sent to the neighbor or is about to send to the neighbor.

Syntax: `show ip bgp neighbors <ip-addr> rib-out-routes [<ip-addr>/<prefix>]`

For information about the fields in this display, refer to [Table 247](#) on page 1444. The fields in this display also appear in the `show ip bgp` display.

Displaying peer group information

You can display configuration information for peer groups.

To display peer-group information, enter a command such as the following at the Privileged EXEC level of the CLI.

```
Brocade#show ip bgp peer-group pg1
1  BGP peer-group is pg
   Description: peer group abc
       SendCommunity: yes
       NextHopSelf: yes
       DefaultOriginate: yes
   Members:
       IP Address: 192.168.10.10, AS: 65111
```

Syntax: `show ip bgp peer-group [<peer-group-name>]`

Only the parameters that have values different from their defaults are listed.

Displaying summary route information

To display summary statistics for all the routes in the Layer 3 switch BGP4 route table, enter a command such as the following at any level of the CLI.

```
Brocade#show ip bgp routes summary
Total number of BGP routes (NLRIs) Installed      : 20
Distinct BGP destination networks                 : 20
Filtered BGP routes for soft reconfig              : 100178
Routes originated by this router                   : 2
Routes selected as BEST routes                    : 19
BEST routes not installed in IP forwarding table   : 1
Unreachable routes (no IGP route for NEXTHOP)     : 1
IBGP routes selected as best routes                : 0
EBGP routes selected as best routes                : 17
```

Syntax: `show ip bgp routes summary`

[Table 246](#) lists the field definitions for the command output.

TABLE 246 BGP4 summary route information

Field	Description
Total number of BGP routes (NLRIs) Installed	The number of BGP4 routes the Layer 3 switch has installed in the BGP4 route table.
Distinct BGP destination networks	The number of destination networks the installed routes represent. The BGP4 route table can have multiple routes to the same network.
Filtered BGP routes for soft reconfig	The number of route updates received from soft-reconfigured neighbors or peer groups that have been filtered out but retained. For information about soft reconfiguration, refer to “Using soft reconfiguration” on page 1452.
Routes originated by this router	The number of routes in the BGP4 route table that this Layer 3 switch originated.
Routes selected as BEST routes	The number of routes in the BGP4 route table that this Layer 3 switch has selected as the best routes to the destinations.
BEST routes not installed in IP forwarding table	The number of BGP4 routes that are the best BGP4 routes to their destinations but were not installed in the IP route table because the Layer 3 switch received better routes from other sources (such as OSPF, RIP, or static IP routes).
Unreachable routes (no IGP route for NEXTHOP)	The number of routes in the BGP4 route table whose destinations are unreachable because the next hop is unreachable.

TABLE 246 BGP4 summary route information (Continued)

Field	Description
IBGP routes selected as best routes	The number of “best” routes in the BGP4 route table that are IBGP routes.
EBGP routes selected as best routes	The number of “best” routes in the BGP4 route table that are EBGP routes.

Displaying the BGP4 route table

BGP4 uses filters you define as well as the algorithm described in [“How BGP4 selects a path for a route”](#) on page 1344 to determine the preferred route to a destination. BGP4 sends only the preferred route to the router IP table. However, if you want to view all the routes BGP4 knows about, you can display the BGP4 table using either of the following methods.

To view the BGP4 route table, enter the following command.

```
Brocade#show ip bgp routes
Total number of BGP Routes: 97371
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
      E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED
      Prefix          Next Hop      Metric      LocPrf      Weight      Status
1      3.0.0.0/8       192.168.4.106      100          0          BE
      AS_PATH: 65001 4355 701 80
2      4.0.0.0/8       192.168.4.106      100          0          BE
      AS_PATH: 65001 4355 1
3      4.60.212.0/22    192.168.4.106      100          0          BE
      AS_PATH: 65001 4355 701 1 189
4      6.0.0.0/8       192.168.4.106      100          0          BE
      AS_PATH: 65001 4355 3356 7170 1455
5      8.8.1.0/24      192.168.4.106      0            100         0          BE
      AS_PATH: 65001
```

Syntax: `show ip bgp routes` `[[network] <ip-addr>]` `<num>` `[age <secs>]` `[as-path-access-list <num>]` `[best]` `[cidr-only]` `[community <num>]` `[no-export]` `[no-advertise]` `[internet]` `[local-as]` `[community-access-list <num>]` `[community-list <num>]` `[detail <option>]` `[filter-list <num, num,...>]` `[next-hop <ip-addr>]` `[no-best]` `[not-installed-best]` `[prefix-list <string>]` `[regular-expression <regular-expression>]` `[route-map <map-name>]` `[summary]` `[unreachable]`

The `<ip-addr>` option displays routes for a specific network. The **network** keyword is optional. You can enter the network address without entering “network” in front of it.

The `<num>` option specifies the table entry with which you want the display to start. For example, if you want to list entries beginning with table entry 100, specify 100.

The **age** `<secs>` parameter displays only the routes that have been received or updated more recently than the number of seconds you specify.

The **as-path-access-list** `<num>` parameter filters the display using the specified AS-path ACL.

The **best** parameter displays the routes received from the neighbor that the Layer 3 switch selected as the best routes to their destinations.

The **cidr-only** option lists only the routes whose network masks do not match their class network length.

The **community** option lets you display routes for a specific community. You can specify **local-as**, **no-export**, **no-advertise**, **internet**, or a private community number. You can specify the community number as either two five-digit integer values of 1 through 65535, separated by a colon (for example, 12345:6789) or a single long integer value.

The **community-access-list** *<num>* parameter filters the display using the specified community ACL.

The **community-list** option lets you display routes that match a specific community filter.

The **detail** option lets you display more details about the routes. You can refine your request by also specifying one of the other display options after the detail keyword.

The **filter-list** option displays routes that match a specific address filter list.

The **next-hop** *<ip-addr>* option displays the routes for a given next-hop IP address.

The **no-best** option displays the routes for which none of the routes to a given prefix were selected as the best route. The IP route table does not contain a BGP4 route for any of the routes listed by the command.

The **not-installed-best** option displays the routes received from the neighbor that are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the Layer 3 switch received better routes from other sources (such as OSPF, RIP, or static IP routes).

The **prefix-list** *<string>* parameter filters the display using the specified IP prefix list.

The **regular-expression** *<regular-expression>* option filters the display based on a regular expression. Refer to [“Using regular expressions to filter”](#) on page 1397.

The **route-map** *<map-name>* parameter filters the display using the specified route map. The software displays only the routes that match the match statements in the route map. The software disregards the route map set statements.

The **summary** option displays summary information for the routes.

The **unreachable** option displays the routes that are unreachable because the Layer 3 switch does not have a valid RIP, OSPF, or static route to the next hop.

Displaying the best BGP4 routes

To display all the BGP4 routes in the Layer 3 switch BGP4 route table that are the best routes to their destinations, enter a command such as the following at any level of the CLI.

```
Brocade#show ip bgp routes best
Searching for matching routes, use ^C to quit...
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
      E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
      Prefix           Next Hop           Metric      LocPrf      Weight Status
1      3.0.0.0/8        192.168.4.106           100          0          BE
      AS_PATH: 65001 4355 701 80
2      4.0.0.0/8        192.168.4.106           100          0          BE
      AS_PATH: 65001 4355 1
3      4.60.212.0/22     192.168.4.106           100          0          BE
      AS_PATH: 65001 4355 701 1 189
4      6.0.0.0/8        192.168.4.106           100          0          BE
      AS_PATH: 65001 4355 3356 7170 1455
5      9.2.0.0/16       192.168.4.106           100          0          BE
      AS_PATH: 65001 4355 701
```

Syntax: show ip bgp routes best

For information about the fields in this display, refer to [Table 247](#) on page 1444. The fields in this display also appear in the **show ip bgp** display.

Displaying the best BGP4 routes that are not in the IP route table

When the Layer 3 switch has multiple routes to a destination from different sources (such as BGP4, OSPF, RIP, or static routes), the Layer 3 switch selects the route with the lowest administrative distance as the best route, and installs that route in the IP route table.

To display the BGP4 routes that are the “best” routes to their destinations but are not installed in the Layer 3 switch IP route table, enter a command such as the following at any level of the CLI.

```
Brocade#show ip bgp routes not-installed-best
Searching for matching routes, use ^C to quit...
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
        E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
        Prefix          Next Hop          Metric      LocPrf      Weight Status
1          192.168.4.0/24  192.168.4.106    0           100         0      bE
        AS_PATH: 65001
```

Each of the displayed routes is a valid path to its destination, but the Layer 3 switch received another path from a different source (such as OSPF, RIP, or a static route) that has a lower administrative distance. The Layer 3 switch always selects the path with the lowest administrative distance to install in the IP route table.

Notice that the route status in this example is the new status, “b”. Refer to [Table 247](#) on page 1444 for a description.

Syntax: show ip bgp routes not-installed-best

For information about the fields in this display, refer to [Table 247](#) on page 1444. The fields in this display also appear in the **show ip bgp** display.

NOTE

To display the routes that the Layer 3 switch has selected as the best routes and installed in the IP route table, display the IP route table using the **show ip route** command.

Displaying BGP4 routes whose destinations are unreachable

To display BGP4 routes whose destinations are unreachable using any of the BGP4 paths in the BGP4 route table, enter a command such as the following at any level of the CLI.

```
Brocade#show ip bgp routes unreachable
Searching for matching routes, use ^C to quit...
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
        H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED
        Prefix          Next Hop          Metric      LocPrf      Weight Status
1          8.8.8.0/24  192.168.5.1      0           101         0
        AS_PATH: 65001 4355 1
```

Syntax: show ip bgp routes unreachable

For information about the fields in this display, refer to [Table 247](#) on page 1444. The fields in this display also appear in the **show ip bgp** display.

Displaying information for a specific route

To display BGP4 network information by specifying an IP address within the network, enter a command such as the following at any level of the CLI.

```
Brocade#show ip bgp 9.3.4.0
Number of BGP Routes matching display condition : 1
Status codes: s suppressed, d damped, h history, * valid, > best, i internal
Origin codes: i - IGP, e - EGP, ? - incomplete
      Network      Next Hop      Metric LocPrf Weight Path
*>  9.3.4.0/24      192.168.4.106      100    0      65001 4355 1 1221 ?
      Last update to IP routing table: 0h11m38s, 1 path(s) installed:
      Gateway      Port
      192.168.2.1      2/1
      Route is advertised to 1 peers:
      20.20.20.2(65300)
```

Syntax: `show ip bgp [route] <ip-addr>/<prefix> [longer-prefixes] | <ip-addr>`

If you use the **route** option, the display for the information is different, as shown in the following example.

```
Brocade#show ip bgp route 9.3.4.0
Number of BGP Routes matching display condition : 1
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
      E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
      Prefix      Next Hop      Metric      LocPrf      Weight Status
1      9.3.4.0/24      192.168.4.106      100          0          BE
      AS_PATH: 65001 4355 1 1221
      Last update to IP routing table: 0h12m1s, 1 path(s) installed:
      Gateway      Port
      192.168.2.1      2/1
      Route is advertised to 1 peers:
      20.20.20.2(65300)
```

These displays show the following information.

TABLE 247 BGP4 network information

Field	Description
Number of BGP Routes matching display condition	The number of routes that matched the display parameters you entered. This is the number of routes displayed by the command.
Status codes	A list of the characters the display uses to indicate the route status. The status code appears in the left column of the display, to the left of each route. The status codes are described in the command output. NOTE: This field appears only if you <i>do not</i> enter the route option.
Prefix	The network address and prefix.
Next Hop	The next-hop router for reaching the network from the Layer 3 switch.
Metric	The value of the route MED attribute. If the route does not have a metric, this field is blank.
LocPrf	The degree of preference for this route relative to other routes in the local AS. When the BGP4 algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen. The preference can have a value from 0 through 4294967295.

TABLE 247 BGP4 network information (Continued)

Field	Description
Weight	The value that this router associates with routes from a specific neighbor. For example, if the router receives routes to the same destination from two BGP4 neighbors, the router prefers the route from the neighbor with the larger weight.
Path	The route AS path. NOTE: This field appears only if you <i>do not</i> enter the route option.
Origin code	A character the display uses to indicate the route origin. The origin code appears to the right of the AS path (Path field). The origin codes are described in the command output. NOTE: This field appears only if you <i>do not</i> enter the route option.
Status	<p>The route status, which can be one or more of the following:</p> <ul style="list-style-type: none"> • A – AGGREGATE. The route is an aggregate route for multiple networks. • B – BEST. BGP4 has determined that this is the optimal route to the destination. <p>NOTE: If the “b” is shown in lowercase, the software was not able to install the route in the IP route table.</p> <ul style="list-style-type: none"> • b – NOT-INSTALLED-BEST. The routes received from the neighbor are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the Layer 3 switch received better routes from other sources (such as OSPF, RIP, or static IP routes). • C – CONFED_EBGP. The route was learned from a neighbor in the same confederation and AS, but in a different sub-AS within the confederation. • D – DAMPED. This route has been dampened (by the route dampening feature), and is currently unusable. • H – HISTORY. Route dampening is configured for this route, and the route has a history of flapping and is unreachable now. • I – INTERNAL. The route was learned through BGP4. • L – LOCAL. The route originated on this Layer 3 switch. • M – MULTIPATH. BGP4 load sharing is enabled and this route was selected as one of the best ones to the destination. The best route among the multiple paths also is marked with “B”. <p>NOTE: If the “m” is shown in lowercase, the software was not able to install the route in the IP route table.</p> <ul style="list-style-type: none"> • S – SUPPRESSED. This route was suppressed during aggregation and thus is not advertised to neighbors. <p>NOTE: This field appears only if you enter the route option.</p>

Displaying route details

Here is an example of the information displayed when you use the **detail** option. In this example, the information for one route is shown.

```

Brocade#show ip bgp routes detail
Total number of BGP Routes: 2
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED
1 Prefix: 10.5.0.0/24, Status: BME, Age: 0h28m28s
NEXT_HOP: 201.1.1.2, Learned from Peer: 10.1.0.2 (5)
LOCAL_PREF: 101, MED: 0, ORIGIN: igp, Weight: 10
AS_PATH: 5
Adj_RIB_out count: 4, Admin distance 20

```

These displays show the following information.

TABLE 248 BGP4 route information

Field	Description
Total number of BGP Routes	The number of BGP4 routes.
Status codes	A list of the characters the display uses to indicate the route status. The status code is appears in the left column of the display, to the left of each route. The status codes are described in the command output.
Prefix	The network prefix and mask length.
Status	<p>The route status, which can be one or more of the following:</p> <ul style="list-style-type: none"> • A – AGGREGATE. The route is an aggregate route for multiple networks. • B – BEST. BGP4 has determined that this is the optimal route to the destination. <p>NOTE: If the “b” is shown in lowercase, the software was not able to install the route in the IP route table.</p> <ul style="list-style-type: none"> • b – NOT-INSTALLED-BEST. The routes received from the neighbor are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the Layer 3 switch received better routes from other sources (such as OSPF, RIP, or static IP routes). • C – CONFED_EBGP. The route was learned from a neighbor in the same confederation and AS, but in a different sub-AS within the confederation. • D – DAMPED. This route has been dampened (by the route dampening feature), and is currently unusable. • H – HISTORY. Route dampening is configured for this route, and the route has a history of flapping and is unreachable now. • I – INTERNAL. The route was learned through BGP4. • L – LOCAL. The route originated on this Layer 3 switch. • M – MULTIPATH. BGP4 load sharing is enabled and this route was selected as one of the best ones to the destination. The best route among the multiple paths also is marked with “B”. <p>NOTE: If the “m” is shown in lowercase, the software was not able to install the route in the IP route table.</p> <ul style="list-style-type: none"> • S – SUPPRESSED. This route was suppressed during aggregation and thus is not advertised to neighbors.
Age	The last time an update occurred.
Next_Hop	The next-hop router for reaching the network from the Layer 3 switch.
Learned from Peer	The IP address of the neighbor that sent this route.
Local_Pref	The degree of preference for this route relative to other routes in the local AS. When the BGP4 algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen. The preference can have a value from 0 through 4294967295.
MED	The route metric. If the route does not have a metric, this field is blank.
Origin	<p>The source of the route information. The origin can be one of the following:</p> <ul style="list-style-type: none"> • EGP – The routes with this set of attributes came to BGP through EGP. • IGP – The routes with this set of attributes came to BGP through IGP. • INCOMPLETE – The routes came from an origin other than one of the above. For example, they may have been redistributed from OSPF or RIP. <p>When BGP4 compares multiple routes to a destination to select the best route, IGP is preferred over EGP and both are preferred over INCOMPLETE.</p>

TABLE 248 BGP4 route information (Continued)

Field	Description
Weight	The value that this router associates with routes from a specific neighbor. For example, if the router receives routes to the same destination from two BGP4 neighbors, the router prefers the route from the neighbor with the larger weight.
Atomic	Whether network information in this route has been aggregated <i>and</i> this aggregation has resulted in information loss. NOTE: Information loss under these circumstances is a normal part of BGP4 and does not indicate an error.
Aggregation ID	The router that originated this aggregator.
Aggregation AS	The AS in which the network information was aggregated. This value applies only to aggregated routes and is otherwise 0.
Originator	The originator of the route in a route reflector environment.
Cluster List	The route-reflector clusters through which this route has passed.
Learned From	The IP address of the neighbor from which the Layer 3 switch learned the route.
Admin Distance	The administrative distance of the route.
Adj_RIB_out	The number of neighbors to which the route has been or will be advertised. This is the number of times the route has been selected as the best route and placed in the Adj-RIB-Out (outbound queue) for a BGP4 neighbor.
Communities	The communities the route is in.

Displaying BGP4 route-attribute entries

The route-attribute entries table lists the sets of BGP4 attributes stored in the router memory. Each set of attributes is unique and can be associated with one or more routes. In fact, the router typically has fewer route attribute entries than routes. To display the route-attribute entries table, use one of the following methods.

To display the IP route table, enter the following command.

```
Brocade#show ip bgp attribute-entries
```

Syntax: show ip bgp attribute-entries

Here is an example of the information displayed by this command. A zero value indicates that the attribute is not set.

```
Brocade#show ip bgp attribute-entries
      Total number of BGP Attribute Entries: 7753
1      Next Hop :192.168.11.1      Metric :0      Origin:IGP
      Originator:0.0.0.0      Cluster List:None
      Aggregator:AS Number :0      Router-ID:0.0.0.0      Atomic:FALSE
      Local Pref:100      Communities:Internet
      AS Path : (65002) 65001 4355 2548 3561 5400 6669 5548
2      Next Hop :192.168.11.1      Metric :0      Origin:IGP
      Originator:0.0.0.0      Cluster List:None
      Aggregator:AS Number :0      Router-ID:0.0.0.0      Atomic:FALSE
      Local Pref:100      Communities:Internet
      AS Path : (65002) 65001 4355 2548
```

Table 249 lists the field definitions for the command output.

TABLE 249 BGP4 route-attribute entries information

Field	Description
Total number of BGP Attribute Entries	The number of routes contained in this router BGP4 route table.
Next Hop	The IP address of the next hop router for routes that have this set of attributes.
Metric	The cost of the routes that have this set of attributes.
Origin	The source of the route information. The origin can be one of the following: <ul style="list-style-type: none"> EGP – The routes with this set of attributes came to BGP through EGP. IGP – The routes with this set of attributes came to BGP through IGP. INCOMPLETE – The routes came from an origin other than one of the above. For example, they may have been redistributed from OSPF or RIP. When BGP4 compares multiple routes to a destination to select the best route, IGP is preferred over EGP and both are preferred over INCOMPLETE.
Originator	The originator of the route in a route reflector environment.
Cluster List	The route-reflector clusters through which this set of attributes has passed.
Aggregator	Aggregator information: <ul style="list-style-type: none"> AS Number shows the AS in which the network information in the attribute set was aggregated. This value applies only to aggregated routes and is otherwise 0. Router-ID shows the router that originated this aggregator.
Atomic	Whether the network information in this set of attributes has been aggregated and this aggregation has resulted in information loss: <ul style="list-style-type: none"> TRUE – Indicates information loss has occurred FALSE – Indicates no information loss has occurred NOTE: Information loss under these circumstances is a normal part of BGP4 and does not indicate an error.
Local Pref	The degree of preference for routes that use this set of attributes relative to other routes in the local AS.
Communities	The communities that routes with this set of attributes are in.
AS Path	The autonomous systems through which routes with this set of attributes have passed. The local AS is shown in parentheses.

Displaying the routes BGP4 has placed in the IP route table

The IP route table indicates the routes it has received from BGP4 by listing “BGP” as the route type.

To display the IP route table, enter the following command.

```
Brocade#show ip route
```

Syntax: `show ip route [<ip-addr> | <num> | bgp | ospf | rip]`

Here is an example of the information displayed by this command. Notice that most of the routes in this example have type “B”, indicating that their source is BGP4.

```

Brocade#show ip route
Total number of IP routes: 50834
B:BGP D:Directly-Connected O:OSPF R:RIP S:Static
  Network Address  NetMask          Gateway          Port      Cost    Type
  3.0.0.0          255.0.0.0        192.168.13.2    1/1       0       B
  4.0.0.0          255.0.0.0        192.168.13.2    1/1       0       B
  9.20.0.0         255.255.128.0    192.168.13.2    1/1       0       B
  10.1.0.0         255.255.0.0      0.0.0.0         1/1       1       D
  10.10.11.0       255.255.255.0    0.0.0.0         2/24      1       D
  12.2.97.0        255.255.255.0    192.168.13.2    1/1       0       B
  12.3.63.0        255.255.255.0    192.168.13.2    1/1       0       B
  12.3.123.0       255.255.255.0    192.168.13.2    1/1       0       B
  12.5.252.0       255.255.254.0    192.168.13.2    1/1       0       B
  12.6.42.0        255.255.254.0    192.168.13.2    1/1       0       B
remaining 50824 entries not shown...

```

Displaying route flap dampening statistics

To display route dampening statistics or all the dampened routes, enter the following command at any level of the CLI.

```

Brocade#show ip bgp flap-statistics
Total number of flapping routes: 414
  Status Code  >:best d:damped h:history *:valid
  Network      From          Flaps Since      Reuse      Path
h> 192.50.206.0/23 166.90.213.77 1 0 :0 :13 0 :0 :0 65001 4355 1 701
h> 203.255.192.0/20 166.90.213.77 1 0 :0 :13 0 :0 :0 65001 4355 1 7018
h> 203.252.165.0/24 166.90.213.77 1 0 :0 :13 0 :0 :0 65001 4355 1 7018
h> 192.50.208.0/23 166.90.213.77 1 0 :0 :13 0 :0 :0 65001 4355 1 701
h> 133.33.0.0/16 166.90.213.77 1 0 :0 :13 0 :0 :0 65001 4355 1 701
*> 204.17.220.0/24 166.90.213.77 1 0 :1 :4 0 :0 :0 65001 4355 701 62

```

Syntax: `show ip bgp flap-statistics [regular-expression <regular-expression> | <address> <mask> [longer-prefixes] | neighbor <ip-addr> | filter-list <num>...]`

The **regular-expression** <regular-expression> parameter is a regular expression. The regular expressions are the same ones supported for BGP4 AS-path filters. Refer to [“Using regular expressions to filter”](#) on page 1397.

The <address> <mask> parameter specifies a particular route. If you also use the optional **longer-prefixes** parameter, then all statistics for routes that match the specified route or have a longer prefix than the specified route are displayed. For example, if you specify **209.157.0.0 longer**, then all routes with the prefix 209.157 or that have a longer prefix (such as 209.157.22) are displayed.

The **neighbor** <ip-addr> parameter displays route flap dampening statistics only for routes learned from the specified neighbor. You also can display route flap statistics for routes learned from a neighbor by entering the following command: **show ip bgp neighbors <ip-addr> flap-statistics**.

The **filter-list** <num> parameter specifies one or more filters. Only the routes that have been dampened and that match the specified filters are displayed.

[Table 250](#) lists the field definitions for the command output.

TABLE 250 Route flap dampening statistics

Field	Description
Total number of flapping routes	The total number of routes in the Layer 3 switch BGP4 route table that have changed state and thus have been marked as flapping routes.
Status code	Indicates the dampening status of the route, which can be one of the following: <ul style="list-style-type: none"> • > – This is the best route among those in the BGP4 route table to the route destination. • d – This route is currently dampened, and thus unusable. • h – The route has a history of flapping and is unreachable now. • * – The route has a history of flapping but is currently usable.
Network	The destination network of the route.
From	The neighbor that sent the route to the Layer 3 switch.
Flaps	The number of flaps (state changes) the route has experienced.
Since	The amount of time since the first flap of this route.
Reuse	The amount of time remaining until this route will be un-suppressed and thus be usable again.
Path	Shows the AS-path information for the route.

You also can display all the dampened routes by entering the following command.

show ip bgp dampened-paths.

Displaying the active route map configuration

To view the device active route map configuration (contained in the running-config) without displaying the entire running-config, enter the following command at any level of the CLI.

```
Brocade#show route-map
route-map permitnet4 permit 10
  match ip address prefix-list plist1
route-map permitnet1 permit 1
  match ip address prefix-list plist2
route-map setcomm permit 1
  set community 1234:2345 no-export
route-map test111 permit 111
  match address-filters 11
  set community 11:12 no-export
route-map permit1122 permit 12
  match ip address 11
route-map permit1122 permit 13
  match ip address std_22
```

This example shows that the running-config contains six route maps. Notice that the match and set statements within each route map are listed beneath the command for the route map itself. In this simplified example, each route map contains only one match or set statement.

To display the active configuration for a specific route map, enter a command such as the following, which specifies a route map name.

```
Brocade#show route-map setcomm
route-map setcomm permit 1
set community 1234:2345 no-export
```

This example shows the active configuration for a route map called “setcomm”.

Syntax: `show route-map [<map-name>]`

Displaying BGP4 graceful restart neighbor information

Use the **show ip bgp neighbors** command to display BGP4 restart information for BGP4 neighbors.

```
Brocade# show ip bgp neighbors
Total number of BGP Neighbors: 6
1  IP Address: 50.50.50.10, AS: 20 (EBGP), RouterID: 10.10.10.20
State: ESTABLISHED, Time: 0h0m18s, KeepAliveTime: 60, HoldTime: 180
KeepAliveTimer Expire in 34 seconds, HoldTimer Expire in 163 seconds
Minimum Route Advertisement Interval: 0 seconds
RefreshCapability: Received
GracefulRestartCapability: Received
  Restart Time 120 sec, Restart bit 0
  afi/safi 1/1, Forwarding bit 0
GracefulRestartCapability: Sent
  Restart Time 120 sec, Restart bit 0
  afi/safi 1/1, Forwarding bit 1
Messages:      Open      Update  KeepAlive Notification Refresh-Req
```

The text in bold is the BGP4 restart information for the specified neighbor.

Syntax: `show ip bgp neighbors`

Updating route information and resetting a neighbor session

The following sections describe ways to update route information with a neighbor, reset the session with a neighbor, and close a session with a neighbor.

Whenever you change a policy (ACL, route map, and so on) that affects the routes that the Layer 3 switch learns from a BGP4 neighbor or peer group of neighbors, you must enter a command to place the changes into effect. The changes take place automatically, but only affect new route updates. To make changes retroactive for routes received or sent before the changes were made, you need to enter a clear command.

You can update the learned routes using either of the following methods:

- Request the complete BGP4 route table from the neighbor or peer group. You can use this method if the neighbor supports the refresh capability (RFCs 2842 and 2858).
- Clear (reset) the session with the neighbor or peer group. This is the only method you can use if the neighbor does not support the refresh capability.

Each of these methods is effective, but can be disruptive to the network. The first method adds overhead while the Layer 3 switch learns and filters the neighbor or group entire route table, while the second method adds more overhead while the devices re-establish their BGP4 sessions.

You also can clear and reset the BGP4 routes that have been installed in the IP route table. Refer to [“Clearing and resetting BGP4 routes in the IP route table”](#) on page 1458.

Using soft reconfiguration

The *soft reconfiguration* feature places policy changes into effect without resetting the BGP4 session. Soft reconfiguration does not request the neighbor or group to send its entire BGP4 table, nor does the feature reset the session with the neighbor or group. Instead, the soft reconfiguration feature stores all the route updates received from the neighbor or group. When you request a soft reset of inbound routes, the software performs route selection by comparing the policies against the stored route updates, instead of requesting the neighbor BGP4 route table or resetting the session with the neighbor.

When you enable the soft reconfiguration feature, it sends a refresh message to the neighbor or group if the neighbor or group supports dynamic refresh. Otherwise, the feature resets the neighbor session. This step is required to ensure that the soft reconfiguration feature has a complete set of updates to use, and occurs only once, when you enable the feature. The feature accumulates all the route updates from the neighbor, eliminating the need for additional refreshes or resets when you change policies in the future.

To use soft reconfiguration:

- Enable the feature.
- Make the policy changes.
- Apply the changes by requesting a soft reset of the inbound updates from the neighbor or group.

Use the following CLI methods to configure soft configuration, apply policy changes, and display information for the updates that are filtered out by the policies.

Enabling soft reconfiguration

To configure a neighbor for soft reconfiguration, enter a command such as the following.

```
Brocade(config-bgp-router)#neighbor 10.10.200.102 soft-reconfiguration inbound
```

This command enables soft reconfiguration for updates received from 10.10.200.102. The software dynamically refreshes or resets the session with the neighbor, then retains all route updates from the neighbor following the reset.

Syntax: [no] neighbor <ip-addr> | <peer-group-name> soft-reconfiguration inbound

NOTE

The syntax related to soft reconfiguration is shown. For complete command syntax, refer to [“Adding BGP4 neighbors”](#) on page 1354.

Placing a policy change into effect

To place policy changes into effect, enter a command such as the following.

```
Brocade(config-bgp-router)#clear ip bgp neighbor 10.10.200.102 soft in
```

This command updates the routes by comparing the route policies against the route updates that the Layer 3 switch has stored. The command does not request additional updates from the neighbor or otherwise affect the session with the neighbor.

Syntax: clear ip bgp neighbor <ip-addr> | <peer-group-name> soft in

NOTE

If you do not specify “in”, the command applies to both inbound and outbound updates.

NOTE

The syntax related to soft reconfiguration is shown. For complete command syntax, refer to [“Dynamically refreshing routes”](#) on page 1455.

Displaying the filtered routes received from the neighbor or peer group

When you enable soft reconfiguration, the Layer 3 switch saves all updates received from the specified neighbor or peer group. This includes updates that contain routes that are filtered out by the BGP4 route policies in effect on the Layer 3 switch. To display the routes that have been filtered out, enter the following command at any level of the CLI.

```
Brocade#show ip bgp filtered-routes
Searching for matching routes, use ^C to quit...
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
      E:EBGP H:HISTORY I:IBGP L:LOCAL M:MULTIPATH S:SUPPRESSED F:FILTERED
      Prefix          Next Hop      Metric      LocPrf      Weight Status
1      3.0.0.0/8       192.168.4.106
      AS_PATH: 65001 4355 701 80
2      4.0.0.0/8       192.168.4.106
      AS_PATH: 65001 4355 1
3      4.60.212.0/22   192.168.4.106
      AS_PATH: 65001 4355 701 1 189
```

The routes displayed by the command are the routes that the Layer 3 switch BGP4 policies filtered out. The Layer 3 switch did not place the routes in the BGP4 route table, but did keep the updates. If a policy change causes these routes to be permitted, the Layer 3 switch does not need to request the route information from the neighbor, but instead uses the information in the updates.

Syntax: `show ip bgp filtered-routes [<ip-addr>] | [as-path-access-list <num>] | [detail] | [prefix-list <string>]`

The *<ip-addr>* parameter specifies the IP address of the destination network.

The **as-path-access-list** *<num>* parameter specifies an AS-path ACL. Only the routes permitted by the AS-path ACL are displayed.

The **detail** parameter displays detailed information for the routes. (The example above shows summary information.) You can specify any of the other options after **detail** to further refine the display request.

The **prefix-list** *<string>* parameter specifies an IP prefix list. Only the routes permitted by the prefix list are displayed.

NOTE

The syntax for displaying filtered routes is shown. For complete command syntax, refer to [“Displaying the BGP4 route table”](#) on page 1441.

Displaying all the routes received from the neighbor

To display all the route information received in route updates from a neighbor since you enabled soft reconfiguration, enter a command such as the following at any level of the CLI.

```
Brocade#show ip bgp neighbors 192.168.4.106 received-routes

```

Syntax: `show ip bgp neighbors <ip-addr> received-routes [detail]`

The **detail** parameter displays detailed information for the routes. The example above shows summary information.

NOTE

The syntax for displaying received routes is shown. For complete command syntax, refer to [“Displaying BGP4 neighbor information”](#) on page 1428.

NOTE

The `show ip bgp neighbors <ip-addr> received-routes` syntax supported in previous software releases is changed to the following syntax: `show ip bgp neighbors <ip-addr> routes`.

Dynamically requesting a route refresh from a BGP4 neighbor

You can easily apply changes to filters that control BGP4 routes received from or advertised to a neighbor, without resetting the BGP4 session between the Layer 3 switch and the neighbor. For example, if you add, change, or remove a BGP4 address filter that denies specific routes received from a neighbor, you can apply the filter change by requesting a route refresh from the neighbor. If the neighbor also supports dynamic route refreshes, the neighbor resends its Adj-RIB-Out, its table of BGP4 routes. Using the route refresh feature, you do not need to reset the session with the neighbor.

The route refresh feature is based on the following specifications:

- RFC 2842. This RFC specifies the Capability Advertisement, which a BGP4 router uses to dynamically negotiate a capability with a neighbor.
- RFC 2858 for Multi-protocol Extension.

NOTE

The Brocade implementation of dynamic route refresh supports negotiation of IP version 4 unicasts only.

- RFC 2918, which describes the dynamic route refresh capability

The dynamic route refresh capability is enabled by default and cannot be disabled. When the Layer 3 switch sends a BGP4 OPEN message to a neighbor, the Layer 3 switch includes a Capability Advertisement to inform the neighbor that the Layer 3 switch supports dynamic route refresh.

NOTE

The option for dynamically refreshing routes received from a neighbor requires the neighbor to support dynamic route refresh. If the neighbor does not support this feature, the option does not take effect and the software displays an error message. The option for dynamically re-advertising routes to a neighbor does not require the neighbor to support dynamic route refresh.

To use the dynamic refresh feature, use either of the following methods.

Dynamically refreshing routes

The following sections describe how to dynamically refresh BGP4 routes to place new or changed filters into effect.

To request a dynamic refresh of all routes from a neighbor, enter a command such as the following.

```
Brocade(config-bgp-router)#clear ip bgp neighbor 192.168.1.170 soft in
```

This command asks the neighbor to send its BGP4 table (Adj-RIB-Out) again. The Layer 3 switch applies its filters to the incoming routes and adds, modifies, or removes BGP4 routes as necessary.

Syntax: `clear ip bgp neighbor all | <ip-addr> | <peer-group-name> | <as-num> [soft-outbound | soft [in | out]]`

The **all** | *<ip-addr>* | *<peer-group-name>* | *<as-num>* option specifies the neighbor. The *<ip-addr>* parameter specifies a neighbor by its IP interface with the Layer 3 switch. The *<peer-group-name>* specifies all neighbors in a specific peer group. The *<as-num>* parameter specifies all neighbors within the specified AS. The **all** parameter specifies all neighbors.

The **soft-outbound** parameter updates all outbound routes by applying the new or changed filters, but sends only the existing routes affected by the new or changed filters to the neighbor.

The **soft [in | out]** parameter specifies whether you want to refresh the routes received from the neighbor or sent to the neighbor:

- **soft in** does one of the following:
 - If you enabled soft reconfiguration for the neighbor or peer group, **soft in** updates the routes by comparing the route policies against the route updates that the Layer 3 switch has stored. Soft reconfiguration does not request additional updates from the neighbor or otherwise affect the session with the neighbor. Refer to [“Using soft reconfiguration”](#) on page 1452.
 - If you did not enable soft reconfiguration, **soft in** requests the neighbor entire BGP4 route table (Adj-RIB-Out), then applies the filters to add, change, or exclude routes.
 - If a neighbor does not support dynamic refresh, **soft in** resets the neighbor session.
- **soft out** updates all outbound routes, then sends the Layer 3 switch entire BGP4 route table (Adj-RIB-Out) to the neighbor, after changing or excluding the routes affected by the filters.

If you do not specify **in** or **out**, the Layer 3 switch performs both options.

NOTE

The **soft-outbound** parameter updates all outbound routes by applying the new or changed filters, but sends only the existing routes affected by the new or changed filters to the neighbor. The **soft out** parameter updates all outbound routes, then sends the Layer 3 switch entire BGP4 route table (Adj-RIB-Out) to the neighbor, after changing or excluding the routes affected by the filters. Use **soft-outbound** if only the outbound policy is changed.

To dynamically resend all the Layer 3 switch BGP4 routes to a neighbor, enter a command such as the following.

```
Brocade(config-bgp-router)#clear ip bgp neighbor 192.168.1.170 soft out
```

This command applies its filters for outgoing routes to the Layer 3 switch BGP4 route table (Adj-RIB-Out), changes or excludes routes accordingly, then sends the resulting Adj-RIB-Out to the neighbor.

NOTE

The Brocade Layer 3 switch does not automatically update outbound routes using a new or changed outbound policy or filter when a session with the neighbor goes up or down. Instead, the Layer 3 switch applies a new or changed policy or filter when a route is placed in the outbound queue (Adj-RIB-Out).

To place a new or changed outbound policy or filter into effect, you must enter a **clear ip bgp neighbor** command regardless of whether the neighbor session is up or down. You can enter the command without optional parameters or with the **soft out** or **soft-outbound** option. Either way, you must specify a parameter for the neighbor (<ip-addr>, <as-num>, <peer-group-name>, or **all**).

Displaying dynamic refresh information

You can use the **show ip bgp neighbors** command to display information for dynamic refresh requests. For each neighbor, the display lists the number of dynamic refresh requests the Layer 3 switch has sent to or received from the neighbor and indicates whether the Layer 3 switch received confirmation from the neighbor that the neighbor supports dynamic route refresh.

The RefreshCapability field indicates whether this Layer 3 switch has received confirmation from the neighbor that the neighbor supports the dynamic refresh capability. The statistics in the Message Sent and Message Received rows under Refresh-Req indicate how many dynamic refreshes have been sent to and received from the neighbor. The statistic is cumulative across sessions.

```

Brocade#show ip bgp neighbors 10.4.0.2
1  IP Address: 10.4.0.2, AS: 5 (EBGP), RouterID: 100.0.0.1

```

Closing or resetting a neighbor session

You can close a neighbor session or resend route updates to a neighbor.

If you make changes to filters or route maps and the neighbor does not support dynamic route refresh, use the following methods to ensure that neighbors contain only the routes you want them to contain:

- If you close a neighbor session, the Layer 3 switch and the neighbor clear all the routes they learned from each other. When the Layer 3 switch and neighbor establish a new BGP4 session, they exchange route tables again. Use this method if you want the Layer 3 switch to relearn routes from the neighbor and resend its own route table to the neighbor.
- If you use the soft-outbound option, the Layer 3 switch compiles a list of all the routes it would normally send to the neighbor at the beginning of a session. However, before sending the updates, the Brocade Layer 3 switch also applies the filters and route maps you have configured to the list of routes. If the filters or route maps result in changes to the list of routes, the Layer 3 switch sends updates to advertise, change, or even withdraw routes on the

neighbor as needed. This ensures that the neighbor receives only the routes you want it to contain. Even if the neighbor already contains a route learned from the Layer 3 switch that you later decided to filter out, using the soft-outbound option removes that route from the neighbor.

You can specify a single neighbor or a peer group.

To close a neighbor session and thus flush all the routes exchanged by the Layer 3 switch and the neighbor, enter the following command.

```
Brocade#clear ip bgp neighbor all
```

Syntax: `clear ip bgp neighbor all | <ip-addr> | <peer-group-name> | <as-num> [soft-outbound | soft [in | out]]`

The `all` | `<ip-addr>` | `<peer-group-name>` | `<as-num>` option specifies the neighbor. The `<ip-addr>` parameter specifies a neighbor by its IP interface with the Layer 3 switch. The `<peer-group-name>` specifies all neighbors in a specific peer group. The `<as-num>` parameter specifies all neighbors within the specified AS. The `all` parameter specifies all neighbors.

To resend routes to a neighbor without closing the neighbor session, enter a command such as the following.

```
Brocade#clear ip bgp neighbor 10.0.0.1 soft out
```

Clearing and resetting BGP4 routes in the IP route table

To clear BGP4 routes from the IP route table and reset the routes, enter a command such as the following.

```
Brocade#clear ip bgp routes
```

Syntax: `clear ip bgp routes [<ip-addr>/<prefix-length>]`

NOTE

The `clear ip bgp routes` command has the same effect as the `clear ip route` command, but applies only to routes that come from BGP4.

Clearing traffic counters

You can clear the counters (reset them to 0) for BGP4 messages. To do so, use one of the following methods.

To clear the BGP4 message counter for all neighbors, enter the following command.

```
Brocade#clear ip bgp traffic
```

Syntax: `clear ip bgp traffic`

To clear the BGP4 message counter for a specific neighbor, enter a command such as the following.

```
Brocade#clear ip bgp neighbor 10.0.0.1 traffic
```

To clear the BGP4 message counter for all neighbors within a peer group, enter a command such as the following.

```
Brocade#clear ip bgp neighbor PeerGroup1 traffic
```

Syntax: `clear ip bgp neighbor all | <ip-addr> | <peer-group-name> | <as-num> traffic`

The **all** | *<ip-addr>* | *<peer-group-name>* | *<as-num>* option specifies the neighbor. The *<ip-addr>* parameter specifies a neighbor by its IP interface with the Layer 3 switch. The *<peer-group-name>* specifies all neighbors in a specific peer group. The *<as-num>* parameter specifies all neighbors within the specified AS. The **all** parameter specifies all neighbors.

Clearing route flap dampening statistics

To clear route flap dampening statistics, use the following CLI method.

NOTE

Clearing the dampening statistics for a route does not change the dampening status of the route.

To clear all the route dampening statistics, enter the following command at any level of the CLI.

```
Brocade#clear ip bgp flap-statistics
```

Syntax: `clear ip bgp flap-statistics [regular-expression <regular-expression> | <address> <mask> | neighbor <ip-addr>]`

The parameters are the same as those for the **show ip bgp flap-statistics** command (except the **longer-prefixes** option is not supported). Refer to “[Displaying route flap dampening statistics](#)” on page 1419.

NOTE

The **clear ip bgp damping** command not only clears statistics but also un-suppresses the routes. Refer to “[Displaying route flap dampening statistics](#)” on page 1419.

Removing route flap dampening

You can un-suppress routes by removing route flap dampening from the routes. The Layer 3 switch allows you to un-suppress all routes at once or un-suppress individual routes.

To un-suppress all the suppressed routes, enter the following command at the Privileged EXEC level of the CLI.

```
Brocade#clear ip bgp damping
```

Syntax: `clear ip bgp damping [<ip-addr> <ip-mask>]`

The *<ip-addr>* parameter specifies a particular network.

The *<ip-mask>* parameter specifies the network mask.

To un-suppress a specific route, enter a command such as the following.

```
Brocade#clear ip bgp damping 209.157.22.0 255.255.255.0
```

This command un-suppresses only the routes for network 209.157.22.0/24.

Clearing diagnostic buffers

The Layer 3 switch stores the following BGP4 diagnostic information in buffers:

- The first 400 bytes of the last packet that contained an error
- The last NOTIFICATION message either sent or received by the Layer 3 switch

To display these buffers, use options with the **show ip bgp neighbors** command. Refer to [“Displaying BGP4 neighbor information”](#) on page 1428.

This information can be useful if you are working with Brocade Technical Support to resolve a problem. The buffers do not identify the system time when the data was written to the buffer. If you want to ensure that diagnostic data in a buffer is recent, you can clear the buffers. You can clear the buffers for a specific neighbor or for all neighbors.

If you clear the buffer containing the first 400 bytes of the last packet that contained errors, all the bytes are changed to zeros. The Last Connection Reset Reason field of the BGP neighbor table also is cleared.

If you clear the buffer containing the last NOTIFICATION message sent or received, the buffer contains no data.

You can clear the buffers for all neighbors, for an individual neighbor, or for all the neighbors within a specific peer group.

To clear these buffers for neighbor 10.0.0.1, enter the following commands.

```
Brocade#clear ip bgp neighbor 10.0.0.1 last-packet-with-error
Brocade#clear ip bgp neighbor 10.0.0.1 notification-errors
```

Syntax: **clear ip bgp neighbor** **all** | *<ip-addr>* | *<peer-group-name>* | *<as-num>*
last-packet-with-error | **notification-errors**

The **all** | *<ip-addr>* | *<peer-group-name>* | *<as-num>* option specifies the neighbor. The *<ip-addr>* parameter specifies a neighbor by its IP interface with the Layer 3 switch. The *<peer-group-name>* specifies all neighbors in a specific peer group. The *<as-num>* parameter specifies all neighbors within the specified AS. The **all** parameter specifies all neighbors.

IP Multicast Traffic Reduction on Brocade FastIron X Series switches

Table 251 lists the individual Brocade FastIron X Series switches and the IP multicast traffic reduction features they support. These features are supported in the Layer 2, base Layer 3, and full Layer 3 software images, except where explicitly noted.

TABLE 251 Supported IP multicast reduction features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
IGMP v1/v2 Snooping Global	Yes	For details about IP multicast traffic reduction on FastIron WS and Brocade FCX Series and Brocade ICX 6610 Series switches, refer to "IGMP snooping configuration" on page 1497.			Yes
IGMP v3 Snooping Global	Yes (*,G)				Yes
IGMP v1/v2/v3 Snooping per VLAN	Yes				Yes
IGMP v2/v3 Fast Leave (membership tracking)	Yes				Yes
PIM-SM V2 Snooping	Yes				Yes

IGMP snooping overview

When a device processes a multicast packet, by default, it broadcasts the packets to all ports except the incoming port of a VLAN. Packets are flooded by hardware without going to the CPU. This behavior causes some clients to receive unwanted traffic.

IGMP snooping provides multicast containment by forwarding traffic to only the ports that have IGMP receivers for a specific multicast group (destination address). A device maintains the IGMP group membership information by processing the IGMP reports and leave messages, so traffic can be forwarded to ports receiving IGMP reports.

An IPv4 multicast address is a destination address in the range of 224.0.0.0 to 239.255.255.255. Addresses of 224.0.0.X are reserved. Because packets destined for these addresses may require VLAN flooding, devices do not snoop in the reserved range. Data packets destined to addresses in the reserved range are flooded to the entire VLAN by hardware, and mirrored to the CPU. Multicast data packets destined for the non-reserved range of addresses are snooped. A client must send IGMP reports in order to receive traffic. If an application outside the reserved range requires VLAN flooding, the user must configure a static group that applies to the entire VLAN.

An IGMP device's responsibility is to broadcast general queries periodically, and to send group queries when receiving a leave message, to confirm that none of the clients on the port still want specific traffic before removing the traffic from the port. IGMP V2 lets clients specify what group (destination address) will receive the traffic but not to specify the source of the traffic. IGMP V3 is for source-specific multicast traffic, adding the capability for clients to INCLUDE or EXCLUDE specific traffic sources. An IGMP V3 device port state could be INCLUDE or EXCLUDE, and there are different types of group records for client reports.

The interfaces respond to general or group queries by sending a membership report that contains one or more of the following records associated with a specific group:

- Current-state record that indicates from which sources the interface wants to receive and not receive traffic. This record contains the source address of interfaces and whether or not traffic will be included (IS_IN) or not excluded (IS_EX) from this source.
- Filter-mode-change record. If the interface state changes from IS_IN to IS_EX, a TO_EX record is included in the membership report. Likewise, if the interface state changes from IS_EX to IS_IN, a TO_IN record appears in the membership report.
- An IGMP V2 leave report is equivalent to a TO_IN (empty) record in IGMP V3. This record means that no traffic from this group will be received regardless of the source.
- An IGMP V2 group report is equivalent to an IS_EX (empty) record in IGMP V3. This record means that all traffic from this group will be received regardless of source.
- Source-list-change record. If the interface wants to add or remove traffic sources from its membership report, the report can contain an ALLOW record, which includes a list of new sources from which the interface wishes to receive traffic. It can also contain a BLOCK record, which lists the current traffic sources from which the interface wants to stop receiving traffic.

IGMP protocols provide a method for clients and a device to exchange messages, and let the device build a database indicating which port wants what traffic. The protocols do not specify forwarding methods. They require IGMP snooping or multicast protocols such as PIM or DVMRP to handle packet forwarding. PIM or DVMRP can route multicast packets within and outside a VLAN, while IGMP snooping can switch packets only within a VLAN.

If a VLAN is not IGMP snooping-enabled, it floods multicast data and control packets to the entire VLAN in hardware. When snooping is enabled, IGMP packets are trapped to the CPU. Data packets are mirrored to the CPU in addition to being VLAN flooded. The CPU then installs hardware resources, so that subsequent data packets can be switched to desired ports in hardware without going to the CPU. If there is no client report or port to queriers for a data stream, the hardware resource drops it.

MAC-based implementation on FastIron X Series devices

On both switch and router software images, IGMP snooping is MAC-based. This differs from IGMP snooping on the BigIron router images, which match on both IP source and group (S,G) entries programmed in the Layer 4 CAM. In contrast, the FastIron X Series images match on Layer 2 destination MAC address entries (*,G).

When Layer 2 CAM is used, traffic is switched solely based on the destination MAC address. Consequently, traffic of the same group coming to the same port, regardless of its source, is switched in the same way. In addition, the lowest 23 bits of the group address are mapped to a MAC address. In this way, multiple groups (for example, 224.1.1.1 and 225.1.1.1) have the same

MAC address. Groups having the same MAC address are switched to the same destination ports, which are the superset of individual group output ports. Thus, the use of Layer 2 CAM might cause unwanted packets to be sent to some ports. However, the switch generally needs far less Layer 2 CAM than it does Layer 4 CAM, which is required for each stream with a different source and group.

Queriers and non-queriers

An IGMP snooping-enabled Brocade device can be configured as a querier (active) or non-querier (passive). An IGMP querier sends queries; a non-querier listens for IGMP queries and forwards them to the entire VLAN. VLANs can be independently configured to be queriers or non-queriers. If a VLAN has a connection to a PIM- or DVMRP-enabled port on another router, the VLAN must be configured as a non-querier. When multiple IGMP snooping devices are connected together, and there is no connection to a PIM- or DVMRP-enabled port, one of the devices must be configured as a querier. If multiple devices are configured as queriers, after these devices exchange queries, then all except the winner stop sending queries. The device with the lowest address becomes the querier. Although the system will work when multiple devices are configured as queriers, Brocade recommends that only one device (preferably the one with the traffic source) is configured as a querier.

The non-queriers always forward multicast data traffic and IGMP messages to router ports which receive IGMP queries or PIM or DVMRP hellos. Brocade recommends that you configure the device with the data traffic source (server) as a querier. If a server is attached to a non-querier, the non-querier always forwards traffic to the querier regardless of whether there are any clients on the querier.

NOTE

In a topology of one or more connecting devices, at least one device must be running PIM or DVMRP configured as active. Otherwise, none of the devices can send out queries, and traffic cannot be forwarded to clients.

VLAN-specific configuration

IGMP snooping can be enabled on some VLANs or on all VLANs. Each VLAN can be independently configured to be a querier or non-querier and can be configured for IGMP V2 or IGMP V3. In general, the **ip multicast** commands apply globally to all VLANs except those configured with VLAN-specific multicast commands. The VLAN-specific multicast commands supersede the global **ip multicast** commands.

IGMP snooping can be configured for IGMP V2 or IGMP V3 on individual ports of a VLAN. An interface or router sends the queries and reports that include its IGMP version specified on it. The version configuration only applies to sending queries. The snooping device recognizes and processes IGMP V2 and IGMP V3 packets regardless of the version configuration.

To avoid version deadlock, an interface retains its version configuration even when it receives a report with a lower version.

Tracking and fast leave

Brocade devices support fast leave for IGMP V2, and tracking and fast leave for IGMP V3. Fast leave stops the traffic immediately when the port receives a leave message. Tracking traces all IGMP V3 clients. Refer to [“Enabling IGMP V3 membership tracking and fast leave for the VLAN”](#) on page 1474 and [“Enabling fast leave for IGMP V2”](#) on page 1475.

Support for IGMP snooping and Layer 3 multicast routing together on the same device

The Brocade device supports global Layer 2 IP multicast traffic reduction (IGMP snooping) and Layer 3 multicast routing (DVMRP or PIM-Sparse or PIM-Dense) together on the same device in the full Layer 3 software image, as long as the Layer 2 feature configuration is at the VLAN level.

Refer to [“IP multicast protocols and IGMP snooping on the same device”](#) on page 1606.

Configuration notes and feature limitations for IGMP snooping and Layer 3 multicast routing

The following details apply to FastIron X Series devices:

- Layer 2 IGMP snooping is automatically enabled with Layer 3 multicast routing. If Layer 3 multicast routing is enabled on your system, do not attempt to enable Layer 2 IGMP snooping.
- The default IGMP version is V2.
- A user can configure the maximum numbers of group address entries.
- An IGMP device can be configured to rate-limit the forwarding IGMP V2 membership reports to queriers.
- The device supports static groups. The device acts as a proxy to send IGMP reports for the static groups when receiving queries.
- A user can configure static router ports to force all multicast traffic to these specific ports.
- If a VLAN has a connection to a PIM- or DVMRP-enabled port on another router, the VLAN must be configured as a non-querier (passive). When multiple snooping devices connect together and there is no connection to PIM or DVMRP ports, one device must be configured as a querier (active). If multiple devices are configured as active (queriers), only one will keep sending queries after exchanging queries.
- The querier must configure an IP address to send out queries.
- IGMP snooping requires hardware resource. Hardware resource is installed only when there is data traffic. If resource is inadequate, the data stream without a resource is mirrored to the CPU in addition to being VLAN flooded, which can cause high CPU usage. Brocade recommends that you avoid global enabling of snooping unless necessary.
- IGMP snooping requires clients to send membership reports in order to receive data traffic. If a client application does not send reports, you must configure static groups on the snooping VLAN to force traffic to client ports. Note that servers (traffic sources) are not required to send IGMP memberships.
- FastIron X Series devices support VSRP together with IGMP snooping on the same interface.
- When VSRP or VSRP-aware is configured on a VLAN, the VLAN will support IGMP snooping version 2 only. IGMP version 3 will not be supported on the VLAN.
- High CPU utilization occurs when IGMP Snooping and PIM or DVMRP routing are enabled simultaneously on FastIron X Series devices. With IGMP snooping and PIM or DVMRP Routing enabled simultaneously on a given system, IP Multicast data packets received in the snooping VLAN(s) are forwarded to client ports via the hardware; however, copies of these packets will also be received and dropped by the CPU.

PIM SM traffic snooping overview

When multiple PIM sparse routers connect through a snooping-enabled device, the Brocade device always forwards multicast traffic to these routers. For example, PIM sparse routers R1, R2, and R3 connect through a device. Assume R2 needs traffic, and R1 sends it to the device, which forwards it to both R2 and R3, even though R3 does not need it. A PIM SM snooping-enabled device listens to join and prune messages exchanged by PIM sparse routers, and stops traffic to the router that sends prune messages. This allows the device to forward the data stream to R2 only.

PIM SM traffic snooping requires IGMP snooping to be enabled on the device. IGMP snooping configures the device to listen for IGMP messages. PIM SM traffic snooping provides a finer level of multicast traffic control by configuring the device to listen specifically for PIM SM join and prune messages sent from one PIM SM router to another through the device.

Application examples of PIM SM traffic snooping

[Figure 170](#) shows an example application of the PIM SM traffic snooping feature. In this example, a device is connected through an IP router to a PIM SM group source that is sending traffic for two PIM SM groups. The device also is connected to a receiver for each of the groups.

When PIM SM traffic snooping is enabled, the device starts listening for PIM SM join and prune messages and IGMP group membership reports. Until the device receives a PIM SM join message or an IGMP group membership report, the device forwards IP multicast traffic out all ports. Once the device receives a join message or group membership report for a group, the device forwards subsequent traffic for that group only on the ports from which the join messages or IGMP reports were received.

In this example, the router connected to the receiver for group 239.255.162.1 sends a join message toward the group source. Because PIM SM traffic snooping is enabled on the device, the device examines the join message to learn the group ID, then makes a forwarding entry for the group ID and the port connected to the receiver router. The next time the device receives traffic for 239.255.162.1 from the group source, the device forwards the traffic only on port 5/1, because that is the only port connected to a receiver for the group.

Notice that the receiver for group 239.255.162.69 is directly connected to the device. As a result, the device does not see a join message on behalf of the client. However, because IGMP snooping also is enabled, the device uses the IGMP group membership report from the client to select the port for forwarding traffic to group 239.255.162.69 receivers.

The IGMP snooping feature and the PIM SM traffic snooping feature together build a list of groups and forwarding ports for the VLAN. The list includes PIM SM groups learned through join messages as well as MAC addresses learned through IGMP group membership reports. In this case, even though the device never sees a join message for the receiver for group 239.255.162.69, the device nonetheless learns about the receiver and forwards group traffic to the receiver.

The device stops forwarding IP multicast traffic on a port for a group if the port receives a prune message for the group.

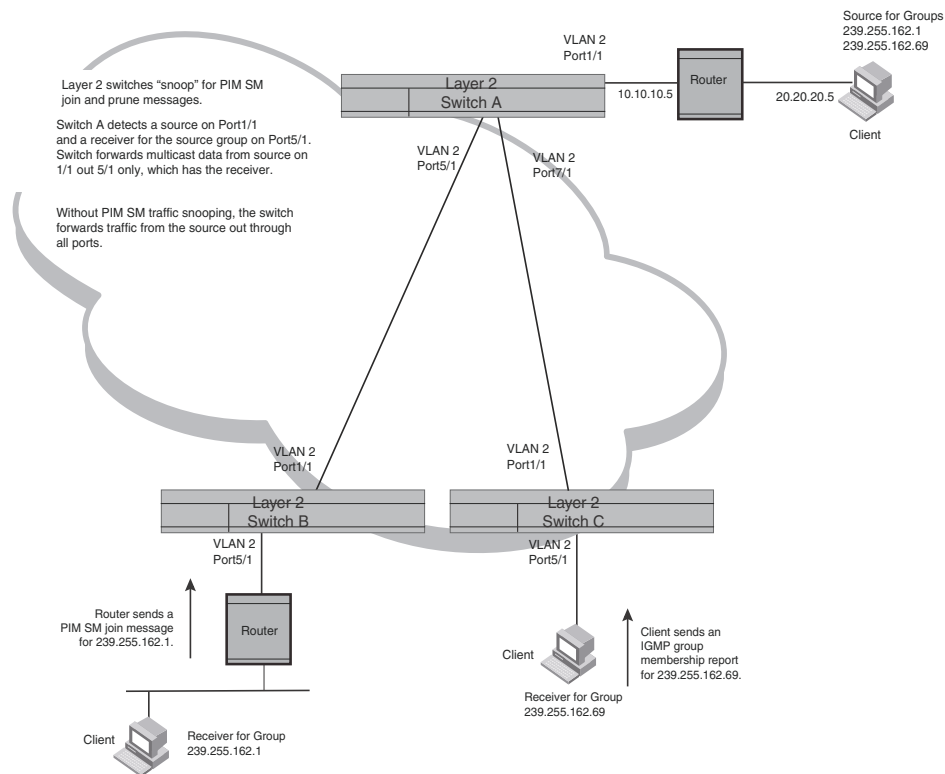

Notice that the ports connected to the source and the receivers are all in the same port-based VLAN on the device. This is required for the PIM SM snooping feature. The devices on the edge of the Global Ethernet cloud are configured for IGMP snooping and PIM SM traffic snooping. Although this application uses multiple devices, the feature has the same requirements and works the same way as it does on a single device.

The following figure shows another example application for PIM SM traffic snooping. This example shows devices on the edge of a Global Ethernet cloud (a Layer 2 Packet over SONET cloud). Assume that each device is attached to numerous other devices such as other Layer 2 Switches and Layer 3 Switches (routers).

NOTE

This example assumes that the devices are actually Brocade devices running Layer 2 Switch software.

FIGURE 170 PIM SM traffic reduction in Global Ethernet environment

The devices on the edge of the Global Ethernet cloud are configured for IGMP snooping and PIM SM traffic snooping. Although this application uses multiple devices, the feature has the same requirements and works the same way as it does on a single device.

Configuration notes and limitations for PIM SM snooping

- PIM SM snooping applies only to PIM SM version 2 (PIM SM V2).
- PIM SM traffic snooping is supported in the Layer 2, base Layer 3, and full Layer 3 code.
- IGMP snooping must be enabled on the device that will be running PIM SM snooping. The PIM SM traffic snooping feature requires IGMP snooping.

NOTE

Use the passive mode of IGMP snooping instead of the active mode. The passive mode assumes that a router is sending group membership queries as well as join and prune messages on behalf of receivers. The active mode configures the device to send group membership queries.

- All the device ports connected to the source and receivers or routers must be in the same port-based VLAN.
- The PIM SM snooping feature assumes that the group source and the device are in different subnets and communicate through a router. The source must be in a different IP subnet than the receivers. A PIM SM router sends PIM join and prune messages on behalf of a multicast group receiver only when the router and the source are in different subnet. When the receiver and source are in the same subnet, they do not need the router in order to find one another. They find one another directly within the subnet.

The device forwards all IP multicast traffic by default. Once you enable IGMP snooping and PIM SM traffic snooping, the device initially blocks all PIM SM traffic instead of forwarding it. The device forwards PIM SM traffic to a receiver only when the device receives a join message from the receiver. Consequently, if the source and the downstream router are in the same subnet, and PIM SM traffic snooping is enabled, the device blocks the PIM SM traffic and never starts forwarding the traffic. This is because the device never receives a join message from the downstream router for the group. The downstream router and group find each other without a join message because they are in the same subnet.

NOTE

If the “route-only” feature is enabled on a Layer 3 Switch, PIM SM traffic snooping will not be supported.

IGMP snooping configuration

Configuring IGMP snooping on a Brocade device consists of the following global, VLAN-specific, and port-specific tasks:

Global IGMP snooping tasks

Perform the following global tasks:

- [“Configuring the IGMP V3 snooping software resource limits”](#)
- [“Enabling IGMP snooping globally on the device”](#)
- [“Configuring the global IGMP mode”](#)
- [“Configuring the global IGMP version”](#)
- [“Modifying the age interval for group membership entries”](#)
- [“Modifying the query interval \(active IGMP snooping mode only\)”](#)
- [“Modifying the maximum response time”](#)
- [“Configuring report control” \(rate limiting\)](#)
- [“Modifying the wait time before stopping traffic when receiving a leave message”](#)
- [“Modifying the multicast cache age time”](#)
- [“Enabling or disabling error and warning messages”](#)

VLAN-specific IGMP snooping tasks

Perform the following VLAN-specific tasks:

- “Configuring the IGMP mode for a VLAN” (active or passive)
- “Disabling IGMP snooping on a VLAN”
- “Configuring the IGMP version for a VLAN”
- “Configuring static router ports.”
- “Turning off static group proxy”
- “Enabling IGMP V3 membership tracking and fast leave for the VLAN”
- “Enabling fast leave for IGMP V2”
- “Enabling fast convergence”

Port-specific IGMP snooping tasks

Perform the following port-specific tasks:

- “Disabling transmission and receipt of IGMP packets on a port”
- “Configuring the IGMP version for individual ports in a VLAN”

Configuring the IGMP V3 snooping software resource limits

By default, FastIron X Series devices support up to 512 IGMP snooping multicast cache (mcache) entries and a maximum of 8K IGMP group addresses. If necessary, you can change the default values using the procedures in this section.

About IGMP snooping mcache entries and group addresses

An IGMP snooping group address entry is created when an IGMP join message is received for a group. An IGMP snooping mcache entry is created when data traffic is received for that group. Each mcache entry represents one data stream, and multiple mcache entries (up to 32) can share the same hardware (MAC) address entry. The egress port list for the mcache entry is obtained from the IGMP group address entry. If there is no existing IGMP group address entry when an mcache entry is created, data traffic for that multicast group is dropped in hardware. If there is an existing IGMP group address entry when an mcache is created, data traffic for that multicast group is switched in hardware.

Changing the maximum number of supported IGMP snooping mcache entries

When IGMP snooping is enabled, by default, the system supports up to 512 IGMP snooping mcache entries. If necessary, you can change the maximum number of IGMP snooping cache entries supported on the device. To do so, enter the **system-max igmp-snoop-mcache** command.

```
BrocadeBrocade(config)# system-max igmp-snoop-mcache 2000
```

Syntax: [no] **system-max igmp-snoop-mcache** <num>

where <num> is a value ranges from 256 through 8192. The default is 512.

Setting the maximum number of IGMP group addresses

When IGMP snooping is enabled, by default, FastIron X Series devices support up to 4096 of IGMP group addresses, and the configurable range is from 256 through 8192. The configured number is the upper limit of an expandable database. Client memberships exceeding the group limit are not processed. Enter the **system-max igmp-max-group-addr** command to define the maximum number of IGMP group addresses.

```
Brocade(config)# system-max igmp-max-group-addr 1600
```

Syntax: [no] **system-max igmp-max-group-addr** <num>

The <num> variable is a value ranging from 256 through 8192 and the default is 4096.

Enabling IGMP snooping globally on the device

When you globally enable IGMP snooping, you can specify IGMP V2 or IGMP V3. The **ip multicast version** command enables IGMP V3.

```
Brocade(config)# ip multicast version 3
```

Syntax: [no] **ip multicast version 2 | 3**

If you do not specify a version number, IGMP V2 is assumed.

Configuration notes for Layer 3 devices

- If Layer 3 multicast routing is enabled on your system, do not attempt to enable Layer 2 IGMP snooping. Layer 2 IGMP snooping is automatically enabled with Layer 3 multicast routing.
- If the “route-only” feature is enabled on the Layer 3 Switch, then IP multicast traffic reduction will not be supported.
- IGMP snooping is not supported on the default VLAN of Layer 3 Switches.

Configuring the IGMP mode

You can configure active or passive IGMP modes on the Brocade device. The default mode is passive. If you specify an IGMP mode for a VLAN, it overrides the global setting.

- **Active** - When active IGMP mode is enabled, a Brocade device actively sends out IGMP queries to identify multicast groups on the network, and makes entries in the IGMP table based on the group membership reports it receives.

NOTE

Routers in the network generally handle this operation. Use the active IGMP mode only when the device is in a stand-alone Layer 2 Switched network with no external IP multicast router attachments. In this case, enable the active IGMP mode on only one of the devices and leave the other devices configured for passive IGMP mode.

- **Passive** - When passive IGMP mode is enabled, it forwards reports to the router ports which receive queries. IGMP snooping in the passive mode does not send queries. However, it forwards queries to the entire VLAN.

Configuring the global IGMP mode

To globally set the IGMP mode to active, enter the following command.

```
Brocade(config)# ip multicast active
```

Syntax: [no] ip multicast [active | passive]

If you do not enter either *active* or *passive*, the passive mode is assumed.

Configuring the IGMP mode for a VLAN

If you specify an IGMP mode for a VLAN, it overrides the global setting.

To set the IGMP mode for VLAN 20 to active, enter the following commands.

```
Brocade(config)# vlan 20
Brocade(config-vlan-20)# multicast active
```

Syntax: [no] multicast active | passive

Configuring the IGMP version

Use the procedures in this section to specify the IGMP version.

Configuring the global IGMP version

To globally specify IGMP V2 or IGMP V3, refer to [“Enabling IGMP snooping globally on the device”](#) on page 1469.

Configuring the IGMP version for a VLAN

You can specify the IGMP version for a VLAN. For example, the following commands configure VLAN 20 to use IGMP V3.

```
Brocade(config)# vlan 20
Brocade(config-vlan-20)# multicast version 3
```

Syntax: [no] multicast version 2 | 3

If no IGMP version is specified, then the globally-configured IGMP version is used. If an IGMP version is specified for individual ports, those ports use that version, instead of the VLAN version.

Configuring the IGMP version for individual ports in a VLAN

You can specify the IGMP version for individual ports in a VLAN. For example, the following commands configure ports 4, 5, and 6 to use IGMP V3. The other ports either use the IGMP version specified with the multicast version command, or the globally-configured IGMP version.

```
Brocade(config)# vlan 20
Brocade(config-vlan-20)# multicast port-version 3 ethernet 2/4 to 2/6
```

Syntax: [no] multicast port-version 2 | 3 ethernet <port> [ethernet <port> | to <port>]

Specify the <port> variable in one of the following formats:

- FSX 800 and FSX 1600 chassis devices – <slotnum/portnum>
- FESX compact switches – <portnum>

To specify a list of ports, enter each port as **ethernet <port>** followed by a space. For example, **ethernet 1/24 ethernet 6/24 ethernet 8/17**

To specify a range of ports, enter the first port in the range as **ethernet <port>** followed by the last port in the range. For example, **ethernet 1/1 to 1/8**.

You can combine lists and ranges in the same command. For example: **enable ethernet 1/1 to 1/8 ethernet 1/24 ethernet 6/24 ethernet 8/17**.

Disabling IGMP snooping on a VLAN

When IGMP snooping is enabled globally, you can still disable it for a specific VLAN. For example, the following commands cause IGMP snooping to be disabled for VLAN 20. This setting overrides the global setting.

```
Brocade(config)# vlan 20
Brocade(config-vlan-20)# multicast disable-multicast-snoop
```

Syntax: [no] multicast disable-multicast-snoop

Disabling transmission and receipt of IGMP packets on a port

When a VLAN is snooping-enabled, all IGMP packets are trapped to the CPU without hardware VLAN flooding. The CPU can block IGMP packets to and from a multicast-disabled port, and does not add it to the output interfaces of hardware resources. This prevents the disabled port from receiving multicast traffic. However, if static groups to the entire VLAN are defined, the traffic from these groups is VLAN flooded, including to disabled ports. Traffic from disabled ports cannot be blocked in hardware, and is switched in the same way as traffic from enabled ports.

This command has no effect on a VLAN that is not snooping-enabled because all multicast traffic is VLAN flooded.

To disable transmission and receipt of IGMP packets on a port, enter the following commands.

```
Brocade(config)# interface ethernet 3
Brocade(config-if-e1000-3)# ip-multicast-disable
```

The above commands disable IGMP snooping on port 1/5 but does not affect the state of IGMP on other ports.

Syntax: [no] ip-multicast-disable

Modifying the age interval for group membership entries

When the device receives a group membership report, it makes an entry for that group in the IGMP group table. The age interval specifies how long the entry can remain in the table before the device receives another group membership report. When multiple devices connect together, all devices must be configured for the same age interval, which must be at least twice the length of the query interval, so that missing one report won't stop traffic. Non-querier age intervals must be the same as the age interval of the querier.

To modify the age interval, enter the following command.

```
Brocade(config)# ip multicast age-interval 280
```

Syntax: [no] ip multicast age-interval <interval>

The <interval> parameter specifies the aging time. You can specify a value from 20 through 7200 seconds. The default is 260 seconds.

Modifying the query interval (active IGMP snooping mode only)

If IP multicast traffic reduction is set to active mode, you can modify the query interval to specify how often the device sends general queries. When multiple queriers connect together, they must all be configured with the same query interval.

To modify the query interval, enter the following command.

```
Brocade(config)# ip multicast query-interval 120
```

Syntax: [no] ip multicast query-interval <interval>

The <interval> parameter specifies the time between queries. You can specify a value from 10 through 3600 seconds. The default is 125 seconds.

Modifying the maximum response time

The maximum response time is the number of seconds that a client can wait before responding to a query sent by the switch.

To change the maximum response time, enter the following command.

```
Brocade(config)# ip multicast max-response-time 5
```

Syntax: [no] ip multicast max-response-time <interval>

For <interval>, enter a value from 1 through 10 seconds. The default is 10 seconds.

Configuring report control

A device in passive mode forwards reports and leave messages from clients to the upstream router ports that are receiving queries.

You can configure report control to rate-limit report forwarding within the same group to no more than once every 10 seconds. This rate-limiting does not apply to the first report answering a group-specific query.

NOTE

This feature applies to IGMP V2 only. The leave messages are not rate limited.

IGMP V2 membership reports of the same group from different clients are considered to be the same and are rate-limited.

Use the **ip multicast report-control** command to alleviate report storms from many clients answering the upstream router query.

```
Brocade(config)# ip multicast report-control
```

Syntax: [no] ip multicast report-control

The original command, **ip igmp-report-control**, has been renamed to **ip multicast report-control**. The original command is still accepted; however, it is renamed when you issue a **show configuration** command.

Modifying the wait time before stopping traffic when receiving a leave message

You can define the wait time before stopping traffic to a port when a leave message is received. The device sends group-specific queries once per second to ask if any client in the same port still needs this group. Due to internal timer granularity, the actual wait time is between n and $(n+1)$ seconds (n is the configured value).

```
Brocade(config)# ip multicast leave-wait-time 1
```

Syntax: [no] **ip multicast leave-wait-time** *<num>*

<num> is the number of seconds from 1 through 5. The default is 2 seconds.

Modifying the multicast cache age time

You can set the time for an mcache to age out when it does not receive traffic. The traffic is hardware switched. One minute before aging out an mcache, the device mirrors a packet of this mcache to CPU to reset the age. If no data traffic arrives within one minute, this mcache is deleted. A lower value quickly removes resources consumed by idle streams, but it mirrors packets to CPU often. A higher value is recommended only data streams are continually arriving.

```
Brocade(config)# ip multicast mcache-age 180
```

Syntax: [no] **ip multicast mcache-age** *<num>*

<num> is the number of seconds from 60 through 3600. The default is 60 seconds.

Enabling or disabling error and warning messages

The device prints error or warning messages when it runs out of software resources or when it receives packets with the wrong checksum or groups. These messages are rate-limited. You can turn off these messages by entering the following command.

```
Brocade(config)# ip multicast verbose-off
```

Syntax: [no] **ip multicast verbose-off**

Configuring static router ports

The Brocade device forwards all multicast control and data packets to router ports which receive queries. Although router ports are learned, you can force multicast traffic to specified ports even though these ports never receive queries. To configure static router ports, enter the following commands.

```
Brocade(config)#vlan 70
Brocade(config-vlan-70)# multicast router-port ethernet 4 to 5 ethernet 8
```

Syntax: [no] **multicast router-port ethernet** *<port>* [**ethernet** *<port>* | **to** *<port>*]

Specify the `<port>` variable in one of the following formats:

- FSX 800 and FSX 1600 chassis devices – `<slotnum/portnum>`
- FESX compact switches – `<portnum>`

To specify a list of ports, enter each port as **ethernet** `<port>` followed by a space. For example, **ethernet 1/24 ethernet 6/24 ethernet 8/17**

To specify a range of ports, enter the first port in the range as **ethernet** `<port>` followed by the last port in the range. For example, **ethernet 1/1 to 1/8**.

You can combine lists and ranges in the same command. For example: **enable ethernet 1/1 to 1/8 ethernet 1/24 ethernet 6/24 ethernet 8/17**.

Turning off static group proxy

If a device has been configured for static groups, it acts as a proxy and sends membership reports for the static groups when it receives general or group-specific queries. When a static group configuration is removed, it is deleted from the active group table immediately. However, leave messages are not sent to the querier, and the querier must age out the group. Proxy activity can be turned off. The default is on. To turn proxy activity off for VLAN 20, enter the following commands.

```
Brocade(config)# vlan 20
Brocade(config-vlan-20)# multicast proxy-off
```

Syntax: `[no] multicast proxy-off`

Enabling IGMP V3 membership tracking and fast leave for the VLAN

IGMP V3 gives clients membership tracking and fast leave capability. In IGMP V2, only one client on an interface needs to respond to a router's queries. This can leave some clients invisible to the router, making it impossible to track the membership of all clients in a group. When a client leaves the group, the device sends group-specific queries to the interface to see if other clients on that interface need the data stream of the client who is leaving. If no client responds, the device waits a few seconds before it stops the traffic. You can configure the wait time using the **ip multicast leave-wait-time** command.

IGMP V3 requires every client to respond to queries, allowing the device to track all clients. When tracking is enabled, and an IGMP V3 client sends a leave message and there is no other client, the device immediately stops forwarding traffic to the interface. This feature requires the entire VLAN be configured for IGMP V3 with no IGMP V2 clients. If a client does not send a report during the specified group membership time (the default is 260 seconds), that client is removed from the tracking list.

Every group on a physical port keeps its own tracking record. However, it can only track group membership; it cannot track by (source, group). For example, Client A and Client B belong to group1 but each receives traffic streams from different sources. Client A receives a stream from (source_1, group1) and Client B receives a stream from (source_2, group1). The device still waits for the configured leave-wait-time before it stops the traffic because these two clients are in the same group. If the clients are in different groups, then the waiting period is not applied and traffic is stopped immediately.

To enable the tracking and fast leave feature for VLAN 20, enter the following commands.

```
Brocade(config)# vlan 20
Brocade(config-vlan-20)# multicast tracking
```

Syntax: [no] multicast tracking

The membership tracking and fast leave features are supported for IGMP V3 only. If any port or any client is not configured for IGMP V3, then the multicast tracking command is ignored.

Enabling fast leave for IGMP V2

When a device receives an IGMP V2 leave message, it sends out multiple group-specific queries. If no other client replies within the waiting period, the device stops forwarding traffic. When fast-leave-v2 is configured, and when the device receives a leave message, it immediately stops forwarding to that port. The device does not send group specific-queries. You must ensure that no snooping-enabled ports have multiple clients. When two devices connect together, the querier must not be configured for fast-leave-v2, because the port might have multiple clients through the non-querier. The number of queries, and the waiting period (in seconds) can be configured using the **ip multicast leave-wait-time** command. The default is 2 seconds.

To configure fast leave for IGMP V2, enter the following commands.

```
Brocade(config)# vlan 20
Brocade(config-vlan-20)# multicast fast-leave-v2
```

Syntax: [no] multicast fast-leave-v2

Enabling fast convergence

In addition to sending periodic general queries, an active device sends general queries when it detects a new port. However, because the device does not recognize the other device's port up event, multicast traffic might still require up to the query-interval time to resume after a topology change. Fast convergence allows the device to listen to topology change events in Layer 2 protocols such as spanning tree, and then send general queries to shorten the convergence time.

If the Layer 2 protocol cannot detect a topology change, fast convergence may not work in some cases. For example, if the direct connection between two devices switches from one interface to another, the rapid spanning tree protocol (802.1w) considers this optimization, rather than a topology change. In this example, other devices will not receive topology change notifications, and will be unable to send queries to speed up the convergence. Fast convergence works well with the regular spanning tree protocol in this case.

To enable fast-convergence, enter the following commands.

```
Brocade(config)# vlan 70
Brocade(config-vlan-70)# multicast fast-convergence
```

Syntax: multicast fast-convergence

PIM SM snooping configuration

Configuring PIM SM snooping on a Brocade device consists of the following global and VLAN-specific tasks.

Global PIM SM snooping task

Perform the following global tasks:

- [“Enabling or disabling PIM SM snooping”](#)

VLAN-specific PIM SM snooping tasks

Perform the following VLAN-specific tasks:

- [“Enabling PIM SM snooping on a VLAN”](#)
- [“Disabling PIM SM snooping on a VLAN”](#)

Enabling or disabling PIM SM snooping

Use PIM SM snooping only in topologies where multiple PIM sparse routers connect through a device. PIM SM snooping does not work on a PIM dense mode router which does not send join messages and traffic to PIM dense ports is stopped. A PIM SM snooping-enabled device displays a warning if it receives PIM dense join or prune messages.

To enable PIM sparse snooping globally, enter the **ip pimsm-snooping** command.

```
Brocade(config)# ip pimsm-snooping
```

This command enables PIM SM traffic snooping. The PIM SM traffic snooping feature assumes that the network has routers that are running PIM SM.

NOTE

The device must be in passive mode before it can be configured for PIM SM snooping.

To disable the feature, enter the **no ip pimsm-snooping** command.

```
Brocade(config)# no ip pimsm-snooping
```

If you also want to disable IP multicast traffic reduction, enter the **no ip multicast** command.

```
Brocade(config)# no ip multicast
```

Syntax: [no]ip pimsm-snooping

Enabling PIM SM snooping on a VLAN

You can enable PIM SM snooping for a specific VLAN. For example, the following commands enable PIM SM snooping on VLAN 20.

```
Brocade(config)# vlan 20
Brocade(config-vlan-20)# multicast pimsm-snooping
```

Syntax: [no] multicast pimsm-snooping

Disabling PIM SM snooping on a VLAN

When PIM SM snooping is enabled globally, you can still disable it for a specific VLAN. For example, the following commands disable PIM SM snooping for VLAN 20. This setting overrides the global setting.

```
Brocade(config)# vlan 20
Brocade(config-vlan-20)# multicast disable-pimsm-snoop
```

Syntax: [no] multicast disable-pimsm-snoop

IGMP snooping show commands

This section describes the **show** commands for IGMP snooping.

Displaying the IGMP snooping configuration

To display the global IGMP snooping configuration, enter the **show ip multicast** command at any level of the CLI.

```
Brocade# show ip multicast
Summary of all vlans. Please use "sh ip mu vlan <vlan-id>" for details
Version=2, Intervals: Query=125, Group Age=260, Max Resp=10, Other Qr=260
VL10: cfg V3, vlan cfg passive, , pimsm (vlan cfg), 1 grp, 0 (SG) cache, no rtr
port
```

To display the IGMP snooping information for a specific VLAN, enter the following command.

```
Brocade# show ip multicast vlan 10
Version=3, Intervals: Query=10, Group Age=260, Max Resp=10, Other Qr=30
VL10: cfg V3, vlan cfg passive, , pimsm (vlan cfg), 3 grp, 1 (SG) cache, no rtr
port,
  e2      has      3 groups, non-QR (passive), default V3
  **** Warning! has V2 client (life=240),
    group: 239.0.0.3, life = 240
    group: 224.1.1.2, life = 240
    group: 224.1.1.1, life = 240

  e4      has      0 groups, non-QR (passive), default V3
```

Syntax: show ip multicast vlan [<vlan-id>]

If you do not specify a <vlan-id>, information for all VLANs is displayed.

The following table describes the information displayed by the **show ip multicast vlan** command.

Field	Description
Version	The global IGMP version. In this example, the device is configured for IGMP version 2.
Query	How often a querier sends a general query on the interface. In this example, the general queries are sent every 125 seconds.
Group Age	The number of seconds membership groups can be members of this group before aging out.
Max Resp	The maximum number of seconds a client waits before replying to a query.

Field	Description
Other Qr	How long it took a switch with a lower IP address to become a new querier. This value is 2 x Query + Max Resp.
cfg	The IGMP version for the specified VLAN. In this example, VL10: cfg V3 indicates that VLAN 10 is configured for IGMP V3.
vlan cfg	The IGMP configuration mode, which is either passive or active.
pimsm	Indicates that PIM SM is enabled on the VLAN.
rtr port	The router ports, which are the ports receiving queries.

Displaying IGMP snooping errors

To display information about possible IGMP errors, enter the **show ip multicast error** command.

```
Brocade# show ip multicast error
snoop SW processed pkt: 173, up-time 160 sec
```

Syntax: **show ip multicast error**

The following table describes the output from the **show ip multicast error** command.

Field	Description
SW processed pkt	The number of multicast packets processed by IGMP snooping.
up-time	The time since the IGMP snooping is enabled.

Displaying IGMP group information

To display information about IGMP groups, enter the **show ip multicast group** command.

```
Brocade# show ip multicast group
p-:physical, ST:static, QR:querier, EX:exclude, IN:include, Y:yes, N:no
VL70 : 3 groups, 4 group-port, tracking_enabled
      group      p-port  ST    QR    life mode  source
1      224.1.1.2    1/33   no   yes   120  EX    0
2      224.1.1.1    1/33   no   yes   120  EX    0
3      226.1.1.1    1/35   yes  yes   100  EX    0
4      226.1.1.1    1/33   yes  yes   100  EX    0
```

In this example, an IGMP V2 group is in EXCLUDE mode with a source of 0. The group only excludes traffic from the 0 (zero) source list, which actually means that all traffic sources are included.

To display detailed IGMP group information for a specific group, enter the **show ip multicast group detail** command.

```

Brocade# show ip multicast group 226.1.1.1 detail
Display group 226.1.1.1 in all interfaces in details.
p-:physical, ST:static, QR:querier, EX:exclude, IN:include, Y:yes, N:no
VL70 : 1 groups, 2 group-port, tracking_enabled
      group      p-port  ST    QR    life mode    source
1      226.1.1.1    1/35   yes   yes   120  EX      0
      group: 226.1.1.1, EX, permit 0 (source, life):
      life=120, deny 0:
      group      p-port  ST    QR    life mode    source
2      226.1.1.1    1/33   yes   yes   120  EX      0
      group: 226.1.1.1, EX, permit 0 (source, life):
      life=120, deny 0:

```

If the tracking and fast leave features are enabled, you can display the list of clients that belong to a particular group by entering the following command.

```

Brocade# show ip multicast group 224.1.1.1 tracking
Display group 224.1.1.1 in all interfaces with tracking enabled.
p-:physical, ST:static, QR:querier, EX:exclude, IN:include, Y:yes, N:no
VL70 : 1 groups, 1 group-port, tracking_enabled
      group      p-port  ST    QR    life mode    source
*** Note: has 1 static groups to the entire vlan, not displayed here
1      224.1.1.1    1/33   no    yes   100  EX      0
      receive reports from 1 clients: (age)
      (2.2.100.2 60)

```

Syntax: `show ip multicast group [<group-address> [detail] [tracking]]`

If you want a report for a specific multicast group, enter that group's address for `<group-address>`.

Enter detail to display the source list of a specific VLAN.

Enter tracking for information on interfaces that have tracking enabled.

The following table describes the information displayed by the `show ip multicast group` command.

Field	Description
group	The address of the group (destination address in this case, 224.1.1.1)
p-port	The physical port on which the group membership was received.
ST	Yes indicates that the IGMP group was configured as a static group; No means the address was learned from reports.
QR	Yes means the port is a querier port; No means it is not. A port becomes a non-querier port when it receives a query from a source with a lower source IP address than the device.
life	The number of seconds the group can remain in EXCLUDE mode. An EXCLUDE mode changes to INCLUDE mode if it does not receive an "IS_EX" or "TO_EX" message during a certain period of time. The default is 260 seconds. There is no life displayed in INCLUDE mode.
mode	Indicates current mode of the interface: INCLUDE or EXCLUDE. If the interface is in INCLUDE mode, it admits traffic only from the source list. If an interface is in EXCLUDE mode, it denies traffic from the source list and accepts the rest.
source	Identifies the source list that will be included or excluded on the interface. For example, if an IGMP V2 group is in EXCLUDE mode with a source of 0, the group excludes traffic from the 0 (zero) source list, which actually means that all traffic sources are included.

Displaying IGMP snooping mcache information

The IGMP snooping mcache contains multicast forwarding information for VLANs. To display information in the multicast forwarding mcache, enter the **show ip multicast mcache** command.

```
Brocade# show ip multicast mcache
Example: (S G) cnt=: cnt is number of SW processed packets
        OIF: e1/22 TR(1/32,1/33), TR is trunk, e1/32 primary, e1/33 output
        vlan 10, 1 caches. use 1 VIDX
1      (10.10.10.2 239.0.0.3) cnt=0
        OIF: tag e2
        age=2s up-time=2s change=2s vidx=8191 (ref-cnt=1)
```

Syntax: show ip multicast mcache

The following table describes the output of the **show ip multicast mcache** command.

Field	Description
(source group)	Source and group addresses of this data stream. (* group) means match group only; (source group) means match both.
cnt	The number of packets processed in software. Packets are switched in hardware, which increases this number slowly.
OIF	The output interfaces. If entire vlan is displayed, this indicates that static groups apply to the entire VLAN.
age	The mcache age. The mcache will be reset to 0 if traffic continues to arrive, otherwise the mcache will be aged out when it reaches the time defined by the ip multicast mcache-age command.
uptime	The up time of this mcache in seconds.
vidx	Vidx specifies output port list index. Range is from 4096 through 8191
ref-cnt	The vidx is shared among mcaches having the same output interfaces. Ref-cnt indicates the number of mcaches using this vidx.

Displaying software resource usage for VLANs

To display information about the software resources used, enter the **show ip multicast resource** command.

```
Brocade# show ip multicast resource
          alloc in-use avail get-fail    limit  get-mem  size init
igmp group      256     1    255         0   32000      1    16  256
igmp phy port   1024     1   1023         0  200000      1    22 1024
... entries deleted ...
snoop mcache entry  128     2    126         0    8192      3    56  128
total pool memory 109056 bytes
has total 2 forwarding hash
VIDX sharing hash : size=2      anchor=997  2nd-hash=no  fast-trav=no
Available vidx: 4060. IGMP/MLD use 2
```

Syntax: show ip multicast resource

The following table describes the output displayed by the **show ip multicast resource** command.

Field	Description
alloc	The allocated number of units.
in-use	The number of units which are currently being used.
avail	The number of available units.
get-fail	This displays the number of resource failures. NOTE: It is important to pay attention to this field.
limit	The upper limit of this expandable field. The limit of <code>multicast group</code> is configured by the <code>system-max igmp-max-group-addr</code> command. The limit of <code>snoop mcache entry</code> is configured by the <code>system-max multicast-snoop-mcache</code> command.
get-mem	The number of memory allocation. This number must continue to increase.
size	The size of a unit (in bytes).
init	The initial allocated amount of memory. More memory may be allocated if resources run out.
Available vidx	The output interface (OIF) port mask used by mcache. The entire device has a maximum of 4096 vidx. Different mcaches with the same OIF share the same vidx. If vidx is not available, the stream cannot be hardware-switched.

Displaying the status of IGMP snooping traffic

To display status information for IGMP snooping traffic, enter the **show ip multicast traffic** command.

```

Brocade# show ip multicast traffic
IGMP snooping: Total Recv: 22, Xmit: 26
Q: query, Qry: general Q, G-Qry: group Q, GSQry: group-source Q, Mbr: member
Recv      QryV2      QryV3      G-Qry      GSQry      MbrV2      MbrV3      Leave
VL1        0          0          0          0          4          0          0
VL70       18          0          0          0          0          0          0
Recv      IsIN      IsEX      ToIN      ToEX      ALLOW      BLOCK      Pkt-Err
VL1        0          4          0          0          0          0          0
VL70       0          0          0          0          0          0          0

Send      QryV2      QryV3      G-Qry      GSQry      MbrV2      MbrV3
VL1        0          0          8          0          0          0
VL70       0          0          0          0          0          18
VL70  pimsm-snooping, Hello: 12, Join/Prune: 9

```

Syntax: show ip multicast traffic

The following table describes the information displayed by the **show ip multicast traffic** command.

Field	Description
Q	Query
Qry	General Query
QryV2	Number of general IGMP V2 queries received or sent.
QryV3	Number of general IGMP V3 queries received or sent.
G-Qry	Number of group-specific queries received or sent.

Field	Description
GSQry	Number of group source-specific queries received or sent.
Mbr	The membership report.
MbrV2	The IGMP V2 membership report.
MbrV3	The IGMP V3 membership report.
IsIN	Number of source addresses that were included in the traffic.
IsEX	Number of source addresses that were excluded in the traffic.
ToIN	Number of times the interface mode changed from EXCLUDE to INCLUDE.
ToEX	Number of times the interface mode changed from INCLUDE to EXCLUDE.
ALLO	Number of times that additional source addresses were allowed on the interface.
BLK	Number of times that sources were removed from an interface.
Pkt-Err	Number of packets having errors, such as checksum.
Pism-snooping hello, join, prune	Number of PIM sparse hello, join, and prune packets

Displaying querier information

You can use the **show ip multicast vlan** command to display the querier information for a VLAN. This command displays the VLAN interface status and if there is any other querier present with the lowest IP address. The following list provides the combinations of querier possibilities:

- Active Interface with no other querier present
- Passive Interface with no other querier present
- Active Interface with other querier present
- Passive Interface with other querier present

Displaying the active interface with no other querier present

The following example shows the output in which the VLAN interface is active and no other querier is present with the lowest IP address.

```
Brocade# show ip multicast vlan 10
Version=2, Intervals: Query=125, Group Age=260, Max Resp=10, Other Qr=260
VL10: dft V2, vlan cfg active, 0 grp, 0 (*G) cache, no rtr port,

    1/1/16 has    0 groups,
This interface is Querier
default V2

    1/1/24 has    0 groups,
This interface is Querier
default V2

    2/1/16 has    0 groups,
This interface is Querier
default V2

    2/1/24 has    0 groups,
This interface is Querier
```

```

default V2

    3/1/1   has    0 groups,
This interface is Querier
default V2

    3/1/4   has    0 groups,
This interface is Querier
default V2

```

Syntax: `show ip multicast vlan <vlan-id>`

If you do not specify a <vlan-id>, information for all VLANs is displayed.

Displaying the passive interface with no other querier present

The following example shows the output in which the VLAN interface is passive and no other querier is present with the lowest IP address.

```

Brocade# show ip multicast vlan 10
Version=2, Intervals: Query=125, Group Age=260, Max Resp=10, Other Qr=260

VL10: dft V2, vlan cfg passive, 0 grp, 0 (*G) cache, no rtr port,

    1/1/16  has    0 groups,
This interface is non-Querier (passive)
default V2

    1/1/24  has    0 groups,
This interface is non-Querier (passive)
default V2

    2/1/16  has    0 groups,
This interface is non-Querier (passive)
default V2

    2/1/24  has    0 groups,
This interface is non-Querier (passive)
default V2

    3/1/1   has    0 groups,
This interface is non-Querier (passive)
default V2

    3/1/4   has    0 groups,
This interface is non-Querier (passive)
default V2

```

Displaying the active Interface with other querier present

The following example shows the output in which the VLAN interface is active and another querier is present with the lowest IP address.

```

Brocade# show ip multicast vlan 10
Version=2, Intervals: Query=125, Group Age=260, Max Resp=10, Other Qr=260

VL10: dft V2, vlan cfg active, 7 grp, 6 (*G) cache, rtr ports,
      router ports: 2/1/24(260) 5.5.5.5, 3/1/4(260) 8.8.8.8,

```

IGMP snooping show commands

```
1/1/16 has 4 groups,
This interface is Querier
default V2
  group: 226.6.6.6, life = 240
  group: 228.8.8.8, life = 240
  group: 230.0.0.0, life = 240
  group: 224.4.4.4, life = 240

1/1/24 has 1 groups,
This interface is Querier
default V2
  group: 228.8.8.8, life = 240

2/1/16 has 4 groups,
This interface is Querier
default V2
  group: 226.6.6.6, life = 240
  group: 228.8.8.8, life = 240
  group: 230.0.0.0, life = 240
  group: 224.4.4.4, life = 240

2/1/24 has 2 groups,
This interface is non-Querier
Querier is 5.5.5.5
Age is 0
Max response time is 100
default V2
  **** Warning! has V3 (age=0) nbrs
  group: 234.4.4.4, life = 260
  group: 226.6.6.6, life = 260

3/1/1 has 4 groups,
This interface is Querier
default V2
  group: 238.8.8.8, life = 260
  group: 228.8.8.8, life = 260
  group: 230.0.0.0, life = 260
  group: 224.4.4.4, life = 260

3/1/4 has 1 groups,
This interface is non-Querier
Querier is 8.8.8.8
Age is 0
Max response time is 100
default V2
  **** Warning! has V3 (age=0) nbrs
  group: 236.6.6.6, life = 260
```

Displaying the passive interface with other querier present

The following example shows the output in which the VLAN interface is passive and another querier is present with the lowest IP address.

```
Brocade# show ip multicast vlan 10
Version=2, Intervals: Query=125, Group Age=260, Max Resp=10, Other Qr=260

VL10: dft V2, vlan cfg passive, 7 grp, 6 (*G) cache, rtr ports,
  router ports: 2/1/24(260) 5.5.5.5, 3/1/4(260) 8.8.8.8,
```

```

1/1/16 has 4 groups,
This interface is non-Querier (passive)
default V2
  group: 226.6.6.6, life = 260
  group: 228.8.8.8, life = 260
  group: 230.0.0.0, life = 260
  group: 224.4.4.4, life = 260

1/1/24 has 1 groups,
This interface is non-Querier (passive)
default V2
  group: 228.8.8.8, life = 260

2/1/16 has 4 groups,
This interface is non-Querier (passive)
default V2
  group: 226.6.6.6, life = 260
  group: 228.8.8.8, life = 260
  group: 230.0.0.0, life = 260
  group: 224.4.4.4, life = 260

2/1/24 has 2 groups,
This interface is non-Querier (passive)
Querier is 5.5.5.5
Age is 0
Max response time is 100
default V2
  **** Warning! has V3 (age=0) nbrs
  group: 234.4.4.4, life = 260
  group: 226.6.6.6, life = 260

```

PIM SM snooping show commands

This section shows how to display information about PIM SM snooping, including:

- [“Displaying PIM SM snooping information”](#)
- [“Displaying PIM SM snooping information on a Layer 2 switch”](#)
- [“Displaying PIM SM snooping information for a specific group or source group pair”](#)

Displaying PIM SM snooping information

To display PIM SM snooping information, enter the **show ip multicast pimsm-snooping** command.

```
Brocade# show ip multicast pimsm-snooping
vlan 1, has 2 caches.
1    (* 230.1.1.1) has 1 pim join ports out of 1 OIF
    1 (age=60)
    1 has 1 src: 20.20.20.66(60)
2    (* 230.2.2.2) has 1 pim join ports out of 1 OIF
    1 (age=60)
    1 has 1 src: 20.20.20.66(60)
```

This output shows the number of PIM join OIF out of the total OIF. The join or prune messages are source-specific. In this case, If the mcache is in (* G), the display function will also print the traffic source information.

Syntax: **show ip multicast pimsm-snooping** [*<vlan-id>*]

Use the *<vlan-id>* parameter to display PIM SM snooping information for a specific VLAN.

Displaying PIM SM snooping information on a Layer 2 switch

You can display PIM SM snooping information for all groups by entering the following command at any level of the CLI on a Layer 2 Switch.

```

Brocade# show ip multicast pimsm-snooping vlan 100
VLAN ID 100, total 3 entries
PIMSM Neighbor list:
    1.100.100.12      : 3/3 expire 120 s
    1.100.100.10      : 3/2 expire 170 s
    1.100.100.7       : 3/1 expire 160 s
1   Group: 224.0.1.22, fid 08ac, NO cam
    Forwarding Port: 3/3
    PIMv2 Group Port: 3/3
    (Source, Port) list: 1 entries
2   Group: 239.255.162.2, fid 08aa, cam 8
    Forwarding Port: 3/1 3/2
    PIMv2 Group Port: 3/1 3/2
    (Source, Port) list: 3 entries
3   Group: 239.255.163.2, fid 08a9, cam 10
    Forwarding Port: 3/1 3/2
    PIMv2 Group Port: 3/1 3/2
    (Source, Port) list: 3 entries
VLAN ID 4008, total 0 entries
PIMSM Neighbor list:

```

Syntax: `show ip mulitcast pimsm-snooping vlan <vlan-id>`

Enter the ID of the VLAN for the **vlan** *<vlan-id>* parameter.

If you want to display PIM SM snooping information for one source or one group, enter a command as in the following example. The command also displays the (source, port) list of the group.

```

Brocade# show ip multicst pimsm-snooping 239.255.163.2
Show pimsm snooping group 239.255.163.2 in all vlan
VLAN ID 100
  Group: 239.255.163.2, fid 08a9, cam 10
    Forwarding Port: 3/1 3/2
    PIMv2 Group Port: 3/1 3/2
    (Source, Port) list: 3 entries
      1   192.168.176.44, age=0, port: 3/2
      2   158.158.158.158, age=0, port: 3/1
      3   1.1.7.1, age=0, port: 3/2

```

Syntax: `show ip multicst pimsm-snooping <group-address> | <source-address>`

If the address you entered is within the range of source addresses, then the router treats it as the source address. Likewise, if the address falls in the range of group addresses, then the router assumes that you are requesting a report for that group.

The following table describes the information displayed by the **show ip multicast pimsm-snooping** command.

Field	Description
VLAN ID	The port-based VLAN to which the information listed below apply and the number of members in the VLAN.
PIM SM Neighbor list	The PIM SM routers that are attached to the Layer 2 Switch ports. The value following “expires” indicates how many seconds the Layer 2 Switch will wait for a hello message from the neighbor before determining that the neighbor is no longer present and removing the neighbor from the list.

Field	Description
Multicast Group	The IP address of the multicast group. NOTE: The fid and camindex values are used by Brocade Technical Support for troubleshooting.
Forwarding Port	The ports attached to the group receivers. A port is listed here when it receives a join message for the group, an IGMP membership report for the group, or both.
PIMv2 Group Port	The ports on which the Layer 2 Switch has received PIM SM join messages for the group.
Source, Port list	The IP address of each PIM SM source and the Layer 2 Switch ports connected to the receivers of the source.

Displaying PIM SM snooping information for a specific group or source group pair

To display PIM SM snooping information for a specific group, enter the following command at any level of the CLI.

```
Brocade# show ip multicast pimsm-snooping 230.1.1.1
Show pimsm snooping group 230.1.1.1 in all vlans
vlan 10, has 2 caches.
1 (*230.1.1.1) has 1 pim join ports out of 1 OIF
  1(age=120)
    1 has 1 src:20.20.20.66(120)
```

To display PIM SM snooping information for a specific (source, group) pair, enter the following command at any level of the CLI.

```
Brocade# show ip multicast pimsm-snooping 230.2.2.2 20.20.20.66
Show pimsm snooping source 20.20.20.66, group 230.2.2.2 in all vlans
vlan 10: (*230.2.2.2) has 1 pim join ports out of 2 OIF
  1(age=0)
    1 has 1 src:20.20.20.66(0)
```

Syntax: `show ip multicast pimsm-snooping <group-address> [<source-ip-address>]`

The Brocade device determines which address is the group address and which one is the source address based on the ranges that the address fall into. If the address is within the range of source addresses, then the router treats it as the source address. Likewise, if the address falls in the range of group addresses, then the router assumes it is a group address.

The following table describes the information displayed by the **show ip multicast pimsm-snooping** command.

Field	Description
vlan	The VLAN membership ID of the source.
port	The port on which the source is sending traffic. In this example, the port number is 1.
age	The age of the port, in seconds.
src	The source address and age. The age (number of seconds) is indicated in brackets immediately following the source.

Clear commands for IGMP snooping

The clear IGMP snooping commands must be used only in troubleshooting conditions, or to recover from errors.

Clearing the IGMP mcache

To clear the mcache on all VLANs, enter the **clear ip multicast mcache** command.

```
Brocade# clear ip multicast mcache
```

Syntax: clear ip multicast mcache

Clearing the mcache on a specific VLAN

To clear the mcache on a specific VLAN, enter the following command.

```
Brocade# clear ip multicast vlan 10 mcache
```

Syntax: clear ip multicast vlan <vlan-id> mcache

The <vlan-id> parameter specifies the specific VLAN in which the mcache needs to be cleared.

Clearing traffic on a specific VLAN

To clear the traffic counters on a specific VLAN, enter the following command.

```
Brocade# clear ip multicast vlan 10 traffic
```

Syntax: clear ip multicast vlan <vlan-id> traffic

The <vlan-id> parameter specifies the specific VLAN in which traffic counters needs to be cleared.

Clearing IGMP counters on VLANs

To clear IGMP snooping on error and traffic counters for all VLANs, enter the **clear ip multicast counters** command.

```
Brocade# clear ip multicast counters
```

Syntax: clear ip multicast counters

Clear commands for IGMP snooping

IP Multicast Traffic Reduction for FastIron WS and Brocade FCX and ICX Switches

Table 252 lists the individual Brocade FastIron switches and the IP multicast traffic reduction features they support. These features are supported in the Layer 2, base Layer 3, edge Layer 3, and full Layer 3 software images, except where explicitly noted.

TABLE 252 Supported IP multicast reduction features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
IGMP v1/v2 Snooping Global	For details about IP multicast traffic reduction on FastIron X Series switches, refer to “IGMP snooping configuration” on page 1467.	Yes	Yes	Yes	Yes
IGMP v3 Snooping Global		Yes (S,G)	Yes (S,G)	Yes (S,G)	Yes
IGMP v1/v2/v3 Snooping per VLAN		Yes	Yes	Yes	Yes
IGMP v2/v3 Fast Leave (membership tracking)		Yes	Yes	Yes	Yes
PIM-SM V2 Snooping		Yes	Yes	Yes	Yes
Multicast static group traffic filtering (for snooping scenarios)		Yes	Yes	Yes	Yes

IGMP snooping overview

When a device processes a multicast packet, by default, the device broadcasts the packets to all ports except the incoming port of a VLAN. Packets are flooded by hardware without going to the CPU. This behavior causes some clients to receive unwanted traffic.

IGMP snooping provides multicast containment by forwarding traffic to only the ports that have IGMP receivers for a specific multicast group (destination address). A device maintains the IGMP group membership information by processing the IGMP reports and leave messages, so traffic can be forwarded to ports receiving IGMP reports.

An IPv4 multicast address is a destination address in the range of 224.0.0.0 to 239.255.255.255. Addresses of 224.0.0.X are reserved. Because packets destined for these addresses may require VLAN flooding, devices do not do snooping in the reserved range. Data packets destined to addresses in reserved range are flooded to the entire VLAN by hardware, and mirrored to the CPU. Multicast data packets destined for the non-reserved range of addresses are snooped. A client must send IGMP reports in order to receive traffic. If an application outside the reserved range requires VLAN flooding, the user must configure a static group that applies to the entire VLAN. In addition, a static group with the drop option can discard multicast data packets to a specified group in hardware, including addresses in the reserved range.

An IGMP device is responsible for broadcasting general queries periodically, and sending group queries when it receives a leave message, to confirm that none of the clients on the port still want specific traffic before removing the traffic from the port. IGMPv2 lets clients specify what group (destination address) will receive the traffic but not to specify the source of the traffic. IGMPv3 is for source-specific multicast traffic, adding the capability for clients to INCLUDE or EXCLUDE specific traffic sources. An IGMPv3 device port state could be INCLUDE or EXCLUDE, and there are different types of group records for client reports.

The interfaces respond to general or group queries by sending a membership report that contains one or more of the following records associated with a specific group:

- Current-state record that indicates from which sources the interface wants to receive and not receive traffic. This record contains the source address of interfaces and whether or not traffic will be included (IS_IN) or not excluded (IS_EX) from this source.
- Filter-mode-change record. If the interface state changes from IS_IN to IS_EX, a TO_EX record is included in the membership report. Likewise, if the interface state changes from IS_EX to IS_IN, a TO_IN record appears in the membership report.
- An IGMPv2 leave report is equivalent to a TO_IN (empty) record in IGMPv3. This record means that no traffic from this group will be received regardless of the source.
- An IGMPv2 group report is equivalent to an IS_EX (empty) record in IGMPv3. This record means that all traffic from this group will be received regardless of source.
- Source-list-change record. If the interface wants to add or remove traffic sources from its membership report, the report can contain an ALLOW record, which includes a list of new sources from which the interface wishes to receive traffic. It can also contain a BLOCK record, which lists the current traffic sources from which the interface wants to stop receiving traffic.

IGMP protocols provide a method for clients and a device to exchange messages, and let the device build a database indicating which port wants what traffic. The protocols do not specify forwarding methods. They require IGMP snooping or multicast protocols such as PIM or DVMRP to handle packet forwarding. PIM and DVMRP can route multicast packets within and outside a VLAN, while IGMP snooping can switch packets only within a VLAN. Currently, FWS and FCX devices do not support multicast routing.

If a VLAN is not IGMP snooping-enabled, it floods multicast data and control packets to the entire VLAN in hardware. When snooping is enabled, IGMP packets are trapped to the CPU. Data packets are mirrored to the CPU in addition to being VLAN flooded. The CPU then installs hardware resources, so that subsequent data packets can be switched to desired ports in hardware without going to the CPU. If there is no client report or port to queriers for a data stream, the hardware resource drops it. The hardware can either match the group address only (* G), or both the source and group (S G) of the data stream. If any IGMPv3 is configured in any port of a VLAN, this VLAN uses (S G) match; otherwise, it uses (* G). This is 32-bit IP address matching, not 23-bit multicast MAC address 01-00-5e-xx-xx-xx matching.

Brocade FWS and FCX devices have 16K of hardware resources allocated to MAC learning, IGMP, and MLD snooping. If a data packet does not match any of these resources, it might be sent to the CPU, which increases the CPU burden. This can happen if the device runs out of hardware resource, or is unable to install resources for a specific matching address due to hashing collision. The hardware hashes addresses into 16K entries, with some addresses hashed into the same entry. If the collision number in an entry is more than the hardware chain length, the resource cannot be installed. The chain length can be configured using the **hash-chain-length** command.

```
Brocade(config)# hash-chain-length 8
```

Syntax: [no] hash-chain-length <num>

The `<num>` value can be 4, 8, 16, or 32. Any other value is truncated to the closest lower ceiling. For example, a value of 15 is changed to 8. The default hash chain length is 4. A chain length of more than 4 may affect line rate switching.

NOTE

For this command to take effect, you must save the configuration and reload the switch.

The hardware resource limit applies only to the VLANs where IGMP snooping is enabled. Multicast streams are switched in hardware without using any pre-installed resources in a VLAN where snooping is not enabled.

FastIron devices support up to 8K of IGMP groups, which are produced by client membership reports.

Configuration notes for IGMP snooping

- Servers (traffic sources) are not required to send IGMP memberships.
- The default IGMP version is V2.
- Hardware resource is installed only when there is data traffic. If a VLAN is configured for IGMPv3, the hardware matches (S G), otherwise it matches (* G).
- A user can configure the maximum numbers of groups and hardware switched data streams.
- The device supports static groups that apply to the entire VLAN, or to just a few ports. The device acts as a proxy to send IGMP reports for the static groups when receiving queries. The static group has a drop option to discard multicast data packets in hardware.
- A user can configure static router ports to force all multicast traffic to these specific ports.
- The devices support fast leave for IGMPv2. Fast leave stops traffic immediately when the port receives a leave message.
- The devices support tracking and fast leave for IGMPv3, tracking all IGMPv3 clients. If the only client on a port leaves, traffic is stopped immediately.
- An IGMP device can be configured as a querier (active) or non-querier (passive). Queriers send queries. Non-queriers listen for queries and forward them to the entire VLAN.
- Every VLAN can be independently configured to be a querier or a non-querier.
- If a VLAN has a connection to a PIM- or DVMRP-enabled port on another router, this VLAN must be configured as a non-querier (passive). When multiple snooping devices connect together and there is no connection to PIM or DVMRP ports, one device must be configured as a querier (active). If multiple devices are configured as active (queriers), only one will keep sending queries after exchanging queries.
- An IGMP device can be configured to rate-limit the forwarding IGMPv2 membership reports to queriers.
- The querier must configure an IP address to send out queries.
- When VSRP or VSRP-aware is configured on a VLAN, the VLAN will support IGMP snooping version 2 only. IGMP version 3 will not be supported on the VLAN.
- When OSPF/PIM/VRRP is configured on a VLAN on the FCX, the VLAN will support IGMP snooping version 1 and version 2. IGMP snooping version 3 will not be supported on the VLAN.

The implementation allows snooping on some VLANs or all VLANs. Each VLAN can independently enable or disable IGMP, or configure V2 or V3. In general, global configuration commands **ip multicast** apply to every VLAN except those that have local multicast configurations (which supersede the global configuration). IGMP also allows independent configuration of individual ports in a VLAN for either IGMPv2 or IGMPv3. Configuring a specific version on a port or a VLAN only applies to the device's sent queries. The device always processes client reports of any version regardless of the configured version.

IGMP snooping requires hardware resources. If resources are inadequate, the data stream without a resource is mirrored to CPU in addition to being VLAN flooded, which can cause high CPU usage. Brocade recommends that you avoid global enabling of snooping unless necessary.

When any port in a VLAN is configured for IGMPv3, the VLAN matches both source and group (S G) in hardware switching. If no ports are configured for IGMPv3, the VLAN matches group only (* G). Matching (S G) requires more hardware resources than matching (* G) when there are multiple servers sharing the same group. For example, two data streams from different sources to the same group require two (S G) entries in IGMPv3, but only one (* G) in IGMPv2. To conserve resources, IGMPv3 must be used only in source-specific applications. When VLANs are independently configured for versions, some VLANs can match (* G) while others match (S G).

IGMP snooping requires clients to send membership reports in order to receive data traffic. If a client application does not send reports, you must configure static groups to force traffic to client ports. A static group can apply to only some ports or to the entire VLAN.

Querier and non-querier configuration

An IGMP snooping-enabled device can be configured as a querier (active) or non-querier (passive). An IGMP querier sends queries; a non-querier listens for IGMP queries and forwards them to the entire VLAN. Also, VLANs can be independently configured to be queriers or non-queriers. If a VLAN has a connection to a PIM- or DVMRP-enabled port on another router, the VLAN must be configured as a non-querier. When multiple IGMP snooping devices are connected together, and there is no connection to a PIM- or DVMRP-enabled port, one of the devices must be configured as a querier. If multiple devices are configured as queriers, after these devices exchange queries, then all except the winner stop sending queries. The device with the lowest address becomes the querier. Although the system will work when multiple devices are configured as queriers, Brocade recommends that only one device (preferably the one with the traffic source) is configured as a querier.

The non-queriers always forward multicast data traffic and IGMP messages to router ports which receive IGMP queries or PIM or DVMRP hellos. Brocade recommends that you configure the device with the data traffic source (server) as a querier. If a server is attached to a non-querier, the non-querier always forwards traffic to the querier regardless of whether there are any clients on the querier.

NOTE

In a topology of one or more connecting devices, at least one device must be running PIM or DVMRP configured as active. Otherwise, none of the devices can send out queries, and traffic cannot be forwarded to clients.

VLAN specific configuration

You can configure IGMP snooping on some VLANs or on all VLANs. Each VLAN can be independently enabled or disabled for IGMP snooping, and can be configured for IGMPv2 or IGMPv3. In general, the **ip multicast** commands apply globally to all VLANs except those configured with VLAN-specific multicast commands. The VLAN-specific multicast commands supersede the global **ip multicast** commands.

IGMPv2 with IGMPv3

IGMP snooping can be configured for IGMPv2 or IGMPv3 on individual ports on a VLAN. An interface or router sends the queries and reports that include its IGMP version specified on it. The version configuration only applies to sending queries. The snooping device recognizes and processes IGMPv2 and IGMPv3 packets regardless of the version configuration.

To avoid version deadlock, an interface retains its version configuration even when it receives a report with a lower version.

PIM SM traffic snooping overview

When multiple PIM sparse routers connect through a snooping-enabled device, the device always forwards multicast traffic to these routers. For example, PIM sparse routers R1, R2, and R3 connect through a device. Assume R2 needs traffic, and R1 sends it to the device, which forwards it to both R2 and R3, even though R3 does not need it. A PIM snooping-enabled device listens to join and prune messages exchanged by PIM sparse routers, and stops traffic to the router that sends prune messages. This allows the device to forward the data stream to R2 only.

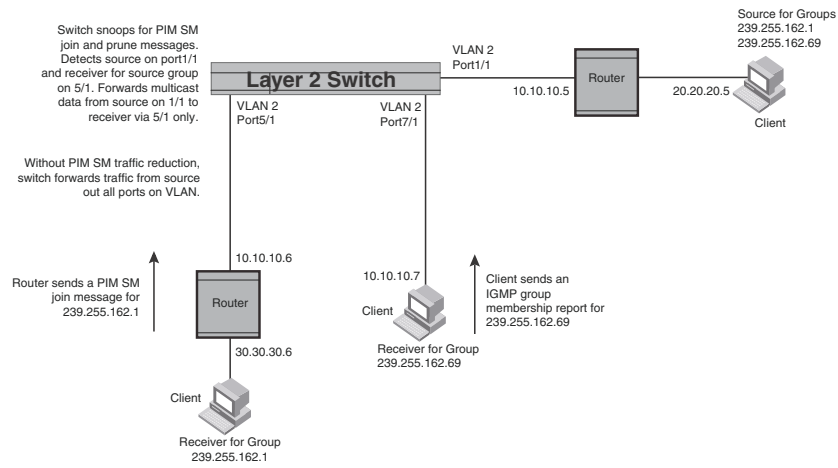

PIM SM traffic snooping requires IP multicast traffic reduction to be enabled on the device. IP multicast traffic reduction configures the device to listen for IGMP messages. PIM SM traffic snooping provides a finer level of multicast traffic control by configuring the device to listen specifically for PIM SM join and prune messages sent from one PIM SM router to another through the device.

NOTE

This feature applies only to PIM SM version 2 (PIM V2).

Application example of PIM SM traffic snooping

[Figure 171](#) shows an example application of the PIM SM traffic snooping feature. In this example, a device is connected through an IP router to a PIM SM group source that is sending traffic for two PIM SM groups. The device also is connected to a receiver for each of the groups.

FIGURE 171 PIM SM traffic reduction in an enterprise network**NOTE**

IP address 239.192.0.0/14 must be used for IPv4 Organization Local Scope.

When PIM SM traffic snooping is enabled, the device starts listening for PIM SM join and prune messages and IGMP group membership reports. Until the device receives a PIM SM join message or an IGMP group membership report, the device forwards IP multicast traffic out all ports. Once the device receives a join message or group membership report for a group, the device forwards subsequent traffic for that group only on the ports from which the join messages or IGMP reports were received.

In this example, the router connected to the receiver for group 239.255.162.1 sends a join message toward the group source. Because PIM SM traffic snooping is enabled on the device, the device examines the join message to learn the group ID, then makes a forwarding entry for the group ID and the port connected to the receiver router. The next time the device receives traffic for 239.255.162.1 from the group source, the device forwards the traffic only on port 5/1, because that is the only port connected to a receiver for the group.

Notice that the receiver for group 239.255.162.69 is directly connected to the device. As a result, the device does not see a join message on behalf of the client. However, since IP multicast traffic reduction also is enabled, the device uses the IGMP group membership report from the client to select the port for forwarding traffic to group 239.255.162.69 receivers.

The IP multicast traffic reduction feature and the PIM SM traffic snooping feature together build a list of groups and forwarding ports for the VLAN. The list includes PIM SM groups learned through join messages as well as MAC addresses learned through IGMP group membership reports. In this case, even though the device never sees a join message for the receiver for group 239.255.162.69, the device nonetheless learns about the receiver and forwards group traffic to the receiver.

The device stops forwarding IP multicast traffic on a port for a group if the port receives a prune message for the group.

Notice that the ports connected to the source and the receivers are all in the same port-based VLAN on the device. This is required for the PIM SM snooping feature. The devices on the edge of the Global Ethernet cloud are configured for IP multicast traffic reduction and PIM SM traffic snooping. Although this application uses multiple devices, the feature has the same requirements and works the same way as it does on a single device.

IGMP snooping configuration

To configure IGMP snooping on FWS, FCX, and ICX devices, you need to perform the following global and VLAN-specific tasks.

Global IGMP snooping tasks

Perform the following global tasks:

- [“Configuring the hardware and software resource limits”](#) on page 1498
- [“Enabling or disabling transmission and receipt of IGMP packets on a port”](#) on page 1498
- [“Configuring the global IGMP mode”](#) on page 1498 (Must be enabled for IGMP snooping)
- [“Modifying the age interval”](#) on page 1499
- [“Modifying the query interval \(active IGMP snooping mode only\)”](#) on page 1499
- [“Configuring the global IGMP version”](#) on page 1499
- [“Configuring report control”](#) on page 1499 (rate limiting)
- [“Modifying the wait time before stopping traffic when receiving a leave message”](#) on page 1500
- [“Modifying the multicast cache age time”](#) on page 1500
- [“Enabling or disabling error and warning messages”](#) on page 1500
- [“Enabling or disabling PIM sparse snooping”](#) on page 1500

VLAN-specific IGMP snooping tasks

Perform the following VLAN-specific tasks:

- [“Configuring the IGMP mode for a VLAN”](#) on page 1501 (active or passive)
- [“Disabling IGMP snooping for the VLAN”](#) on page 1501
- [“Disabling PIM sparse mode snooping for the VLAN”](#) on page 1501
- [“Configuring the IGMP version for the VLAN”](#) on page 1502
- [“Configuring the IGMP version for individual ports”](#) on page 1502
- [“Configuring static groups to the entire VLAN or to specific ports”](#) on page 1502
- [“Configuring static router ports”](#) on page 1503
- [“Turning off static group proxy”](#) on page 1503
- [“Enabling IGMPv3 membership tracking and fast leave for the VLAN”](#) on page 1503
- [“Configuring fast leave for IGMPv2”](#) on page 1504
- [“Enabling fast convergence”](#) on page 1504

Configuring the hardware and software resource limits

The system supports up to 8K of hardware-switched multicast streams. The configurable range is from 256 through 8192 with a default of 512. However, for ICX 6430 devices, the range is from 256 through 1024, and the default is 256. Enter the **system-max igmp-snoop-mcache** command to define the maximum number of IGMP snooping cache entries.

```
Brocade(config)# system-max igmp-snoop-mcache 8000
```

Syntax: [no] **system-max igmp-snoop-mcache** <num>

The system supports up to 32K of groups. The configurable range is from 256 through 32768 and the default is 8192. However, for ICX 6430, the range is from 256 through 1024, and the default is 256, while for ICX 6450, the default is 4096. The configured number is the upper limit of an expandable database. Client memberships exceeding the group limits are not processed. Enter the **system-max igmp-max-group-addr** command to define the maximum number of IGMP group addresses.

```
Brocade(config)# system-max igmp-max-group-addr 1600
```

Syntax: [no] **system-max igmp-max-group-addr** <num>

Enabling or disabling transmission and receipt of IGMP packets on a port

When a VLAN is snooping-enabled, all IGMP packets are trapped to CPU without hardware VLAN flooding. The CPU can block IGMP packets to and from a multicast-disabled port, and does not add it to the output interfaces of hardware resources. This prevents the disabled port from receiving multicast traffic. However, if static groups to the entire VLAN are defined, the traffic from these groups is VLAN flooded, including to disabled ports. Traffic from disabled ports cannot be blocked in hardware, and is switched in the same way as traffic from enabled ports.

This command has no effect on a VLAN that is not snooping-enabled because all multicast traffic is VLAN flooded.

```
Brocade(config)# interface ethernet 0/1/3
Brocade(config-if-e1000-0/1/3)# ip-multicast-disable
```

Syntax: [no] **ip-multicast-disable**

Configuring the global IGMP mode

You can configure active or passive IGMP modes on an FWS, FCX, or ICX device. The default mode is passive. If you specify an IGMP mode for a VLAN, it overrides the global setting.

- **Active** - When active IGMP mode is enabled, an FWS or FCX device actively sends out IGMP queries to identify multicast groups on the network, and makes entries in the IGMP table based on the group membership reports it receives.
- **Passive** - When passive IGMP mode is enabled, it forwards reports to the router ports which receive queries. IGMP snooping in the passive mode does not send queries. However, it forwards queries to the entire VLAN.

To globally set the IGMP mode to active, enter the **ip multicast active** command.

```
Brocade(config)# ip multicast active
```

Syntax: [no] **ip multicast** [active | passive]

If you do not enter either *active* or *passive*, the passive mode is assumed.

Modifying the age interval

When the device receives a group membership report, it makes an entry for that group in the IGMP group table. The age interval specifies how long the entry can remain in the table before the device receives another group membership report. When multiple devices connect together, all devices must be configured for the same age interval, which must be at least twice the length of the query interval, so that missing one report won't stop traffic. Non-querier age intervals must be the same as the age interval of the querier.

To modify the age interval, enter the **ip multicast age-interval** command.

```
Brocade(config)# ip multicast age-interval 280
```

Syntax: [no] **ip multicast age-interval** <interval>

The <interval> parameter specifies the aging time. You can specify a value from 20 through 7200 seconds. The default is 140 seconds.

Modifying the query interval (active IGMP snooping mode only)

For a device with an active IGMP mode, you can modify the query interval to specify how often the device sends general queries. When multiple queriers connect together, they must all be configured with the same query interval.

To modify the query interval, enter the **ip multicast query-interval** command.

```
Brocade(config)# ip multicast query-interval 120
```

Syntax: [no] **ip multicast query-interval** <interval>

The <interval> parameter specifies the time between queries. You can specify a value from 10 through 3600 seconds. The default is 125 seconds.

Configuring the global IGMP version

You can globally specify IGMPv2 or IGMPv3 for the device. The default is IGMPv2. For example, the **ip multicast version 3** command causes the device to use IGMPv3.

```
Brocade(config)# ip multicast version 3
```

Syntax: [no] **ip multicast version 2 | 3**

You can also optionally specify the IGMP version for individual VLANs, or individual ports within VLANs. When no IGMP version is specified for a VLAN, the global IGMP version is used. When an IGMP version is specified for individual ports within a VLAN, the ports use that version, instead of the VLAN version or the global version. The default is IGMPv2.

Configuring report control

A device in passive mode forwards reports and leave messages from clients to the upstream router ports that are receiving queries.

You can configure report control to rate-limit report forwarding within the same group to no more than once every 10 seconds. This rate-limiting does not apply to the first report answering a group-specific query.

NOTE

This feature applies to IGMPv2 only. The leave messages are not rate limited.

IGMPv2 membership reports of the same group from different clients are considered to be the same and are rate-limited.

Use the **ip multicast report-control** command to alleviate report storms from many clients answering the upstream router query.

```
Brocade(config)# ip multicast report-control
```

Syntax: [no] **ip multicast report-control**

The original command, **ip igmp-report-control**, has been renamed to **ip multicast report-control**. The original command is still accepted; however, it is renamed when you issue a **show configuration** command.

Modifying the wait time before stopping traffic when receiving a leave message

You can define the wait time before stopping traffic to a port when a leave message is received. The device sends group-specific queries once per second to ask if any client in the same port still needs this group. The value range is from 1 through 5, and the default is 2. Due to internal timer granularity, the actual wait time is between n and $(n+1)$ seconds (n is the configured value).

```
Brocade(config)# ip multicast leave-wait-time 1
```

Syntax: [no] **ip multicast leave-wait-time** <num>

Modifying the multicast cache age time

You can set the time for an mcache to age out when it does not receive traffic. The traffic is hardware switched. One minute before aging out an mcache, the device mirrors a packet of this mcache to CPU to reset the age. If no data traffic arrives within one minute, this mcache is deleted. A lower value quickly removes resources consumed by idle streams, but it mirrors packets to CPU often. A higher value is recommended only data streams are continually arriving. The range is from 60 through 3600 seconds, and the default is 60 seconds.

```
Brocade(config)# ip multicast mcache-age 180
```

Syntax: [no] **ip multicast mcache-age** <num>

Enabling or disabling error and warning messages

The device prints error or warning messages when it runs out of software resources or when it receives packets with the wrong checksum or groups. These messages are rate-limited. You can turn off these messages by entering the **ip multicast verbose-off** command.

```
Brocade(config)# ip multicast verbose-off
```

Syntax: [no] **ip multicast verbose-off**

Enabling or disabling PIM sparse snooping

PIM snooping must be used only in topologies where multiple PIM sparse routers connect through a device. PIM snooping does not work on a PIM dense mode router which does not send join messages, and traffic to PIM dense ports is stopped. A PIM snooping-enabled device displays a warning if it receives PIM dense join or prune messages. Configure PIM sparse snooping by entering the **ip pimsm-snooping** command.

```
Brocade(config)# ip pimsm-snooping
```

Syntax: [no] ip pimsm-snooping

NOTE

The device must be in passive mode before it can be configured for PIM snooping.

Configuring the IGMP mode for a VLAN

You can configure a VLAN to use the active or passive IGMP mode. The default mode is passive. The setting specified for the VLAN overrides the global setting:

- **Active** - An active IGMP mode device actively sends out IGMP queries to identify multicast groups on the network, and makes entries in the IGMP table based on the group membership reports received.
- **Passive** - A passive IGMP mode device forwards reports to the router ports which receive queries. IGMP snooping in the passive mode forwards queries to the entire VLAN, but it does not send queries.

To set the IGMP mode for VLAN 20 to active, enter the following commands.

```
Brocade(config)# vlan 20
Brocade(config-vlan-20)# multicast active
```

Syntax: [no] multicast active | passive

Disabling IGMP snooping for the VLAN

When IGMP snooping is enabled globally, you can still disable it for a specific VLAN. For example, the following commands cause IGMP snooping to be disabled for VLAN 20. This setting overrides the global setting.

```
Brocade(config)# vlan 20
Brocade(config-vlan-20)# multicast disable-igmp-snoop
```

Syntax: [no] multicast disable-igmp-snoop

Enabling PIM sparse mode snooping for the VLAN

You can enable PIM snooping for a specific VLAN. For example, the following commands enable PIM snooping on VLAN 20.

```
Brocade(config)# vlan 20
Brocade(config-vlan-20)# multicast pimsm-snooping
```

Syntax: [no] multicast pimsm-snooping

Disabling PIM sparse mode snooping for the VLAN

When PIM snooping is enabled globally, you can still disable it for a specific VLAN. For example, the following commands disable PIM snooping for VLAN 20. This setting overrides the global setting.

```
Brocade(config)# vlan 20
Brocade(config-vlan-20)# multicast disable-pimsm-snoop
```

Syntax: [no] multicast disable-pimsm-snoop

Configuring the IGMP version for the VLAN

You can specify the IGMP version for a VLAN. For example, the following commands configure VLAN 20 to use IGMPv3.

```
Brocade(config)# vlan 20
Brocade(config-vlan-20)# multicast version 3
```

Syntax: [no] multicast version 2 | 3

If no IGMP version is specified, then the globally-configured IGMP version is used. If an IGMP version is specified for individual ports, those ports use that version, instead of the VLAN version.

Configuring the IGMP version for individual ports

You can specify the IGMP version for individual ports in a VLAN. For example, the following commands configure ports 0/1/4, 0/1/5, 0/1/6 and 0/2/1 to use IGMPv3. The other ports either use the IGMP version specified with the multicast version command, or the globally-configured IGMP version.

```
Brocade(config)# vlan 20
Brocade(config-vlan-20)# multicast port-version 3 ethernet 0/2/1 ethernet 0/1/4
to 0/1/6
```

Syntax: [no] multicast port-version 2 | 3 <port-numbers>

Configuring static groups to the entire VLAN or to specific ports

A snooping-enabled VLAN cannot forward multicast traffic to ports that do not receive IGMP membership reports. If clients cannot send reports, you can configure a static group which applies to the entire VLAN or only to specific ports. The static group allows packets to be forwarded to the static group ports even though they have no client membership reports. The static group to the entire VLAN is used in VLAN flooding, which consumes less hardware resource than the static group to ports.

The static group drop option discards data traffic to a group in hardware. The group can be any multicast group including groups in the reserved range of 224.0.0.X. The drop option does not apply to IGMP packets, which are always trapped to CPU when snooping is enabled. The drop option applies to the entire VLAN, and cannot be configured for a port list. When the drop option is not specified, the group must exist outside the reserved range.

```
Brocade(config)# vlan 20
Brocade(config-vlan-20)# multicast static-group 224.1.1.1 count 2 ethernet 0/1/3
ethernet 0/1/5 to 0/1/7
Brocade(config-vlan-20)# multicast static-group 239.1.1.1 count 3 drop
Brocade(config-vlan-20)# multicast static-group 239.1.1.1
```

Syntax: [no] multicast static-group <ipv4-address> [count <num>] [<port-numbers> | drop]

The <ipv4-address> parameter is the address of the multicast group.

The count is optional, which allows a contiguous range of groups. Omitting the count <num> is equivalent to the count being 1.

If no <port-numbers> are entered, the static groups apply to the entire VLAN.

Configuring static router ports

FastIron Stackable devices forward all multicast control and data packets to router ports which receive queries. Although router ports are learned, you can force multicast traffic to specified ports even though these ports never receive queries. To configure static router ports, enter the following commands.

```
Brocade(config)# vlan 70
Brocade(config-vlan-70)# multicast router-port ethernet 0/1/4 to 0/1/5 ethernet
0/1/8
```

Syntax: [no] multicast router-port ethernet <port> [ethernet <port> | to <port>]

Specify the <port> variable in the format <stack-unit/slotnum/portnum>.

To specify a list of ports, enter each port as **ethernet <port>** followed by a space. For example, **ethernet 0/1/4 ethernet 0/1/5 ethernet 0/1/8**

To specify a range of ports, enter the first port in the range as **ethernet <port>** followed by the last port in the range. For example, **ethernet 0/1/1 to 0/1/8**.

You can combine lists and ranges in the same command. For example: **enable ethernet 0/1/1 to 0/1/8 ethernet 0/1/24 ethernet 0/2/2 ethernet 0/2/4**.

Turning off static group proxy

If a device has been configured for static groups, it acts as a proxy and sends membership reports for the static groups when it receives general or group-specific queries. When a static group configuration is removed, it is deleted from active group table immediately. However, leave messages are not sent to the querier, and the querier must age the group out. Proxy activity can be turned off. The default is on. To turn proxy activity off for VLAN 20, enter the following commands.

```
Brocade(config)# vlan 20
Brocade(config-vlan-20)# multicast proxy-off
```

Syntax: [no] multicast proxy-off

Enabling IGMPv3 membership tracking and fast leave for the VLAN

IGMPv3 gives clients membership tracking and fast leave capability. In IGMPv2, only one client on an interface needs to respond to a router's queries. This can leave some clients invisible to the router, making it impossible to track the membership of all clients in a group. When a client leaves the group, the device sends group-specific queries to the interface to see if other clients on that interface need the data stream of the client who is leaving. If no client responds, the device waits a few seconds before it stops the traffic. You can configure the wait time using the **ip multicast leave-wait-time** command.

IGMPv3 requires every client to respond to queries, allowing the device to track all clients. When tracking is enabled, and an IGMPv3 client sends a leave message and there is no other client, the device immediately stops forwarding traffic to the interface. This feature requires the entire VLAN be configured for IGMPv3 with no IGMPv2 clients. If a client does not send a report during the specified group membership time (the default is 140 seconds), that client is removed from the tracking list.

Every group on a physical port keeps its own tracking record. However, it can only track group membership; it cannot track by (source, group). For example, Client A and Client B belong to group1 but each receives traffic streams from different sources. Client A receives a stream from (source_1, group1) and Client B receives a stream from (source_2, group1). The device still waits for the configured leave-wait-time before it stops the traffic because these two clients are in the same group. If the clients are in different groups, then the waiting period is not applied and traffic is stopped immediately.

To enable the tracking and fast leave feature for VLAN 20, enter the following commands.

```
Brocade(config)# vlan 20
Brocade(config-vlan-20)# multicast tracking
```

Syntax: [no] multicast tracking

The membership tracking and fast leave features are supported for IGMPv3 only. If any port or any client is not configured for IGMPv3, then the multicast tracking command is ignored.

Configuring fast leave for IGMPv2

When a device receives an IGMPv2 leave message, it sends out multiple group-specific queries. If no other client replies within the waiting period, the device stops forwarding traffic. When fast-leave-v2 is configured, and when the device receives a leave message, it immediately stops forwarding to that port. The device does not send group specific-queries. You must ensure that no snooping-enabled ports have multiple clients. When two devices connect together, the querier must not be configured for fast-leave-v2, because the port might have multiple clients through the non-querier. The number of queries, and the waiting period (in seconds) can be configured using the **ip multicast leave-wait-time** command. The default is 2 seconds.

To configure fast leave for IGMPv2, enter the following commands.

```
Brocade(config)# vlan 20
Brocade(config-vlan-20)# multicast fast-leave-v2
```

Syntax: [no] multicast fast-leave-v2

Enabling fast convergence

In addition to sending periodic general queries, an active device sends general queries when it detects a new port. However, because the device does not recognize the other device's port up event, multicast traffic might still require up to the query-interval time to resume after a topology change. Fast convergence allows the device to listen to topology change events in Layer 2 protocols such as spanning tree, and then send general queries to shorten the convergence time.

If the Layer 2 protocol cannot detect a topology change, fast convergence may not work in some cases. For example, if the direct connection between two devices switches from one interface to another, the rapid spanning tree protocol (802.1w) considers this optimization, rather than a topology change. In this example, other devices will not receive topology change notifications, and will be unable to send queries to speed up the convergence. Fast convergence works well with the regular spanning tree protocol in this case.

To enable fast-convergence, enter the following commands.

```
Brocade(config)# vlan 70
Brocade(config-vlan-70)# multicast fast-convergence
```

Syntax: multicast fast-convergence

Displaying IGMP snooping information

This section describes the **show** commands for IGMP snooping.

Displaying IGMP errors

To display information about possible IGMP errors, enter the **show ip multicast error** command.

```
Brocade# show ip multicast error
snoop SW processed pkt: 173, up-time 160 sec
```

Syntax: **show ip multicast error**

The following table describes the output from the **show ip multicast error** command.

Field	Description
SW processed pkt	The number of multicast packets processed by IGMP snooping.
up-time	The time since the IGMP snooping is enabled.

Displaying IGMP group information

To display information about IGMP groups, enter the **show ip multicast group** command.

```
Brocade# show ip multicast group
p-:physical, ST:static, QR:querier, EX:exclude, IN:include, Y:yes, N:no
VL70 : 3 groups, 4 group-port, tracking_enabled
      group      p-port  ST    QR    life mode    source
1      224.1.1.2    0/1/33 no    yes   120 EX      0
2      224.1.1.1    0/1/33 no    yes   120 EX      0
3      226.1.1.1    0/1/35 yes   yes   100 EX      0
4      226.1.1.1    0/1/33 yes   yes   100 EX      0
```

In this example, an IGMPv2 group is in EXCLUDE mode with a source of 0. The group only excludes traffic from the 0 (zero) source list, which actually means that all traffic sources are included.

To display detailed IGMP group information, enter the **show ip multicast group detail** command.

```
Brocade# show ip multicast group 226.1.1.1 detail
Display group 226.1.1.1 in all interfaces in details.
p-:physical, ST:static, QR:querier, EX:exclude, IN:include, Y:yes, N:no
VL70 : 1 groups, 2 group-port, tracking_enabled
      group      p-port  ST    QR    life mode    source
1      226.1.1.1    0/1/35 yes   yes   120 EX      0
  group: 226.1.1.1, EX, permit 0 (source, life):
    life=120, deny 0:
      group      p-port  ST    QR    life mode    source
2      226.1.1.1    0/1/33 yes   yes   120 EX      0
  group: 226.1.1.1, EX, permit 0 (source, life):
    life=120, deny 0:
```

If the tracking and fast leave features are enabled, you can display the list of clients that belong to a particular group by entering the following command.

```
Brocade# show ip multicast group 224.1.1.1 tracking
Display group 224.1.1.1 in all interfaces with tracking enabled.
p-:physical, ST:static, QR:querier, EX:exclude, IN:include, Y:yes, N:no
VL70 : 1 groups, 1 group-port, tracking_enabled
      group      p-port  ST    QR    life mode    source
*** Note: has 1 static groups to the entire vlan, not displayed here
1      224.1.1.1      0/1/33  no    yes    100  EX      0
      receive reports from 1 clients: (age)
      (2.2.100.2 60)
```

Syntax: `show ip multicast group [<group-address> [detail] [tracking]]`

If you want a report for a specific multicast group, enter that group's address for `<group-address>`.

Enter detail to display the source list of a specific VLAN.

Enter tracking for information on interfaces that have tracking enabled.

The following table describes the information displayed by the **show ip multicast group** command.

Field	Description
group	The address of the group (destination address in this case, 224.1.1.1)
p-port	The physical port on which the group membership was received.
ST	Yes indicates that the IGMP group was configured as a static group; No means the address was learned from reports.
QR	Yes means the port is a querier port; No means it is not. A port becomes a non-querier port when it receives a query from a source with a lower source IP address than the device.
life	The number of seconds the group can remain in EXCLUDE mode. An EXCLUDE mode changes to INCLUDE mode if it does not receive an "IS_EX" or "TO_EX" message during a certain period of time. The default is 140 seconds. There is no life displayed in INCLUDE mode.
mode	Indicates current mode of the interface: INCLUDE or EXCLUDE. If the interface is in INCLUDE mode, it admits traffic only from the source list. If an interface is in EXCLUDE mode, it denies traffic from the source list and accepts the rest.
source	Identifies the source list that will be included or excluded on the interface. For example, if an IGMPv2 group is in EXCLUDE mode with a source of 0, the group excludes traffic from the 0 (zero) source list, which actually means that all traffic sources are included.

Displaying IGMP snooping mcache information

The IGMP snooping mcache contains multicast forwarding information for VLANs. To display information in the multicast forwarding mcache, enter the **show ip multicast mcache** command.

```
Brocade# show ip multicast mcache
Example: (S G) cnt=: cnt: SW proc. count
        OIF: 0/1/22 TR(0/1/32,0/1/33), TR is trunk, 0/1/32 primary, 0/1/33 output
vlan 1, 1 caches. use 1 VIDX
1      (1.2.10.102 225.1.1.1) cnt=46
        OIF: 0/1/4
        age=0m up-time=45m vidx=4130 (ref-cnt=1)
vlan 70, 1 caches. use 1 VIDX
1      (* 226.1.2.3) cnt=69
        OIF: 0/1/14
        age=0m up-time=59m vidx=4129 (ref-cnt=1)
```

Syntax: show ip multicast mcache

The following table describes the output of the **show ip multicast mcache** command.

Field	Description
(source group)	Source and group addresses of this data stream. (* group) means match group only; (source group) means match both.
cnt	The number of packets processed in software. Packets are switched in hardware, which increases this number slowly.
OIF	The output interfaces. If entire vlan is displayed, this indicates that static groups apply to the entire VLAN.
age	The mcache age. The mcache will be reset to 0 if traffic continues to arrive, otherwise the mcache will be aged out when it reaches the time defined by the ip multicast mcache-age command.
uptime	The up time of this mcache in minutes.
vidx	Vidx specifies output port list index. Range is from 4096 to 8191
ref-cnt	The vidx is shared among mcaches having the same output interfaces. Ref-cnt indicates the number of mcaches using this vidx.

Displaying PIM sparse snooping information

PIM sparse mode snooping allows a device to listen for join or prune messages exchanged between PIM routers, which helps reduce unwanted traffic. To display PIM snooping information, enter the **show ip multicast pimsm-snooping** command.

```
Brocade# show ip multicast pimsm-snooping
vlan 1, has 1 caches.
1      (1.2.10.102 225.1.1.1) has 0 pim join ports out of 1 OIF
vlan 70, has 1 caches.
1      (* 226.1.2.3) has 2 pim join ports out of 2 OIF
        0/1/14 (age=60), 0/1/13 (age=60),
        0/1/14 has 1 src: 1.1.30.99(60)
        0/1/13 has 1 src: 1.1.30.99(60)
```

This output shows the number of OIF due to PIM out of the total OIF. The join or prune messages are source-specific. In this case, if the mcache is in (* G), the display function will also print the traffic source information.

Displaying software resource usage for VLANs

To display information about the software resources used, enter the **show ip multicast resource** command.

```
Brocade# show ip multicast resource
          alloc  in-use  avail get-fail    limit  get-mem  size init
igmp group          0      0      0         0    6000        0   16  256
igmp phy port        0      0      0         0 200000        0   22 1024
igmp exist phy port  256   107   149         0 1589248    107   29  256
igmp G/GS query      0      0      0         0  29696         0   12  128
igmp v3 source        0      0      0         0 500000         0   10 2000
igmp v3 tracking      0      0      0         0 118784         0   10  512
igmp glb sorted list  0      0      0         0 500000         0    8 2000
igmp generic link    128    12   116         0  29696        12    8  128
igmp generic multi-l 256     0   256         0  59392        12   16  256
igmp VIF             64    12    52         0  14848        12  170   64
snoop mcache entry    0      0      0         0    512         0  289  128
snoop group hash OIF  0      0      0         0 200000        0   12 2000
snoop group hash      0      0      0         0  59392         0   16  256
snoop router port     0      0      0         0  14848         0   15   64
snoop OIF            0      0      0         0  59392         0   23  256
IGMP snoop hitless s  0      0      0         0  29696         0   17  128
dynamic link hash     0      0      0         0  14848         0   20   64
snoop MCT OIF list    0      0      0         0 200000        0    8 2000
total pool memory 23424 bytes
has total 0 forwarding hash
VIDX sharing ha no no 997      0      0      0      0      0
Available vidx: 4003. IGMP/MLD use 0
```

Syntax: show ip multicast resource

The following table describes the output from the **show ip multicast resource** command.

Field	Description
alloc	The allocated number of units.
in-use	The number of units which are currently being used.
avail	The number of available units.
get-fail	This displays the number of resource failures. NOTE: It is important to pay attention to this field.
limit	The upper limit of this expandable field. The limit of multicast group is configured by the system-max igmp-max-group-addr command. The limit of snoop mcache entry is configured by the system-max multicast-snoop-mcache command.
get-mem	The number of memory allocation. This number should continue to increase.
size	The size of a unit (in bytes).
init	The initial allocated amount of memory. More memory can be allocated if resources run out.
Available vidx	The output interface (OIF) port mask used by mcache. The entire device has a maximum of 4096 vidx. Different mcaches with the same OIF share the same vidx. If vidx is not available, the stream cannot be hardware-switched.

Displaying status of IGMP snooping traffic

To display status information for IGMP snooping traffic, enter the **show ip multicast traffic** command.

```
Brocade# show ip multicast traffic
IGMP snooping: Total Recv: 22, Xmit: 26
Q: query, Qry: general Q, G-Qry: group Q, GSQry: group-source Q, Mbr: member
Recv      QryV2      QryV3      G-Qry      GSQry      MbrV2      MbrV3      Leave
VL1        0         0         0         0         4         0         0
VL70       18         0         0         0         0         0         0
Recv      IsIN      IsEX      ToIN      ToEX      ALLOW      BLOCK      Pkt-Err
VL1        0         4         0         0         0         0         0
VL70       0         0         0         0         0         0         0

Send      QryV2      QryV3      G-Qry      GSQry      MbrV2      MbrV3
VL1        0         0         8         0         0         0
VL70       0         0         0         0         0         18
VL70  pimsm-snooping, Hello: 12, Join/Prune: 9
```

Syntax: show ip multicast traffic

The following table describes the information displayed by the **show ip multicast traffic** command.

Field	Description
Q	Query
Qry	General Query
QryV2	Number of general IGMPv2 queries received or sent.
QryV3	Number of general IGMPv3 queries received or sent.
G-Qry	Number of group-specific queries received or sent.
GSQry	Number of group source-specific queries received or sent.
Mbr	The membership report.
MbrV2	The IGMPv2 membership report.
MbrV3	The IGMPv3 membership report.
IsIN	Number of source addresses that were included in the traffic.
IsEX	Number of source addresses that were excluded in the traffic.
ToIN	Number of times the interface mode changed from EXCLUDE to INCLUDE.
ToEX	Number of times the interface mode changed from INCLUDE to EXCLUDE.
ALLO	Number of times that additional source addresses were allowed on the interface.
BLK	Number of times that sources were removed from an interface.
Pkt-Err	Number of packets having errors, such as checksum.
Pimsm-snooping hello, join, prune	Number of PIM sparse hello, join, and prune packets

Displaying IGMP snooping information by VLAN

You can display IGMP snooping information for all VLANs or for a specific VLAN. For example, to display IGMP snooping information for VLAN 70, enter the **show ip multicast vlan number** command.

```
Brocade# show ip multicast vlan 70
version=2, query-t=30, group-aging-t=140, max-resp-t=3, other-qr-present-t=63
VL70: dft V2, vlan cfg passive, , pimsm (vlan cfg), track, 0 grp, 1 (*G) cache,
rtr ports,
  router ports: 0/1/13(140) 1.1.70.3, 0/1/20(180) 1.1.70.2, 0/1/14(180)
0/1/13 has 0 groups, non-QR (passive), default V2
0/1/14 has 0 groups, non-QR (passive), default V2
0/1/20 has 0 groups, non-QR (passive), default V2
```

Syntax: **show ip multicast vlan** [**<vlan-id>**]

If you do not specify a **<vlan-id>**, information for all VLANs is displayed.

The following table describes the information displayed by the **show ip multicast vlan** command.

Field	Description
version	The IGMP version number
query-t	How often a querier sends a general query on the interface.
group-aging-t	The number of seconds membership groups can be members of this group before aging out.
rtr-port	The router ports which are the ports receiving queries. The display <code>router ports: 0/1/13(140) 1.1.70.3</code> means port 0/1/13 has a querier with 1.1.70.3 address, and a remaining life of 140 seconds.
max-resp-t	The maximum number of seconds a client waits before it replies to the query.
non-QR	Indicates that the port is a non-querier.
QR	Indicates that the port is a querier.
dft	The IGMP version for the specified VLAN. In this example, VL70: dft V2 indicates that the default IGMP version V2 is set for VLAN 70.

Displaying querier information

You can use the **show ip multicast vlan** command to display the querier information for a VLAN. This command displays the VLAN interface status and if there is any other querier present with the lowest IP address. The following list provides the combinations of querier possibilities:

- Active interface with no other querier present
- Passive interface with no other querier present
- Active interface with other querier present
- Passive interface with other querier present

Active interface with no other querier present

The following example shows the output in which the VLAN interface is active and no other querier is present with the lowest IP address.

```
Brocade# show ip multicast vlan 10
Version=2, Intervals: Query=125, Group Age=260, Max Resp=10, Other Qr=260
VL10: dft V2, vlan cfg active, 0 grp, 0 (*G) cache, no rtr port,

    1/1/16 has    0 groups,
This interface is Querier
default V2

    1/1/24 has    0 groups,
This interface is Querier
default V2

    2/1/16 has    0 groups,
This interface is Querier
default V2

    2/1/24 has    0 groups,
This interface is Querier
default V2

    3/1/1  has    0 groups,
This interface is Querier
default V2

    3/1/4  has    0 groups,
This interface is Querier
default V2
```

Syntax: `show ip multicast vlan <vlan-id>`

If you do not specify a <vlan-id>, information for all VLANs is displayed.

Passive interface with no other querier present

The following example shows the output in which the VLAN interface is passive and no other querier is present with the lowest IP address.

```
Brocade# show ip multicast vlan 10
Version=2, Intervals: Query=125, Group Age=260, Max Resp=10, Other Qr=260
VL10: dft V2, vlan cfg passive, 0 grp, 0 (*G) cache, no rtr port,

    1/1/16 has    0 groups,
This interface is non-Querier (passive)
default V2

    1/1/24 has    0 groups,
This interface is non-Querier (passive)
default V2

    2/1/16 has    0 groups,
This interface is non-Querier (passive)
default V2

    2/1/24 has    0 groups,
```

Displaying IGMP snooping information

```
This interface is non-Querier (passive)
default V2
```

```
3/1/1 has 0 groups,
This interface is non-Querier (passive)
default V2
```

```
3/1/4 has 0 groups,
This interface is non-Querier (passive)
default V2
```

Active interface with other querier present

The following example shows the output in which the VLAN interface is active and another querier is present with the lowest IP address.

```
Brocade# show ip multicast vlan 10
Version=2, Intervals: Query=125, Group Age=260, Max Resp=10, Other Qr=260
```

```
VL10: dft V2, vlan cfg active, 7 grp, 6 (*G) cache, rtr ports,

Clear IGMP snooping commands

The clear IGMP snooping commands must be used only in troubleshooting conditions, or to recover from errors.

Clearing IGMP counters on VLANs

To clear IGMP snooping on error and traffic counters for all VLANs, enter the **clear ip multicast counters** command.

```
Brocade# clear ip multicast counters
```

Syntax: clear ip multicast counters

Clearing IGMP mcache

To clear the mcache on all VLANs, enter the **clear ip multicast mcache** command.

```
Brocade# clear ip multicast mcache
```

Syntax: clear ip multicast mcache

Clearing mcache on a specific VLAN

To clear the mcache on a specific VLAN, enter the **clear ip multicast vlan <vlan-id> mcache** command.

```
Brocade# clear ip multicast vlan 10 mcache
```

Syntax: clear ip multicast vlan <vlan-id> mcache

The <vlan-id> parameter specifies the specific VLAN in which to clear the mcache.

Clearing traffic on a specific VLAN

To clear the traffic counters on a specific VLAN, enter the **clear ip multicast vlan <vlan-id> traffic** command.

```
Brocade# clear ip multicast vlan 10 traffic
```

Syntax: clear ip multicast vlan <vlan-id> traffic

The <vlan-id> parameter specifies the specific VLAN in which to clear the traffic counters.

IP Multicast Protocols

Table 253 lists the individual Brocade FastIron switches and the IP multicast features they support. These features are supported in the full Layer 3 software image only.

TABLE 253 Supported IP multicast features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
Internet Group Management Protocol (IGMP) V1, V2, and V3 (for multicast routing scenarios)	Yes	No	Yes	Yes	No
IGMPv3 fast leave (for routing)	Yes	No	Yes	Yes	No
Protocol Independent Multicast Dense mode (PIM-DM) V1 (draft-ietf-pim-dm-05) and V2 (draft-ietf-pim-v2-dm-03)	Yes	No	Yes	Yes	No
Protocol Independent Multicast Sparse mode (PIM-SM) V2 (RFC 2362)	Yes	No	Yes	Yes	No
PIM passive	Yes	No	Yes	Yes	No
Distance Vector Multicast Routing Protocol (DVMRP) V2 (RFC 1075)	Yes	No	No	No	No
IP tunneling for multicast traffic	Yes	No	No	No	No
Anycast RP	Yes	No	No	No	No
Multicast Source Discovery Protocol (MSDP)	Yes	No	No	No	No
IGMP proxy	Yes	No	Yes	Yes	No
Passive multicast route insertion (PMRI)	Yes	No	Yes	Yes	No
Disable CPU processing for select multicast groups	Yes	No	No	No	No
Static multicast routes	Yes	No	No	No	No
Multicast trace route	Yes	No	No	No	No
IP multicast and IGMP snooping on the same device	Yes	No	Yes	Yes	No
ACLs to control multicast features	Yes	No	Yes	Yes	No
Static multicast groups	Yes	No	Yes	Yes	No

This chapter describes how to configure Brocade Layer 3 switches for Protocol Independent Multicast (PIM) and Distance Vector Multicast Routing Protocol (DVMRP).

NOTE

Each multicast protocol uses IGMP. IGMP is automatically enabled on an interface when you configure PIM or DVMRP and is disabled on the interface if you disable PIM or DVMRP.

NOTE

This chapter applies only to IP multicast routing. To configure Layer 2 multicast features, refer to [Chapter 34, “IP Multicast Traffic Reduction on Brocade FastIron X Series switches”](#) and [Chapter 35, “IP Multicast Traffic Reduction for FastIron WS and Brocade FCX and ICX Switches”](#).

IP multicast overview

Multicast protocols allow a group or channel to be accessed over different networks by multiple stations (clients) for the receipt and transmit of multicast data.

Distribution of stock quotes, video transmissions such as news services and remote classrooms, and video conferencing are all examples of applications that use multicast routing.

IPv4 multicast group addresses

In IPv4 Multicast, host groups are identified by Class D addresses, i.e., those with “1110” as their higher-order four bits. In Internet standard “dotted decimal” notation, these group addresses range from 224.0.0.0 to 239.255.255.255. However, the IANA IPv4 Multicast Address Registry (referencing RFC 3171) stipulates that the range 224.0.0.0 through 224.0.0.255 should not be used for regular multicasting applications.

“The range of addresses between 224.0.0.0 and 224.0.0.255, inclusive, is reserved for the use of routing protocols and other low-level topology discovery or maintenance protocols, such as gateway discovery and group membership reporting. Multicast routers should not forward any multicast datagram with destination addresses in this range, regardless of its TTL.”

Mapping of IPv4 Multicast group addresses to Ethernet MAC addresses

The IANA owns a block of Ethernet MAC addresses for Multicast usage that are in the range 0100.5e00.0000 through 0100.5e7f.ffff. For a given IPv4 Multicast group, there is a simple way of obtaining the appropriate Ethernet Destination MAC address that must be used in Layer 2 encapsulation. This is defined in RFC 1112, as follows:

“An IP host group address is mapped to an Ethernet multicast address by placing the low-order 23-bits of the IP address into the low-order 23 bits of the Ethernet multicast address 01-00-5E-00-00-00 (hex). Because there are 28 significant bits in an IP host group address, more than one host group address may map to the same Ethernet multicast address.”

NOTE

Since there are 5 bits in the IPv4 Group address that are not used in the mapping, there is a possibility for up to 32 IPv4 Multicast Groups to use the same Ethernet Destination MAC address. Taking this into account along with the reserved IPv4 Group address range, it is discouraged for applications to use IPv4 Multicast Group Addresses that may conflict with the reserved addresses at the Layer 2 level. This is because some devices may use just the Ethernet Destination MAC address to take actions on the packet.

Supported Layer 3 multicast routing protocols

Brocade Layer 3 switches support the multicast routing protocol DVMRP and PIM along with the Internet Group Membership Protocol (IGMP).

PIM and DVMRP are broadcast and pruning multicast protocol that deliver IP multicast datagrams. The protocol employs reverse path lookup check and pruning to allow source-specific multicast delivery trees to reach all group members. DVMRP and PIM build a different multicast tree for each source and destination host groups.

NOTE

DVMRP and PIM can concurrently operate on different ports of a Brocade Layer 3 switch.

Suppression of unregistered multicast packets

By default, unregistered multicast packets are always forwarded in hardware but not copied to the CPU. However on FSX platforms, if Layer 2 multicast (IGMP or MLD) or Layer 3 multicast (**router pim**) is enabled, then unregistered multicast packets are forwarded in hardware and also copied to the CPU.

Multicast terms

The following are commonly used terms in discussing multicast-capable routers. These terms are used throughout this chapter:

- **Node:** Refers to a router or Layer 3 switch.
- **Root Node:** The node that initiates the tree building process. It is also the router that sends the multicast packets down the multicast delivery tree.
- **Upstream:** Represents the direction from which a router receives multicast data packets. An upstream router is a node that sends multicast packets.
- **Downstream:** Represents the direction to which a router forwards multicast data packets. A downstream router is a node that receives multicast packets from upstream transmissions.
- **Group Presence:** Means that a multicast group has been learned from one of the directly connected interfaces. Members of the multicast group are present on the router.
- **Intermediate nodes:** Routers that are in the path between source routers and leaf routers.
- **Leaf nodes:** Routers that do not have any downstream routers.
- **Multicast Tree:** A unique tree is built for each source group (S,G) pair. A multicast tree is comprised of a root node and one or more nodes that are leaf or intermediate nodes.

Global IP multicast parameters

The following configurable parameters apply to PIM-DM, PIM-SM and DVMRP

- **Maximum number of PIM groups** – You can change the maximum number of groups of each type for which the software will allocate memory. By default, FastIron X Series Layer 3 switches support up to 1024 PIM groups. Brocade FCX Series Layer 3 switches support up to 4000 PIM groups.

- Maximum number of DVMRP groups – You can change the maximum number of groups for which the software will allocate memory. By default, FastIron X Series Layer 3 Switches support up to 1024 DVMRP groups.
- Internet Group Membership Protocol (IGMP) V1 and V2 parameters – You can change the query interval, group membership time, and maximum response time.
- Hardware forwarding of fragmented IP multicast packets – You can enable the Layer 3 switch to forward all fragments of fragmented IP multicast packets in hardware.

Changing dynamic memory allocation for IP multicast groups

Layer 3 switches support up to 1024 PIM groups and 1024 DVMRP groups by default. Memory for the groups is allocated dynamically as needed. For each protocol, previous releases support a maximum of 255 groups and 255 IGMP memberships.

NOTE

The number of interface groups you can configure for DVMRP and PIM is unlimited; therefore, the **system-max dvmrp-max-int-group** and the **system-max pim-max-int-group** commands that define their maximum table sizes have been removed.

The software allocates memory globally for each group, and also allocates memory separately for each interface IGMP membership in a multicast group. An interface becomes a member of a multicast group when the interface receives an IGMP group membership report. For example, if the Layer 3 switch learns about one multicast group, global memory for one group is used. In addition, if three interfaces on the device receive IGMP group membership reports for the group, interface memory for three IGMP memberships also is used.

Since the same group can use multiple allocations of memory (one for the group itself and one for each interface membership in the group), you can increase the maximum number of IGMP memberships, up to 8192.

NOTE

The total for IGMP memberships applies to the device, not to individual interfaces. You can have up to 8192 IGMP memberships on all the individual interfaces, not up to 8192 IGMP memberships on each interface.

Defining the maximum number of DVMRP cache entries

The DVMRP cache system parameter defines the maximum number of repeated DVMRP traffic being sent from the same source address and being received by the same destination address. To define this maximum, enter the **system-max dvmrp-mcache <num>** command.

```
Brocade(config)#system-max dvmrp-mcache 500
```

Syntax: **system-max dvmrp-mcache <num>**

The <num> parameter specifies the maximum number of multicast cache entries for DVMRP. Enter a number from 128 – 4096. The default is 512.

Defining the maximum number of PIM cache entries

The PIM cache system parameter defines the maximum number of repeated PIM traffic being sent from the same source address and being received by the same destination address. To define this maximum, enter the **system-max pim-mcache <num>** command.

```
Brocade(config)#system-max pim-mcache 999
```

Syntax: **system-max pim-mcache <num>**

The <num> parameter specifies the maximum number of multicast cache entries for PIM. Enter a number from 256 – 4096. The default is 1024.

Changing IGMP V1 and V2 parameters

IGMP allows Brocade routers to limit the multicast of IGMP packets to only those ports on the router that are identified as IP Multicast members. This section applies to Brocade devices that support IGMP versions 1 and 2.

The router actively sends out host queries to identify IP Multicast groups on the network, inserts the group information in an IGMP packet, and forwards the packet to IP Multicast neighbors.

The following IGMP V1 and V2 parameters apply to PIM and DVMRP:

- IGMP query interval – Specifies how often the Layer 3 switch queries an interface for group membership.
- IGMP group membership time – Specifies how many seconds an IP Multicast group can remain on a Layer 3 switch interface in the absence of a group report.
- IGMP maximum response time – Specifies how many seconds the Layer 3 switch will wait for an IGMP response from an interface before concluding that the group member on that interface is down and then removing the interface from the group.

To change these parameters, you must first enable IP multicast routing by entering the **ip multicast-routing** command at the global CLI level.

```
Brocade(config)#ip multicast-routing
```

Syntax: **[no] ip multicast-routing**

NOTE

You must enter the **ip multicast-routing** command before changing the global IP Multicast parameters. Otherwise, the changes do not take effect and the software uses the default values.

Modifying IGMP (V1 and V2) query interval period

The IGMP query interval period defines how often a router will query an interface for group membership.

To modify the default value for the IGMP (V1 and V2) query interval, enter the **ip igmp query-interval <num>** command.

```
Brocade(config)#ip igmp query-interval 120
```

Syntax: **ip igmp query-interval <num>**

The <num> variable specifies the IGMP query interval in number of seconds. Enter a value from 10 through 3600. The default value is 125.

Modifying IGMP (V1 and V2) membership time

The group membership time defines how long a group will remain active on an interface in the absence of a group report.

To define an IGMP (V1 and V2) membership time of 240 seconds, enter the **ip igmp group-membership-time <num>** command.

```
Brocade(config)#ip igmp group-membership-time 240
```

Syntax: **ip igmp group-membership-time <num>**

The <num> variable specifies the IGMP group membership time in number of seconds. Enter a value from 20 through 7200 seconds. The value you enter must be a little more than two times the query interval (2*query-interval +10). The default value is 260.

Modifying IGMP (V1 and V2) maximum response time

Maximum response time defines how long the Layer 3 switch will wait for an IGMP (V1 and V2) response from an interface before concluding that the group member on that interface is down, and then removing the interface from the group.

To change the IGMP (V1 and V2) maximum response time, enter the **ip igmp max-response-time <num>** command at the global CONFIG level of the CLI.

```
Brocade(config)#ip igmp max-response-time 8
```

Syntax: **[no] ip igmp max-response-time <num>**

The <num> parameter specifies the IGMP maximum response time in number of seconds. Enter a value from 1 through 10. The default is 10.

NOTE

Adding an interface to a multicast group

You can manually add an interface to a multicast group. This is useful in the following cases:

- Hosts attached to the interface are unable to add themselves as members of the group using IGMP.
- There are no members for the group attached to the interface.

When you manually add an interface to a multicast group, the Brocade device forwards multicast packets for the group but does not itself accept packets for the group.

You can manually add a multicast group to individual ports only. If the port is a member of a virtual routing interface, you must add the ports to the group individually.

To manually add a port to a multicast group, enter a command such as the following at the configuration level for the port.

```
Brocade(config-if-1/1)#ip igmp static-group 224.2.2.2
```

This command adds port 1/1 to multicast group 224.2.2.2.

To add a port that is a member of a virtual routing interface to a multicast group, enter a command such as the following at the configuration level for the virtual routing interface.

```
Brocade(config-vif-1)#ip igmp static-group 224.2.2.2 ethernet 5/2
```

This command adds port 5/2 in virtual routing interface 1 to multicast group 224.2.2.2.

Syntax: `[no] ip igmp static-group <ip-addr> [[count <number>] | drop | [ethernet <portnum>]]`

The `<ip-addr>` parameter specifies the group number.

The **count** `<number>` parameter specifies the number of contiguous groups per vlan. The `<number>` variable must be from 1 through 512.

The **drop** parameter specifies the number of dropped multicast packets. The **drop** option is available only for static groups on a vlan.

NOTE

On FSX devices, the **drop** option is not available for a multicast group.

The **ethernet** `<portnum>` parameter specifies the port number. Use this parameter if the port is a member of a virtual routing interface, and you are entering this command at the configuration level for the virtual routing interface.

Manually added groups are included in the group information displayed by the following commands:

- `show ip igmp group`
- `show ip pim group`

PIM Dense

NOTE

This section describes the “dense” mode of PIM, described in RFC 1075. Refer to [“PIM Sparse”](#) on page 1531 for information about PIM Sparse.

PIM was introduced to simplify some of the complexity of the routing protocol at the cost of additional overhead tied with a greater replication of forwarded multicast packets. PIM builds source-routed multicast delivery trees and employs reverse path check when forwarding multicast packets.

There are two modes in which PIM operates: Dense and Sparse. The Dense Mode is suitable for densely populated multicast groups, primarily in the LAN environment. The Sparse Mode is suitable for sparsely populated multicast groups with the focus on WAN.

PIM uses the IP routing table instead of maintaining its own, thereby being routing protocol independent.

Initiating PIM multicasts on a network

Once PIM is enabled on each router, a network user can begin a video conference multicast from the server on R1 as shown in [Figure 172](#). When a multicast packet is received on a PIM-capable router interface, the interface checks its IP routing table to determine whether the interface that received the message provides the shortest path back to the source. If the interface does provide the shortest path back to the source, the multicast packet is then forwarded to all neighboring PIM routers. Otherwise, the multicast packet is discarded and a prune message is sent back upstream.

In [Figure 172](#), the root node (R1) is forwarding multicast packets for group 229.225.0.1, which it receives from the server, to its downstream nodes, R2, R3, and R4. Router R4 is an intermediate router with R5 and R6 as its downstream routers. Because R5 and R6 have no downstream interfaces, they are leaf nodes. The receivers in this example are those workstations that are resident on routers R2, R3, and R6.

Pruning a multicast tree

As multicast packets reach these leaf routers, the routers check their IGMP databases for the group. If the group is not in a router IGMP database, the router discards the packet and sends a prune message to the upstream router. The router that discarded the packet also maintains the prune state for the source, group (S,G) pair. The branch is then pruned (removed) from the multicast tree. No further multicast packets for that specific (S,G) pair will be received from that upstream router until the prune state expires. You can configure the PIM Prune Timer (the length of time that a prune state is considered valid).

For example, in [Figure 172](#) the sender with address 207.95.5.1 is sending multicast packets to the group 229.225.0.1. If a PIM switch receives any groups other than that group, the switch discards the group and sends a prune message to the upstream PIM switch.

In [Figure 173](#), switch S5 is a leaf node with no group members in its IGMP database. Therefore, the switch must be pruned from the multicast tree. S5 sends a prune message upstream to its neighbor switch S4 to remove itself from the multicast delivery tree and install a prune state, as seen in [Figure 173](#). Switch S5 will not receive any further multicast traffic until the prune age interval expires.

When a node on the multicast delivery tree has all of its downstream branches (downstream interfaces) in the prune state, a prune message is sent upstream. In the case of S4, if both S5 and S6 are in a prune state at the same time, S4 becomes a leaf node with no downstream interfaces and sends a prune message to S1. With S4 in a prune state, the resulting multicast delivery tree would consist only of leaf nodes S2 and S3.

FIGURE 172 Transmission of multicast packets from the source to host group members

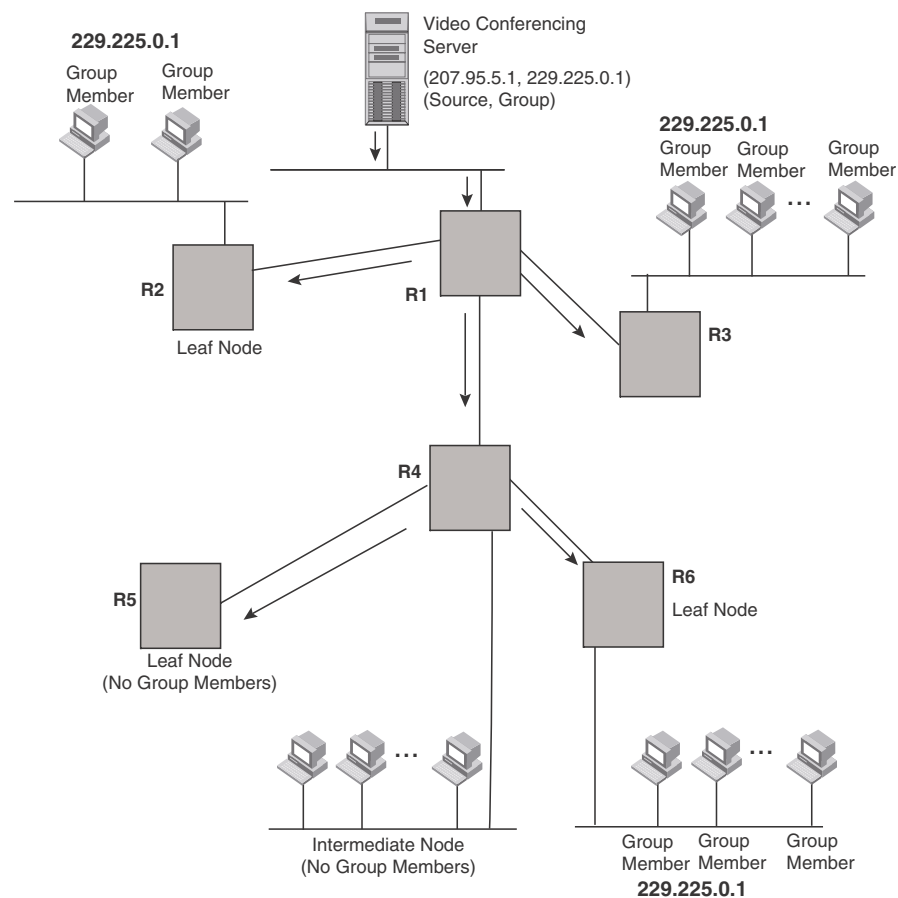

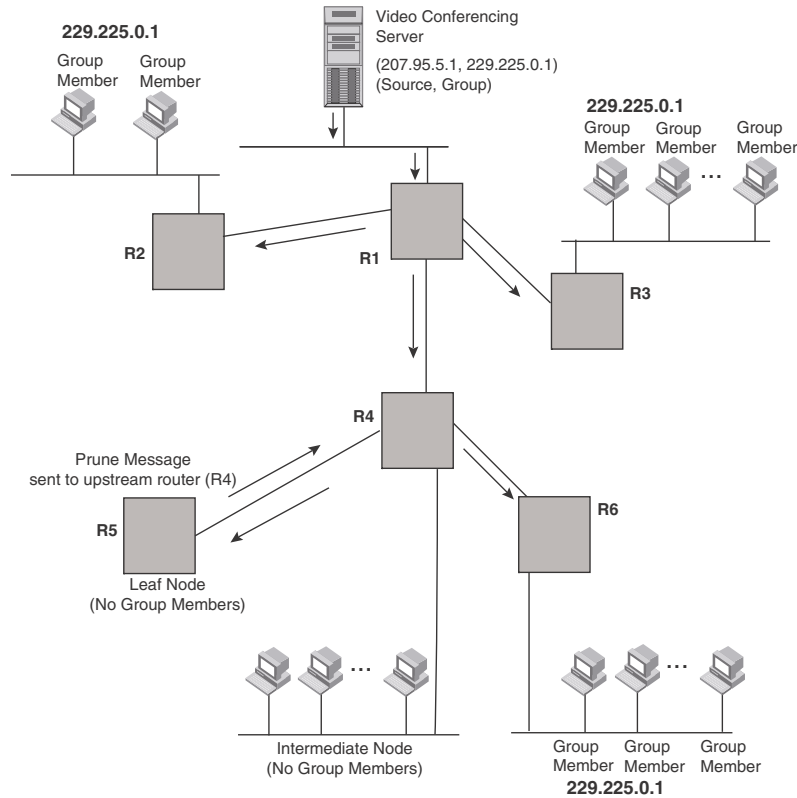

FIGURE 173 Pruning leaf nodes from a multicast tree

Grafts to a multicast Tree

A PIM switch restores pruned branches to a multicast tree by sending graft messages towards the upstream switch. Graft messages start at the leaf node and travel up the tree, first sending the message to its neighbor upstream switch.

In the example above, if a new 229.255.0.1 group member joins on switch S6, which was previously pruned, a graft is sent upstream to S4. Since the forwarding state for this entry is in a prune state, S4 sends a graft to S1. Once S4 has joined the tree, S4 and S6 once again receive multicast packets.

Prune and graft messages are continuously used to maintain the multicast delivery tree. No configuration is required on your part.

PIM DM versions

Brocade devices support PIM DM V1 and V2. The default is V2. You can specify the version on an individual interface basis.

The primary difference between PIM DM V1 and V2 is the methods the protocols use for messaging:

- PIM DM V1 – uses the Internet Group Management Protocol (IGMP) to send messages
- PIM DM V2 – sends messages to the multicast address 224.0.0.13 (ALL-PIM-ROUTERS) with protocol number 103

The CLI commands for configuring and managing PIM DM are the same for V1 and V2. The only difference is the command you use to enable the protocol on an interface.

NOTE

Version 2 is the default PIM DM version. The only difference between version 1 and version 2 is the way the protocol sends messages. The change is not apparent in most configurations. You can use version 2 instead of version 1 with no impact to your network. However, if you want to continue to use PIM DM V1 on an interface, you must change the version, then save the configuration.

NOTE

The note above does not mean you can run different PIM versions on devices that are connected to each other. The devices must run the same version of PIM. If you want to connect a Layer 3 switch running PIM to a device that is running PIM V1, you must change the version on the Layer 3 switch to V1 (or change the version on the device to V2, if supported).

PIM DM configuration

NOTE

This section describes how to configure the “dense” mode of PIM, described in RFC 1075. Refer to [“PIM Sparse configuration”](#) on page 1533 for information about configuring PIM Sparse.

Enabling PIM on the router and an interface

By default, PIM is disabled. To enable PIM, perform the following:

- Enable the feature globally.
- Configure the IP interfaces that will use PIM.
- Enable PIM locally on the ports that have the IP interfaces you configured for PIM.

Suppose you want to initiate the use of desktop video for fellow users on a sprawling campus network. All destination workstations have the appropriate hardware and software but the Brocade routers that connect the various buildings need to be configured to support PIM multicasts from the designated video conference server as shown in [Figure 172](#) on page 1523.

PIM is enabled on each of the Brocade routers shown in [Figure 172](#), on which multicasts are expected. You can enable PIM on each router independently or remotely from one of the routers with a Telnet connection. Follow the same steps for each router. A reset of the router is required when PIM is first enabled. Thereafter, all changes are dynamic.

Globally enabling and disabling PIM

To globally enable PIM, enter the following command.

```
Brocade(config)#router pim
```

Syntax: **[no] router pim**

The behavior of the **[no] router pim** command is as follows:

- Entering **router pim** command to enable PIM does not require a software reload.
- Entering a **no router pim** command removes all configuration for PIM multicast on a Layer 3 switch (**router pim** level) only.

Globally Enabling and Disabling PIM without Deleting Multicast Configuration

As stated above entering a **no router pim** command deletes the PIM configuration. If you want to disable PIM without deleting any PIM configuration, enter the following command.

```
Brocade(config)#router pim
Brocade(config-pim-router)#disable-pim
```

Syntax: [no] disable-pim

Use the [no] version of the command to re-enable PIM.

Enabling a PIM version

Using the CLI

To enable PIM on an interface, globally enable PIM, then enable PIM on interface 3, enter the following commands.

```
Brocade(config)#router pim
Brocade(config)#int e 3
Brocade(config-if-e1000-3)#ip address 207.95.5.1/24
Brocade(config-if-e1000-3)#ip pim
```

Syntax: [no] ip pim [version 1 | 2]

The **version 1 | 2** parameter specifies the PIM DM version. The default version is 2.

If you have enabled PIM version 1 but need to enable version 2 instead, enter either of the following commands at the configuration level for the interface.

```
Brocade(config-if-1/1)#ip pim version 2
Brocade(config-if-1/1)#no ip pim version 1
```

To disable PIM DM on the interface, enter the following command.

```
Brocade(config-if-1/1)#no ip pim
```

Modifying PIM global parameters

PIM global parameters come with preset values. The defaults work well in most networks, but you can modify the following parameters if you need to:

- Neighbor timeout
- Hello timer
- Prune timer
- Prune wait timer
- Graft retransmit timer
- Inactivity timer

Modifying neighbor timeout

Neighbor timeout is the interval after which a PIM router will consider a neighbor to be absent. Absence of PIM hello messages from a neighboring router indicates that a neighbor is not present.

The default value is 180 seconds.

To apply a PIM neighbor timeout value of 360 seconds to all ports on the router operating with PIM, enter the following.

```
Brocade(config)#router pim
Brocade(config-pim-router)#nbr-timeout 360
```

Syntax: **nbr-timeout** <60-8000>

The default is 180 seconds.

Modifying hello timer

This parameter defines the interval at which periodic hellos are sent out PIM interfaces. Routers use hello messages to inform neighboring routers of their presence. The default rate is 60 seconds.

To apply a PIM hello timer of 120 seconds to all ports on the router operating with PIM, enter the following.

```
Brocade(config)#router pim
Brocade(config-pim-router)#hello-timer 120
```

Syntax: **hello-timer** <10-3600>

The default is 60 seconds.

Modifying prune timer

This parameter defines how long a Brocade PIM router will maintain a prune state for a forwarding entry.

The first received multicast interface is forwarded to all other PIM interfaces on the router. If there is no presence of groups on that interface, the leaf node sends a prune message upstream and stores a prune state. This prune state travels up the tree and installs a prune state.

A prune state is maintained until the prune timer expires or a graft message is received for the forwarding entry. The default value is 180 seconds.

To set the PIM prune timer to 90, enter the following.

```
Brocade(config)#router pim
Brocade(config-pim-router)##prune-timer 90
```

Syntax: **prune-timer** <10-3600>

The default is 180 seconds.

Modifying the prune wait timer

The CLI command **prune-wait** allows you to configure the amount of time a PIM router will wait before stopping traffic to neighbor routers that do not want the traffic. The value can be from zero to three seconds. The default is three seconds. A smaller prune wait value reduces flooding of unwanted traffic.

A prune wait value of zero causes the PIM router to stop traffic immediately upon receiving a prune message. If there are two or more neighbors on the physical port, then the **prune-wait** command should not be used because one neighbor may send a prune message while the other sends a join message at the during time or in less than three seconds.

To set the prune wait time to zero, enter the following commands.

```
Brocade(config)#router pim
Brocade(config-pim-router)#prune-wait 0
```

Syntax: `prune-wait <time>`

where <time> can be 0 - 3 seconds. A value of 0 causes the PIM router to stop traffic immediately upon receiving a prune message. The default is 3 seconds.

Viewing the prune wait time

To view the prune wait time, enter the **show ip pim dense** command at any level of the CLI. Refer to [“Displaying basic PIM Dense configuration information”](#) on page 1530.

Modifying graft retransmit timer

The Graft Retransmit Timer defines the interval between the transmission of graft messages.

A graft message is sent by a router to cancel a prune state. When a router receives a graft message, the router responds with a Graft Ack (acknowledge) message. If this Graft Ack message is lost, the router that sent the graft message will resend it.

To change the graft retransmit timer from the default of 180 to 90 seconds, enter the following.

```
Brocade(config)#router pim
Brocade(config-pim-router)#graft-retransmit-timer 10
```

Syntax: `graft-retransmit-timer <2 -10>`

The default is 3 seconds.

Modifying inactivity timer

The router deletes a forwarding entry if the entry is not used to send multicast packets. The PIM inactivity timer defines how long a forwarding entry can remain unused before the router deletes it.

To apply a PIM inactivity timer of 90 seconds to all PIM interfaces, enter the following.

```
Brocade(config)#router pim
Brocade(config-pim-router)#inactivity-timer 90
```

Syntax: `inactivity-timer <10-3600>`

The default is 180 seconds.

Selection of shortest path back to source

By default, when a multicast packet is received on a PIM-capable router interface in a multi-path topology, the interface checks its IP routing table to determine the shortest path back to the source. If the alternate paths have the same cost, the first alternate path in the table is picked as the path back to the source. For example, in the table below, the first four routes have the same cost back to the source. However, 137.80.127.3 will be chosen as the path to the source since it is the first one on the list. The router rejects traffic from any port other than Port V11 on which 137.80.127.3 resides.

Total number of IP routes: 19

	B:BGP	D:Connected	R:RIP	S:Static	O:OSPF	*:Candidate	default		
		Destination		NetMask		Gateway	Port	Cost	Type
9		172.17.41.4		255.255.255.252	*	137.80.127.3	v11	2	O
		172.17.41.4		255.255.255.252		137.80.126.3	v10	2	O
		172.17.41.4		255.255.255.252		137.80.129.1	v13	2	O
		172.17.41.4		255.255.255.252		137.80.128.3	v12	2	O
10		172.17.41.8		255.255.255.252	0.0.0.0		1/2	1	D

Due to the Highest IP RFP feature, the selection of the shortest path back to the source is based on which Reverse Path Forwarding (RPF) neighbor in the IP routing table has the highest IP address, if the cost of the routes are the same. For example, in the table above, Gateway 137.80.129.1 will be chosen as the shortest path to the source because it is the RPF neighbor with the highest IP address.

When choosing the RPF, the router first checks the Multicast Routing Table. If the table is not available, it chooses an RPF from the IP Routing Table. Multicast route is configured using the **ip mroute** command.

The Highest IP RFP feature is enabled by default.

Failover time in a multi-path topology

When a port in a multi-path topology fails, and the failed port is the input port of the downstream router, a new path is re-established within a few seconds, depending on the routing protocol being used.

No configuration is required for this feature.

Modifying the TTL

The time to live (TTL) defines the minimum value required in a packet for it to be forwarded out of the interface.

For example, if the TTL for an interface is set at 10, it means that only those packets with a TTL value of 10 or more will be forwarded. Likewise, if an interface is configured with a TTL Threshold value of 1, all packets received on that interface will be forwarded. Possible TTL values are 1 to 31. The default TTL value is 1.

Configuration notes for modifying the TTL

- If the TTL for an interface is greater than 1, PIM packets received on the interface are always forwarded in software because each packet TTL must be examined. Therefore, Brocade does not recommend modifying the TTL under normal operating conditions.
- Multicast packets with a TTL value of 1 are switched within the same VLAN. These packets cannot be routed between different VLANs.

Configuration syntax for modifying the TTL

To configure a TTL of 24, enter the following.

```
Brocade(config-if-3/24)#ip pim ttl-threshold 24
```

Syntax: `ip pim ttl-threshold <1-31>`

Dropping PIM traffic in hardware

Unwanted PIM Dense or PIM Sparse multicast traffic can be dropped in hardware on Layer 3 switches. This feature does not apply to DVMRP traffic. Refer to [“Passive multicast route insertion”](#) on page 1579.

Displaying basic PIM Dense configuration information

To display PIM Dense configuration information, enter the **show ip pim dense** command at any CLI level.

```
router(config)# show ip pim dense
Global PIM Dense Mode Settings
Hello interval: 60, Neighbor timeout: 180
Graft Retransmit interval: 3, Inactivity interval: 180
Route Expire interval: 0, Route Discard interval: 0
Prune age: 180, Prune wait: 3

Interface v5
PIM Dense: V2
TTL Threshold: 1, Disabled, DR: itself
Local Address: 209.157.23.1
```

Syntax: `show ip pim dense`

[Table 254](#) shows the information displayed by the **show ip pim dense** command.

TABLE 254 Output of the **show ip pim dense** command

Field	Description
Hello interval	How frequently the device sends hello messages out the PIM dense interfaces.
Neighbor timeout	The interval after which a PIM device will consider a neighbor to be absent.
Graft or Retransmit interval	How interval between the transmission of graft messages.
Inactivity interval	How long a forwarding entry can remain unused before the device deletes it.
Route Expiry Interval	How long a route is considered valid in the absence of the next route update
Route Discard Interval	Defines the period of time before a route is deleted.
Join or Prune interval	How long a PIM device will maintain a prune state for a forwarding entry.

TABLE 254 Output of the **show ip pim dense** command

Field	Description
Prune Age	The number of packets the device sends using the path through the RP before switching to using the SPT path.
Prune Wait Interval	The amount of time a PIM device waits before stopping traffic to neighbor devices that do not want the traffic. The value can be from zero to three seconds. The default is three seconds.
Interface	The type of interface and the interface number.
Local Address	Indicates the IP address configured on the port or virtual interface.
TTL Threshold	The minimum value required in a packet for it to be forwarded out of the interface.
DR	The priority of the designated device.

Displaying all multicast cache entries in a pruned state

You can use the **show ip pim prune** command to display all multicast cache entries that are currently in a pruned state and have not yet aged out.

```
router(config)# show ip pim prune
Port    SourceNet    Group          Nbr    PhyPort    Age
                                     sec
v800 172.10.1.10  239.255.255.250 0.0.0.0  1/1/3     140
```

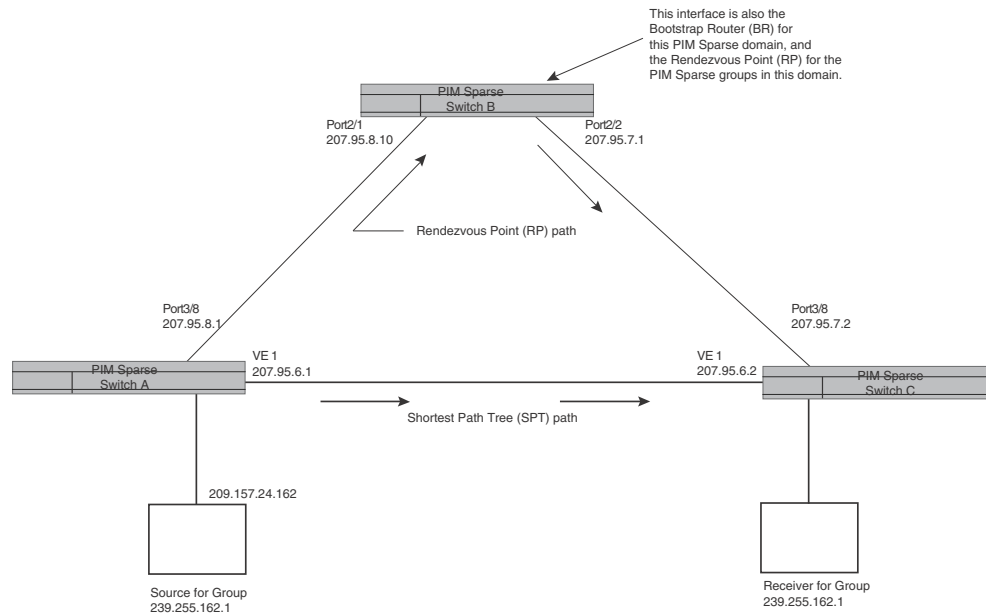

Syntax: **show ip pim prune**

PIM Sparse

Brocade devices support Protocol Independent Multicast (PIM) Sparse version 2. PIM Sparse provides multicasting that is especially suitable for widely distributed multicast environments. The Brocade implementation is based on RFC 2362.

In a PIM Sparse network, a PIM Sparse router that is connected to a host that wants to receive information for a multicast group must explicitly send a join request on behalf of the receiver (host).

PIM Sparse routers are organized into domains. A PIM Sparse domain is a contiguous set of routers that all implement PIM and are configured to operate within a common boundary. [Figure 174](#) shows a simple example of a PIM Sparse domain. This example shows three Layer 3 switches configured as PIM Sparse routers. The configuration is described in detail following the figure.

FIGURE 174 Example of a PIM Sparse domain

PIM Sparse switch types

Switches that are configured with PIM Sparse interfaces also can be configured to fill one or more of the following roles:

- **PMBR** – A PIM switch that has some interfaces within the PIM domain and other interface outside the PIM domain. PMBRs connect the PIM domain to the Internet.

NOTE

You cannot configure a Brocade routing interface as a PMBR interface for PIM Sparse in the current software release.

- **BSR** – The Bootstrap Router (BSR) distributes RP information to the other PIM Sparse switches within the domain. Each PIM Sparse domain has one active BSR. For redundancy, you can configure ports on multiple switches as candidate BSRs. The PIM Sparse protocol uses an election process to select one of the candidate BSRs as the BSR for the domain. The BSR with the highest BSR priority (a user-configurable parameter) is elected. If the priorities result in a tie, then the candidate BSR interface with the highest IP address is elected. In the example in [Figure 174](#), PIM Sparse switch B is the BSR. Port 2/2 is configured as a candidate BSR.
- **RP** – The RP is the meeting point for PIM Sparse sources and receivers. A PIM Sparse domain can have multiple RPs, but each PIM Sparse multicast group address can have only one active RP. PIM Sparse switches learn the addresses of RPs and the groups for which they are responsible from messages that the BSR sends to each of the PIM Sparse switches. In the example in [Figure 174](#), PIM Sparse Switch B is the RP. Port 2/2 is configured as a candidate Rendezvous Point (RP).

To enhance overall network performance, Brocade Layer 3 switches use the RP to forward only the first packet from a group source to the group receivers. After the first packet, the Layer 3 switch calculates the shortest path between the receiver and source (the Shortest Path Tree, or SPT) and uses the SPT for subsequent packets from the source to the receiver. The Layer 3 switch calculates a separate SPT for each source-receiver pair.

NOTE

Brocade recommends that you configure the same ports as candidate BSRs and RPs.

RP paths and SPT paths

[Figure 174](#) shows two paths for packets from the source for group 239.255.162.1 and a receiver for the group. The source is attached to PIM Sparse Switch A and the recipient is attached to PIM Sparse Switch C. PIM Sparse Switch B is the RP for this multicast group. As a result, the default path for packets from the source to the receiver is through the RP. However, the path through the RP sometimes is not the shortest path. In this case, the shortest path between the source and the receiver is over the direct link between Switch A and Switch C, which bypasses the RP (Switch B).

To optimize PIM traffic, the protocol contains a mechanism for calculating the Shortest Path Tree (SPT) between a given source and receiver. PIM Sparse switches can use the SPT as an alternative to using the RP for forwarding traffic from a source to a receiver. By default, Brocade Layer 3 switches forward the first packet they receive from a given source to a given receiver using the RP path, but forward subsequent packets from that source to that receiver through the SPT. In [Figure 174](#), Switch A forwards the first packet from group 239.255.162.1 source to the destination by sending the packet to Switch B, which is the RP. Switch B then sends the packet to Switch C. For the second and all future packets that Switch A receives from the source for the receiver, Switch A forwards them directly to Switch C using the SPT path.

PIM Sparse configuration

To configure a Brocade Layer 3 switch for PIM Sparse, perform the following tasks:

- Configure the following global parameter:
 - Enable the PIM Sparse mode of multicast routing.
- Configure the following interface parameters:
 - Configure an IP address on the interface
 - Enable PIM Sparse.
 - Identify the interface as a PIM Sparse border, if applicable.

NOTE

You cannot configure a Brocade routing interface as a PMBR interface for PIM Sparse in the current software release.

- Configure the following PIM Sparse global parameters:
 - Identify the Layer 3 switch as a candidate PIM Sparse Bootstrap Router (BSR), if applicable.
 - Identify the Layer 3 switch as a candidate PIM Sparse Rendezvous Point (RP), if applicable.
 - Specify the IP address of the RP (if you want to statically select the RP).

NOTE

Brocade recommends that you configure the same Layer 3 switch as both the BSR and the RP.

PIM Sparse limitations in this release

The implementation of PIM Sparse in the current software release has the following limitations:

- PIM Border Routers (PMBRs) are not supported. Thus, you cannot configure a Brocade routing interface as a PMBR interface for PIM Sparse.
- PIM Sparse and regular PIM (dense mode) cannot be used on the same interface.
- You cannot configure or display PIM Sparse information using the Web Management Interface. (You can display some general PIM information, but not specific PIM Sparse information.)

Configuring Global PIM Sparse parameters

To configure the PIM Sparse global parameters, use either of the following methods.

To configure basic global PIM Sparse parameters, enter commands such as the following on each Layer 3 switch within the PIM Sparse domain.

```
Brocade(config)#router pim
```

Syntax: [no] router pim

NOTE

You do not need to globally enable IP multicast routing when configuring PIM Sparse.

The command in this example enables IP multicast routing, and enables the PIM Sparse mode of IP multicast routing. The command does not configure the Layer 3 switch as a candidate PIM Sparse Bootstrap Router (BSR) and candidate Rendezvous Point (RP). You can configure a Brocade Layer 3 switch as a PIM Sparse switch without configuring the it as a candidate BSR and RP. However, if you do configure the Layer 3 switch as one of these, Brocade recommends that you configure it as both. Refer to [“Configuring BSRs”](#) on page 1535.

The behavior of the [no] router pim command is as follows:

- Entering **no router pim** command to disable PIM or DVMRP does not require a software reload.
- Entering a **no router pim** command removes all configuration for PIM multicast on a Layer 3 switch (**router pim** level) only.

Globally enabling and disabling PIM without deleting the multicast configuration

As stated above entering a **no router pim** command deletes the PIM configuration. If you want to disable PIM without deleting any PIM configuration, enter the following command.

```
Brocade(config)#router pim
Brocade(config-pim-router)#disable-pim
```

Syntax: [no] disable-pim

Use the [no] version of the command to re-enable PIM.

Configuring PIM interface parameters

After you enable IP multicast routing and PIM Sparse at the global level, you must enable it on the individual interfaces connected to the PIM Sparse network. To do so, use the following CLI method.

To enable PIM Sparse mode on an interface, enter commands such as the following.

```
Brocade(config)#interface ethernet 2/2
Brocade(config-if-2/2)#ip address 207.95.7.1 255.255.255.0
Brocade(config-if-2/2)#ip pim-sparse
```

Syntax: [no] ip pim-sparse

The commands in this example add an IP interface to port 2/2, then enable PIM Sparse on the interface.

If the interface is on the border of the PIM Sparse domain, you also must enter the following command.

```
Brocade(config-if-2/2)#ip pim border
```

Syntax: [no] ip pim border

NOTE

You cannot configure a Brocade routing interface as a PMBR interface for PIM Sparse in the current software release.

Configuring BSRs

In addition to the global and interface parameters in the sections above, you need to identify an interface on at least one Layer 3 switch as a candidate PIM Sparse boot strap router (BSR) and candidate PIM Sparse Rendezvous Point (RP).

NOTE

It is possible to configure the Layer 3 switch as only a candidate BSR or RP, but Brocade recommends that you configure the same interface on the same Layer 3 switch as both a BSR and an RP.

This section presents how to configure BSRs. Refer to [“Configuring RPs”](#) on page 1536 for instructions on how to configure RPs.

To configure the Layer 3 switch as a candidate BSR and RP, enter commands such as the following.

```
Brocade(config)#router pim
Brocade(config-pim-router)#bsr-candidate ethernet 2/2 30 255
BSR address: 207.95.7.1, hash mask length: 30, priority: 255
```

This command configures the PIM Sparse interface on port 2/2 as a BSR candidate, with a hash mask length of 30 and a priority of 255. The information shown in italics above is displayed by the CLI after you enter the candidate BSR configuration command.

Syntax: [no] bsr-candidate ethernet [<slotnum>]/<portnum> | loopback <num> | ve <num> <hash-mask-length> [<priority>]

The <slotnum> parameter is required on chassis devices.

The <portnum> | loopback <num> | ve <num> parameter specifies the interface. The Layer 3 switch will advertise the specified interface IP address as a candidate BSR:

- Enter **ethernet** [*<slotnum>/*] *<portnum>* for a physical interface (port).
- Enter **ve** *<num>* for a virtual interface.
- Enter **loopback** *<num>* for a loopback interface.

The *<hash-mask-length>* parameter specifies the number of bits in a group address that are significant when calculating the group-to-RP mapping. You can specify a value from 1 – 32.

NOTE

Brocade recommends you specify 30 for IP version 4 (IPv4) networks.

The *<priority>* specifies the BSR priority. You can specify a value from 0 – 255. When the election process for BSR takes place, the candidate BSR with the highest priority becomes the BSR. The default is 0.

Enter the command `show ip pim bsr` to display BSR information. Refer to [“Displaying BSR information”](#) on page 1547.

Configuring RPs

Enter a command such as the following to configure the Layer 3 switch as a candidate rendezvous point (RP).

```
Brocade(config-pim-router)#rp-candidate ethernet 2/2
```

Syntax: `[no] rp-candidate ethernet [<slotnum>/]<portnum> | loopback <num> | ve <num>`

The *<slotnum>* parameter is required on chassis devices.

The *<portnum> | loopback <num> | ve <num>* parameter specifies the interface. The Layer 3 switch will advertise the specified interface IP address as a candidate RP:

- Enter **ethernet** [*<slotnum>/*] *<portnum>* for a physical interface (port).
- Enter **ve** *<num>* for a virtual interface.
- Enter **loopback** *<num>* for a loopback interface.

By default, this command configures the Layer 3 switch as a candidate RP for all group numbers beginning with 224. As a result, the Layer 3 switch is a candidate RP for all valid PIM Sparse group numbers. You can change this by adding or deleting specific address ranges. The following example narrows the group number range for which the Layer 3 switch is a candidate RP by explicitly adding a range.

```
Brocade(config-pim-router)#rp-candidate add 224.126.0.0 16
```

Syntax: `[no] rp-candidate add <group-addr> <mask-bits>`

The *<group-addr> <mask-bits>* specifies the group address and the number of significant bits in the subnet mask. In this example, the Layer 3 switch is a candidate RP for all groups that begin with 224.126. When you add a range, you override the default. The Layer 3 switch then becomes a candidate RP only for the group address ranges you add.

You also can change the group numbers for which the Layer 3 switch is a candidate RP by deleting address ranges. For example, to delete all addresses from 224.126.22.0 – 224.126.22.255, enter the **rp-candidate delete** command.

```
Brocade(config-pim-router)#rp-candidate delete 224.126.22.0 24
```

Syntax: `rp-candidate delete <group-addr> <mask-bits>`

The usage of the `<group-addr> <mask-bits>` parameter is the same as for the **rp-candidate add** command.

If you enter both commands shown in the example above, the net effect is that the Layer 3 switch becomes a candidate RP for groups 224.126.0.0 – 224.126.21.255 and groups 224.126.23.0 – 224.126.255.255.

Updating PIM-Sparse forwarding entries with new RP configuration

If you make changes to your static RP configuration, the entries in the PIM-Sparse multicast forwarding table continue to use the old RP configuration until they are aged out.

The **clear pim rp-map** command allows you to update the entries in the static multicast forwarding table immediately after making RP configuration changes. This command is meant to be used with **rp-address** command.

To update the entries in a PIM sparse static multicast forwarding table with new RP configuration, enter the following command at the privileged EXEC level of the CLI.

```
Brocade#clear pim rp-map
```

Syntax: **clear pim rp-map**

Statically specifying the RP

Brocade recommends that you use the PIM Sparse protocol RP election process so that a backup RP can automatically take over if the active RP router becomes unavailable. However, if you do not want the RP to be selected by the RP election process but instead you want to explicitly identify the RP by its IP address, you can do using the following CLI method.

Even if you explicitly specify the RP, by default the Layer 3 switch uses the set of candidate RPs supplied by the BSR and overrides the specified RP for all group-to-RP mappings.

NOTE

Specify the same IP address as the RP on all PIM Sparse routers within the PIM Sparse domain. Make sure the router is on the backbone or is otherwise well connected to the rest of the network.

To specify the IP address of the RP, enter commands such as the following.

```
Brocade(config)#router pim
Brocade(config-pim-router)#rp-address 207.95.7.1
```

Syntax: **[no] rp-address <ip-addr>**

The `<ip-addr>` parameter specifies the IP address of the RP.

The command in the example above identifies the router interface at IP address 207.95.7.1 as the RP for the PIM Sparse domain. The Layer 3 switch will use the specified RP and ignore group-to-RP mappings received from the BSR.

Changing the Shortest Path Tree (SPT) threshold

In a typical PIM Sparse domain, there may be two or more paths from a DR (designated router) for a multicast source to a PIM group receiver:

- **Path through the RP** – This is the path the Layer 3 switch uses the first time it receives traffic for a PIM group. However, the path through the RP may not be the shortest path from the Layer 3 switch to the receiver.

- **Shortest Path** – Each PIM Sparse router that is a DR for a multicast source calculates a shortest path tree (SPT) to all the PIM Sparse group receivers within the domain, with the Layer 3 switch itself as the root of the tree. The first time a Brocade Layer 3 switch configured as a PIM router receives a packet for a PIM receiver, the Layer 3 switch sends the packet to the RP for the group. The Layer 3 switch also calculates the SPT from itself to the receiver. The next time the Layer 3 switch receives a PIM Sparse packet for the receiver, the Layer 3 switch sends the packet toward the receiver using the shortest route, which may not pass through the RP.

By default, the device switches from the RP to the SPT after receiving the first packet for a given PIM Sparse group. The Layer 3 switch maintains a separate counter for each PIM Sparse source-group pair.

After the Layer 3 switch receives a packet for a given source-group pair, the Layer 3 switch starts a PIM data timer for that source-group pair. If the Layer 3 switch does not receive another packet for the source-group pair before the timer expires, it reverts to using the RP for the next packet received for the source-group pair. In accordance with the PIM Sparse RFC recommendation, the timer is 210 seconds and is not configurable. The counter is reset to zero each time the Layer 3 switch receives a packet for the source-group pair.

You can change the number of packets that the Layer 3 switch sends using the RP before switching to using the SPT. To do so, use the following CLI method.

```
Brocade(config)#router pim
Brocade(config-pim-router)#spt-threshold 1000
```

Syntax: [no] spt-threshold infinity | <num>

The **infinity** | <num> parameter specifies the number of packets. If you specify infinity, the Layer 3 switch sends packets using the RP indefinitely and does not switch over to the SPT. If you enter a specific number of packets, the Layer 3 switch does not switch over to using the SPT until it has sent the number of packets you specify using the RP.

NOTE

Since the hardware is not programmed for RPT, the rate that the client receives multicast traffic depends on the software forwarding capability of the CPU when the Layer 3 Switch sends packets using the RPT.

Changing the PIM join and prune message interval

By default, the Layer 3 switch sends PIM Sparse Join/Prune messages every 60 seconds. These messages inform other PIM Sparse routers about clients who want to become receivers (Join) or stop being receivers (Prune) for PIM Sparse groups.

You can change the Join/Prune message interval using the following CLI method.

NOTE

Use the same Join/Prune message interval on all the PIM Sparse routers in the PIM Sparse domain. If the routers do not all use the same timer interval, the performance of PIM Sparse can be adversely affected.

To change the Join/Prune interval, enter commands such as the following.

```
Brocade(config)#router pim
Brocade(config-pim-router)#message-interval 30
```

Syntax: [no] message-interval <num>

The `<num>` parameter specifies the number of seconds and can range from 1 – 65535. The default is 60.

Dropping PIM traffic in hardware

Unwanted PIM Dense or PIM Sparse multicast traffic can be dropped in hardware on Layer 3 switches. This feature does not apply to DVMRP. Refer to [“Passive multicast route insertion”](#) on page 1579.

ACL based RP assignment

The **rp-address** command allows multiple static RP configurations. For each static RP, an ACL can be given as an option to define the multicast address ranges that the static RP permit or deny to serve.

A static RP by default serves the range of 224.0.0.0/4 if the RP is configured without an ACL name. If an ACL name is given but the ACL is not defined, the static RP is set to inactive mode and it will not cover any multicast group ranges.

The optional static RP ACL can be configured as a standard ACL or as an extended ACL. For an extended ACL, the destination filter will be used to derive the multicast group range and all other filters are ignored. The content of the ACL needs to be defined in the order of prefix length; the longest prefix must be placed at the top of the ACL definition.

If there are overlapping group ranges among the static RPs, the static RP with the longest prefix match is selected. If more than one static RP covers the exact same group range, the highest IP static RP will be used.

Configuration considerations for assigning ACL-based RP

- The RP learned from the BSR has higher precedence over Static RP. For more information, refer to the definition of the `override` parameter in the section [“Using ACLs to limit static RP groups”](#) on page 1588
- There is a limit of 16 static RPs in the systems.

Configuring an ACL based RP assignment

To configure an ACL based RP assignment, enter commands such as the following.

```
Brocade(config)# router pim
Brocade(config-pim-router)# rp-address 130.1.1.1 20
```

Syntax: `[no] rp-address <ip_address> [<acl-num>]`

Use the **ip address** parameter to specify the IP address of the device you want to designate as an RP device.

Use the **acl-num** parameter to specify standard numbered ACL that specifies which multicast groups use this RP.

NOTE

Only standard numbered ACLs are supported when configuring an ACL based RP assignment.

Displaying the static RP

Use the **show ip pim rp-set** command to display static RP and the associated group ranges.

```
Brocade(config)# show ip pim rp-set
Static RP and associated group ranges
-----
Static RP count: 4
130.1.1.1
120.1.1.1
120.2.1.1

Number of group prefixes Learnt from BSR: 0
No RP-Set present.
```

Use the **show ip pim rp-map** command to display all current multicast group addresses to RP address mapping.

```
Brocade(config)# show ip pim rp-map
Number of group-to-RP mappings: 5
      Group address      RP address
-----
1  230.0.0.1             100.1.1.1
2  230.0.0.2             100.1.1.1
3  230.0.0.3             100.1.1.1
4  230.0.0.4             100.1.1.1
5  230.0.0.5             100.1.1.1
```

Anycast RP

Anycast RP is a method of providing intra-domain redundancy and load-balancing between multiple Rendezvous Points (RP) in a Protocol Independent Multicast Sparse mode (PIM-SM) network. It is accomplished by configuring all RPs within a domain with the same anycast RP address which is typically a loopback IP address. Multicast Source Discovery Protocol (MSDP) is used between all of the RPs in a mesh configuration to keep all RPs in sync regarding the active sources.

PIM-SM routers are configured to register (statically or dynamically) with the RP using the same anycast RP address. Since multiple RPs have the same anycast address, an Interior Gateway Protocol (IGP) such as OSPF routes the PIM-SM router to the RP with the best route. If the PIM-SM routers are distributed evenly throughout the domain, the loads on RPs within the domain will be distributed. If the RP with the best route goes out of service, the PIM-SM router IGP changes the route to the closest operating RP that has the same anycast address.

This configuration works because MSDP is configured between all of the RPs in the domain. Consequently, all of the RPs share information about active sources.

Configuring Anycast RP

To configure Anycast RP, you must do the following:

- Configure a loopback interface with the anycast RP address on each of the RPs within the domain and enable PIM-SM on these interfaces.
- Ensure that the anycast RP address is leaked into the IGP domain. This is typically done by enabling the IGP on the loopback interface (in passive mode) or redistributing the connected loopback IP address into the IGP.

NOTE

The anycast RP address must not be the IGP router-id.

- Enable PIM-SM on all interfaces on which multicast routing is desired.
- Enable an IGP on each of the loopback interfaces and physical interfaces configured for PIM-SM.
- Configure loopback interfaces with unique IP addresses on each of the RPs for MSDP peering. This loopback interface is also used as the MSDP originator-id.
- The non-RP PIM-SM routers may be configured to use the anycast RP address statically or dynamically (by the PIMv2 bootstrap mechanism).

Example of a simple Anycast-enabled network

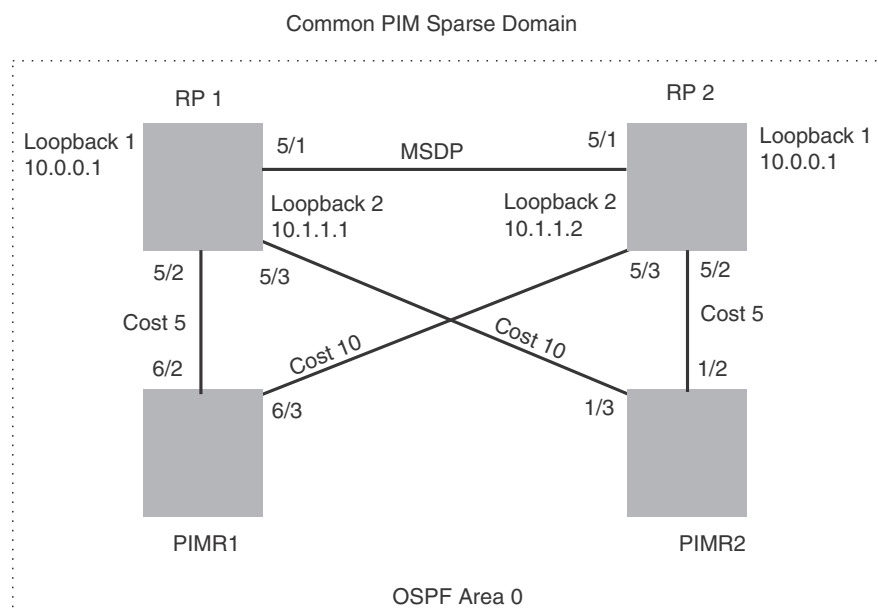

The example shown in Figure 175 is a simple Anycast-enabled network with two RPs and two PIM-SM routers. Loopback 1 in RP 1 and RP 2 have the same IP address. Loopback 2 in RP1 and Loopback 2 in RP2 have different IP addresses and are configured as MSDP peering IP addresses in a mesh configuration.

In the PIM configuration for PIM-SM routers PIMR1 and PIMR2 the RP address is configured to be the anycast RP address that was configured on the Loopback 1 interfaces on RP1 and RP2. OSPF is configured as the IGP for the network and all of the devices are in OSPF area 0.

Since PIMR1 has a lower cost path to RP1 and PIMR2 has a lower cost path to RP2 they will register with the respective RPs when both are up and running. This shares the load between the two RPs. If one of the RPs fails, the higher-cost path to the IP address of Loopback 1 on the RPs is used to route to the still-active RP.

The configuration examples demonstrate the commands required to enable this application.

FIGURE 175 Example of an Anycast RP network

RP 1 configuration

The following commands provide the configuration for the RP 1 router in [Figure 175](#).

```

Brocade RP1(config)#router ospf
Brocade RP1(config-ospf-router)# area 0
Brocade RP1(config-ospf-router)# exit
Brocade RP1(config)# interface loopback 1
Brocade RP1(config-lbif-1)# ip ospf area 0
Brocade RP1(config-lbif-1)# ip ospf passive
Brocade RP1(config-lbif-1)# ip address 10.0.0.1/32
Brocade RP1(config-lbif-1)# ip pim-sparse
Brocade RP1(config-lbif-1)# exit
Brocade RP1(config)# interface loopback 2
Brocade RP1(config-lbif-2)# ip ospf area 0
Brocade RP1(config-lbif-2)# ip ospf passive
Brocade RP1(config-lbif-2)# ip address 10.1.1.1/32
Brocade RP1(config-lbif-2)# exit
Brocade RP1(config)# interface ethernet 5/1
Brocade RP1(config-if-e1000-5/1)# ip ospf area 0
Brocade RP1(config-if-e1000-5/1)# ip address 192.1.1.1/24
Brocade RP1(config-if-e1000-5/1)# ip pim-sparse
Brocade RP1(config)# interface ethernet 5/2
Brocade RP1(config-if-e1000-5/2)# ip ospf area 0
Brocade RP1(config-if-e1000-5/2)# ip ospf cost 5
Brocade RP1(config-if-e1000-5/2)# ip address 192.2.1.1/24
Brocade RP1(config-if-e1000-5/2)# ip pim-sparse
Brocade RP1(config)# interface ethernet 5/3
Brocade RP1(config-if-e1000-5/3)# ip ospf area 0
Brocade RP1(config-if-e1000-5/3)# ip ospf cost 10
Brocade RP1(config-if-e1000-5/3)# ip address 192.3.1.1/24
Brocade RP1(config-if-e1000-5/3)# ip pim-sparse
Brocade RP1(config-if-e1000-5/3)# exit
Brocade RP1(config)# router pim
Brocade RP1(config-pim-router)# rp-candidate loopback 1
Brocade RP1(config-pim-router)# exit
Brocade RP1(config)# router msdp
Brocade RP1(config-msdp-router)# msdp-peer 10.1.1.2 connect-source loopback 2
Brocade RP1(config-msdp-router)# originator-id loopback 2

```

RP 2 configuration

The following commands provide the configuration for the RP 2 router in [Figure 175](#).

```

Brocade RP2(config)#router ospf
Brocade RP2(config-ospf-router)# area 0
Brocade RP2(config-ospf-router)# exit
Brocade RP2(config)# interface loopback 1
Brocade RP2(config-lbif-1)# ip ospf area 0
Brocade RP2(config-lbif-1)# ip ospf passive
Brocade RP2(config-lbif-1)# ip address 10.0.0.1/32
Brocade RP2(config-lbif-1)# ip pim-sparse
Brocade RP2(config-lbif-1)# exit
Brocade RP2(config)# interface loopback 2
Brocade RP2(config-lbif-2)# ip ospf area 0
Brocade RP2(config-lbif-2)# ip ospf passive
Brocade RP2(config-lbif-2)# ip address 10.1.1.2/32
Brocade RP2(config-lbif-2)# exit
Brocade RP2(config)# interface ethernet 5/1
Brocade RP2(config-if-e1000-5/1)# ip ospf area 0
Brocade RP2(config-if-e1000-5/1)# ip address 192.1.1.2/24

```

```

Brocade RP2(config-if-e1000-5/1)# ip pim-sparse
Brocade RP2(config)# interface ethernet 5/2
Brocade RP2(config-if-e1000-5/2)# ip ospf area 0
Brocade RP2(config-if-e1000-5/2)# ip ospf cost 5
Brocade RP2(config-if-e1000-5/2)# ip address 192.5.2.1/24
Brocade RP2(config-if-e1000-5/2)# ip pim-sparse
Brocade RP2(config)# interface ethernet 5/3
Brocade RP2(config-if-e1000-5/3)# ip ospf area 0
Brocade RP2(config-if-e1000-5/3)# ip ospf cost 10
Brocade RP2(config-if-e1000-5/3)# ip address 192.6.1.2/24
Brocade RP2(config-if-e1000-5/3)# ip pim-sparse
Brocade RP2(config-if-e1000-5/3)# exit
Brocade RP2(config)# router pim
Brocade RP2(config-pim-router)# rp-candidate loopback 1
Brocade RP2(config-pim-router)# exit
Brocade RP2(config)# router msdp
Brocade RP2(config-msdp-router)# msdp-peer 10.1.1.1 connect-source loopback 2
Brocade RP2(config-msdp-router)# originator-id loopback 2

```

PIMR1configuration

The following commands provide the configuration for the PIMR1 router in [Figure 175](#).

```

Brocade PIMR1(config)#router ospf
Brocade PIMR1(config-ospf-router)# area 0
Brocade PIMR1(config-ospf-router)# exit
Brocade PIMR1(config)# interface ethernet 6/2
Brocade PIMR1(config-if-e1000-6/2)# ip ospf area 0
Brocade PIMR1(config-if-e1000-6/2)# ip ospf cost 5
Brocade PIMR1(config-if-e1000-6/2)# ip address 192.2.1.2/24
Brocade PIMR1(config-if-e1000-6/2)# ip pim-sparse
Brocade PIMR1(config)# interface ethernet 6/3
Brocade PIMR1(config-if-e1000-6/3)# ip ospf area 0
Brocade PIMR1(config-if-e1000-6/3)# ip ospf cost 10
Brocade PIMR1(config-if-e1000-6/3)# ip address 192.6.1.1/24
Brocade PIMR1(config-if-e1000-6/3)# ip pim-sparse
Brocade PIMR1(config-if-e1000-6/3)# exit
Brocade PIMR1(config)# router pim
Brocade PIMR1(config-pim-router)# rp-address 10.0.0.1
Brocade PIMR1(config-pim-router)# exit

```

PIMR2 configuration

The following commands provide the configuration for the PIMR2 router in [Figure 175](#).

```

Brocade PIMR2(config)#router ospf
Brocade PIMR2(config-ospf-router)# area 0
Brocade PIMR2(config-ospf-router)# exit
Brocade PIMR2(config)# interface ethernet 1/2
Brocade PIMR2(config-if-e1000-1/2)# ip ospf area 0
Brocade PIMR2(config-if-e1000-1/2)# ip ospf cost 5
Brocade PIMR2(config-if-e1000-1/2)# ip address 192.5.2.2/24
Brocade PIMR2(config-if-e1000-1/2)# ip pim-sparse
Brocade PIMR2(config)# interface ethernet 1/3
Brocade PIMR2(config-if-e1000-1/3)# ip ospf area 0
Brocade PIMR2(config-if-e1000-1/3)# ip ospf cost 10
Brocade PIMR2(config-if-e1000-1/3)# ip address 192.3.1.2/24
Brocade PIMR2(config-if-e1000-1/3)# ip pim-sparse

```

PIM Sparse

```
Brocade PIMR2(config-if-e1000-1/3)# exit
Brocade PIMR2(config)# router pim
Brocade PIMR2(config-pim-router)# rp-address 10.0.0.1
Brocade PIMR2(config-pim-router)# exit
```

Displaying PIM Sparse configuration information and statistics

You can display the following PIM Sparse information:

- Basic PIM Sparse configuration information
- Group information
- BSR information
- Candidate RP information
- RP-to-group mappings
- RP information for a PIM Sparse group
- RP set list
- PIM Neighbor information
- The PIM flow cache
- The PIM multicast cache
- PIM traffic statistics

Displaying basic PIM Sparse configuration information

To display basic configuration information for PIM Sparse, enter the **show ip pim sparse** command at any CLI level.

```
Brocade#show ip pim sparse
```

```
Global PIM Sparse Mode Settings
  Hello interval: 60, Neighbor timeout: 180
  Bootstrap Msg interval: 130, Candidate-RP Advertisement interval: 60
  Join/Prune interval: 60, SPT Threshold: 1
```

```
Interface e11/1
PIM Sparse
TTL Threshold: 1, Enabled, DR: 50.1.1.2 on e11/1
Local Address: 50.1.1.1
Neighbor:
  50.1.1.2
```

```
Interface v40
PIM Sparse
TTL Threshold: 1, Enabled, DR: itself
Local Address: 40.1.1.2
Neighbor:
  40.1.1.1
```

Syntax: show ip pim sparse

Table 255 shows the information displayed by the **show ip pim sparse** command.

TABLE 255 Output of the **show ip pim sparse** command

Field	Description
Global PIM Sparse mode settings	
Hello interval	How frequently the Layer 3 switch sends PIM Sparse hello messages to its PIM Sparse neighbors. This field show the number of seconds between hello messages. PIM Sparse routers use hello messages to discover one another.
Neighbor timeout	How many seconds the Layer 3 switch will wait for a hello message from a neighbor before determining that the neighbor is no longer present and removing cached PIM Sparse forwarding entries for the neighbor.
Bootstrap Msg interval	How frequently the BSR configured on the Layer 3 switch sends the RP set to the RPs within the PIM Sparse domain. The RP set is a list of candidate RPs and their group prefixes. A candidate RP group prefix indicates the range of PIM Sparse group numbers for which it can be an RP. NOTE: This field contains a value only if an interface on the Layer 3 switch is elected to be the BSR. Otherwise, the field is blank.
Candidate-RP Advertisement interval	How frequently the candidate PR configured on the Layer 3 switch sends candidate RP advertisement messages to the BSR. NOTE: This field contains a value only if an interface on the Layer 3 switch is configured as a candidate RP. Otherwise, the field is blank.
Join/Prune interval	How frequently the Layer 3 switch sends PIM Sparse Join/Prune messages for the multicast groups it is forwarding. This field show the number of seconds between Join/Prune messages. The Layer 3 switch sends Join/Prune messages on behalf of multicast receivers who want to join or leave a PIM Sparse group. When forwarding packets from PIM Sparse sources, the Layer 3 switch sends the packets only on the interfaces on which it has received join requests in Join/Prune messages for the source group. You can change the Join/Prune interval if needed. Refer to “Changing the PIM join and prune message interval” on page 1538.
SPT Threshold	The number of packets the Layer 3 switch sends using the path through the RP before switching to using the SPT path.
PIM Sparse interface information	
NOTE: You also can display IP multicast interface information using the show ip pim interface command. However, this command lists all IP multicast interfaces, including regular PIM (dense mode) and DVMRP interfaces. The show ip pim sparse command lists only the PIM Sparse interfaces.	
Interface	The type of interface and the interface number. The interface type can be one of the following: <ul style="list-style-type: none"> • Ethernet • VE The number is either a port number (and slot number if applicable) or the virtual interface (VE) number.
TTL Threshold	Following the TTL threshold value, the interface state is listed. The interface state can be one of the following: <ul style="list-style-type: none"> • Disabled • Enabled
Local Address	Indicates the IP address configured on the port or virtual interface.

Displaying a list of multicast groups

To display a list of the IP multicast groups the Layer 3 switch is forwarding, enter the **show ip pim group** command at any CLI level.

```
Brocade#show ip pim group
```

```
Total number of Groups: 2
Index 1          Group 239.255.162.1      Ports e3/11
```

Syntax: **show ip pim group**

This display shows the following information.

TABLE 256 Output of show ip pim group

Field	Description
Total number of Groups	Lists the total number of IP multicast groups the Layer 3 switch is forwarding. NOTE: This list can include groups that are not PIM Sparse groups. If interfaces on the Layer 3 switch are configured for regular PIM (dense mode) or DVMRP, these groups are listed too.
Index	The index number of the table entry in the display.
Group	The multicast group address
Ports	The Layer 3 switch ports connected to the receivers of the groups.

Displaying BSR information

To display BSR information, enter the **show ip pim bsr** command at any CLI level.

```
Brocade#show ip pim bsr
```

```
PIMv2 Bootstrap information
```

```
This system is the elected Bootstrap Router (BSR)
  BSR address: 207.95.7.1
  Uptime: 00:33:52, BSR priority: 5, Hash mask length: 32
  Next bootstrap message in 00:00:20
```

```
Next Candidate-RP-advertisement in 00:00:10
  RP: 207.95.7.1
    group prefixes:
      224.0.0.0 / 4
Candidate-RP-advertisement period: 60
```

This example shows information displayed on a Layer 3 switch that has been elected as the BSR. The following example shows information displayed on a Layer 3 switch that is not the BSR. Notice that some fields shown in the example above do not appear in the example below.

```
Brocade#show ip pim bsr
```

```
PIMv2 Bootstrap information, state=ELECTED-BSR
  local BSR address = 99.99.99.5, age=0
  local BSR priority = 255
```

Syntax: **show ip pim bsr**

Table 257 shows the information displayed for the **show ip pim bsr** command.

TABLE 257 Output of **show ip pim bsr**

Field	Description
BSR address or local BSR address	The IP address of the interface configured as the PIM Sparse Bootstrap Router (BSR). NOTE: If the word “local” does not appear in the field, this Layer 3 switch is the BSR. If the word “local” does appear, this Layer 3 switch is not the BSR.
Uptime	The amount of time the BSR has been running. NOTE: This field appears only if this Layer 3 switch is the BSR.
BSR priority or local BSR priority	The priority assigned to the interface for use during the BSR election process. During BSR election, the priorities of the candidate BSRs are compared and the interface with the highest BSR priority becomes the BSR. NOTE: If the word “local” does not appear in the field, this Layer 3 switch is the BSR. If the word “local” does appear, this Layer 3 switch is not the BSR.
Hash mask length	The number of significant bits in the IP multicast group comparison mask. This mask determines the IP multicast group numbers for which the Layer 3 switch can be a BSR. The default is 32 bits, which allows the Layer 3 switch to be a BSR for any valid IP multicast group number. NOTE: This field appears only if this Layer 3 switch is the BSR.
Next bootstrap message in	Indicates how many seconds will pass before the BSR sends its next Bootstrap message. NOTE: This field appears only if this Layer 3 switch is the BSR.
Next Candidate-PR-advertisement message in	Indicates how many seconds will pass before the BSR sends its next candidate PR advertisement message. NOTE: This field appears only if this Layer 3 switch is the BSR.
RP	Indicates the IP address of the Rendezvous Point (RP). NOTE: This field appears only if this Layer 3 switch is the BSR.
group prefixes	Indicates the multicast groups for which the RP listed by the previous field is a candidate RP. NOTE: This field appears only if this Layer 3 switch is the BSR.
Candidate-RP-advertisement period	Indicates how frequently the BSR sends candidate RP advertisement messages. NOTE: This field appears only if this Layer 3 switch is the BSR.

Displaying PIM resources

To display the hardware resource information such as hardware allocation, availability, and limit for software data structure, enter the **show ip pim resource** command.

```
Brocade#show ip pim resource
```

	alloc	in-use	avail	get-fail	limit	get-mem	size	init

Syntax: show ip pim resource

Table 258 shows the information displayed for each software data structure listed in the output of the **show ip pim resource** command.

TABLE 258 Output of **show ip pim resource**

Field	Description
alloc	Number of nodes of that data that are currently allocated in memory.
in-use	Number of allocated nodes in use
avail	Number of allocated nodes are not in use
get-fail	Number of allocated notes that failed
limit	Maximum number of nodes that can be allocated for a data structure. This may or may not be configurable, depending on the data structure
get-mem	Number of attempts made to use allocated nodes
size	Memory size (in bytes) of the given resource.
init	Initial allocated pool size of the given resource.
#of PIM ports	Total number of PIM ports, by port type, on the device
Total, allocated, and available Mlls	In Layer 3 multicast, this refers to the Multicast Linked List that contains information on where (S,G) gets forwarded. Each (S,G) entry requires a single MLL entry to forward traffic to all physical, untagged ports. Also, one MLL entry is required per VLAN that has tagged outbound ports. There can be up to 1024 MLL entries.

NOTE

When the product of the number of active PIM interfaces multiplied by the number of multicast streams exceeds the total number of MLL, the CLI displays the message, “MLL pool out of memory”.

NOTE

The total number of MLL available changes according to the hardware configuration.

Displaying candidate RP information

To display candidate RP information, enter the **show ip pim rp-candidate** command at any CLI level.

```
Brocade#show ip pim rp-candidate

Next Candidate-RP-advertisement in 00:00:10
  RP: 198.168.1.160
    group prefixes:
      224.0.0.0 / 4

Candidate-RP-advertisement period: 60
```

This example show information displayed on a Layer 3 switch that is a candidate RP. The following example shows the message displayed on a Layer 3 switch that is not a candidate RP.

```
Brocade#show ip pim rp-candidate

This system is not a Candidate-RP.
```

Syntax: **show ip pim rp-candidate**

Table 259 shows the information displayed by the **show ip pim rp-candidate** command.

TABLE 259 Output of `show ip pim rp-candidate`

Field	Description
Candidate-RP-advertisement in	Indicates how many seconds will pass before the BSR sends its next RP message. NOTE: This field appears only if this Layer 3 switch is a candidate RP.
RP	Indicates the IP address of the Rendezvous Point (RP). NOTE: This field appears only if this Layer 3 switch is a candidate RP.
group prefixes	Indicates the multicast groups for which the RP listed by the previous field is a candidate RP. NOTE: This field appears only if this Layer 3 switch is a candidate RP.
Candidate-RP-advertisement period	Indicates how frequently the BSR sends candidate RP advertisement messages. NOTE: This field appears only if this Layer 3 switch is a candidate RP.

Displaying RP-to-group mappings

To display RP-to-group-mappings, enter the **show ip pim rp-map** command at any CLI level.

```
Brocade#show ip pim rp-map
Number of group-to-RP mappings: 1

Group address      RP address      age
-----
1 239.200.1.1      192.168.98.212  0
```

Syntax: `show ip pim rp-map`

[Table 260](#) shows the information displayed by the **show ip pim rp-map** command.

TABLE 260 Output of `show ip pim rp-map`

Field	Description
Group address	Indicates the PIM Sparse multicast group address using the listed RP.
RP address	Indicates the IP address of the Rendezvous Point (RP) for the listed PIM Sparse group.

Displaying RP information for a PIM Sparse group

To display RP information for a PIM Sparse group, enter the **show ip pim rp-hash** command at any CLI level.

```
Brocade#show ip pim rp-hash 225.0.0.15

RP: 192.168.1.160, version 2
Info source: 192.168.1.160, via bootstrap
```

Syntax: `show ip pim rp-hash <group-addr>`

The `<group-addr>` parameter is the address of a PIM Sparse IP multicast group.

Table 261 shows the information displayed by the **show ip pim rp-hash** command.

TABLE 261 Output of **show ip pim rp-hash**

Field	Description
RP	Indicates the IP address of the Rendezvous Point (RP) for the specified PIM Sparse group. Following the IP address is the method through which this Layer 3 Switch learned the identity of the RP.
Info source	Indicates the IP address on which the RP information was received. Following the IP address is the method through which this Layer 3 switch learned the identity of the RP.

Displaying the RP set list

To display the RP set list, enter the **show ip pim rp-set** command at any CLI level.

```
router(config)#show ip pim rp-set
No static-RP configured

BSR state=ELECTED-BSR, # of group prefixes Learntn from BSR: 1

Group prefix=224.0.0.0/4      #RPs:1
    RP1:192.168.1.160      priority=0, age=30, holdtime=150
```

Syntax: **show ip pim rp-set**

Table 262 shows the information displayed by the **show ip pim rp-set** command.

TABLE 262 Output of **show ip pim rp-set**

Field	Description
Number of group prefixes	The number of PIM Sparse group prefixes for which the RP is responsible.
Group prefix	Indicates the multicast groups for which the RP listed by the previous field is a candidate RP.
RP <num>	Indicates the RP number. If there are multiple RPs in the PIM Sparse domain, a line of information for each of them is listed, and they are numbered in ascending numerical order.
priority	The RP priority of the candidate RP. During the election process, the candidate RP with the highest priority is elected as the RP.
age	The age (in seconds) of this RP-set. NOTE: If this Layer 3 switch is not a BSR, this field contains zero. Only the BSR ages the RP-set.
holdtime	Holdtime indicates the time allowed by the Bootstrap Router (BSR) before timing out RPs. If the BSR does not receive a candidate RP advertisement from an RP within the holdtime, the BSR removes that router from its list of candidate RPs.

Displaying multicast neighbor information

To display information about the Layer 3 switch PIM neighbors, enter the **show ip pim neighbor** command at any CLI level.

```
Brocade#show ip pim neighbor
Total number of neighbors: 250 on 1 ports
Port   Phy_p   Neighbor Holdtime   Age   UpTime  GenID
v101   3/1/12  173.1.1.2 180        60    17144   0x2CB53BBB
Port   Phy_p   Neighbor Holdtime   Age   UpTime  GenID
v102   3/1/11  173.1.2.2 180        60    17144   0x26976038
Port   Phy_p   Neighbor Holdtime   Age   UpTime  GenID
v103   3/1/13  173.1.3.2 180        60    17084   0x7F6E7643
Port   Phy_p   Neighbor Holdtime   Age   UpTime  GenID
v104   2/1/11  173.1.4.2 180        60    17144   0x6A014EB4
Port   Phy_p   Neighbor Holdtime   Age   UpTime  GenID
v105   2/1/12  173.1.5.2 180        60    17144   0x14FF45A1
```

Syntax: **show ip pim neighbor**

[Table 263](#) shows the information displayed by the **show ip pim neighbor** command.

TABLE 263 Output of **show ip pim neighbor**

Field	Description
Port	The interface through which the Layer 3 switch is connected to the neighbor.
Neighbor	The IP interface of the PIM neighbor interface.
Holdtime	Indicates how many seconds the neighbor wants this Layer 3 switch to hold the entry for this neighbor in memory. The neighbor sends the Hold Time in its Hello packets: <ul style="list-style-type: none"> If the Layer 3 switch receives a new Hello packet before the Hold Time received in the previous packet expires, the Layer 3 switch updates its table entry for the neighbor. If the Layer 3 switch does not receive a new Hello packet from the neighbor before the Hold time expires, the Layer 3 switch assumes the neighbor is no longer available and removes the entry for the neighbor.
Age	The number of seconds since the Layer 3 switch received the last hello message from the neighbor.
UpTime	The number of seconds the PIM neighbor has been up. This timer starts when the Layer 3 switch receives the first Hello messages from the neighbor.
GenID	The Generation ID of the neighbor's Hello messages.

Displaying information about an upstream neighbor device

You can view information about the upstream neighbor device for a given source IP address for IP PIM and DVMRP. The software uses the IP route table or multicast route table to lookup the upstream neighbor device. For DVMRP, the software uses the DVMRP route table to locate the upstream neighbor device.

Enter the **show ip pim rpf** command at the Privileged EXEC level of the CLI.

```
Brocade#show ip pim rpf 172.10.1.5 225.0.0.19
PIM sparse mcache of (172.10.1.5, 225.0.0.19) is used in RPF lookup
Upstream neighbor=40.1.1.1 on v40 using ip route
```

Syntax: `show ip pim | dvmrp rpf <IP address>`

where <IP address> is a valid source IP address.

NOTE

If there are multiple equal cost paths to the source, the `show ip pim rpf` command output may not be accurate. If your system has multiple equal cost paths, use the command `show ip pim mcache` to view information about the upstream neighbor.

Displaying the PIM flow cache

To display the PIM flow cache, enter the following command at any CLI level.

```
Brocade #show ip pim flowcache 228.2.2.2
```

```
Outbound Ports for Multicast flow (12.12.12.1 228.2.2.2):  
L2 : None
```

```
L3 :  
    Tagged Port in Vlan 1 : ethe 3/14
```

```
Outbound Ports for Multicast flow (0.0.0.0 228.2.2.2):  
L2 : 8192  
Hardware MC Entry not found
```

```
2 flow printed
```

Syntax: `show ip pim flowcache`

In the above output of the `show ip pim flowcache` command, ethe 3/14 is the outbound interface on which the multicast traffic is being sent out.

Displaying the PIM multicast cache

To display the PIM multicast cache, enter the **show ip pim mcache** command at any CLI level.

```
Brocade#show ip pim mcache
Total 2 entries
Example: (S G) in v40 (e2/3) cnt= : e2/3 is phy. of input v40, cnt: SW hit incl.
drop
HW: CAM switched, SW: cpu switched, OAR: SW one?arm?routing, VL: vlan
trunking: TR(e3/3,e3/4): e3/3 is primary trunk port, e3/4 is real out p.
FLAGS: fast/slow: could be HW switched or not
      pruned from upstream
      frag: packet fragmented, SW forwarded unless multicast?perf configured
      tag/tnnl: OIF has tagged/tunnel ports
      swL2/hwL2: SW or HW L2 forwarding
      age: send 1 pkt to cpu from HW switch to reset age
      0L2C: no L2 CAM hash
      ClSr: has client on input port, never send prune even OIF empty
      drop: use cam to drop pkts if no OIFs.

1      (173.21.1.13 239.200.1.1) in 1/2/4 (1/2/4), cnt=109
      Source is directly connected
      Sparse Mode, RPT=0 SPT=1 REG=0 MSDP Adv=1 MSDP Create=0
      L3 (HW) 1: tag TR(1/1/11,2/1/12)(VL101)
      fast=1 slow=0 pruned=0 graft age
      age=60s up-time=7m HW=1 L2?vidx=4131 has mll

2      (* 239.200.1.1) RP 192.168.98.212, in NIL (NIL), cnt=0
      No upstream neighbor because RP 192.168.98.212 is itself
      Sparse Mode, RPT=1 SPT=0 REG=0 MSDP Adv=0 MSDP Create=0
      L3 (SW) 1: tag TR(1/1/11,1/1/11)(VL101)
      fast=1 slow=0 pruned=1 graft
      age=0s up-time=1379m HW=0
```

Syntax: **show ip pim mcache**

Table 264 shows the information displayed by the **show ip pim mcache** command.

TABLE 264 Output of **show ip pim mcache**

Field	Description
(<source>, <group>)	The comma-separated values in parentheses is a source-group pair. The <source> is the PIM source for the multicast <group>. For example, the following entry means source 209.157.24.162 for group 239.255.162.1: (209.157.24.162,239.255.162.1) If the <source> value is * (asterisk), this cache entry uses the RP path. The * value means "all sources". If the <source> is a specific source address, this cache entry uses the SPT path.
RP<ip-addr>	Indicates the RP for the group for this cache entry. NOTE: The RP address appears only if the RPT flag is set to 1 and the SPT flag is set to 0 (see below).
forward port	The port through which the Layer 3 switch reaches the source.
Count	The number of packets forwarded using this cache entry.

TABLE 264 Output of **show ip pim mcache** (Continued)

Field	Description
Sparse Mode	Indicates whether the cache entry is for regular PIM (dense mode) or PIM Sparse. This flag can have one of the following values: <ul style="list-style-type: none"> 0 – The entry is not for PIM Sparse (and is therefore for the dense mode of PIM). 1 – The entry is for PIM Sparse.
RPT	Indicates whether the cache entry uses the RP path or the SPT path. The RPT flag can have one of the following values: <ul style="list-style-type: none"> 0 – The SPT path is used instead of the RP path. 1 – The RP path is used instead of the SPT path. NOTE: The values of the RP and SPT flags are always opposite (one is set to 0 and the other is set to 1).
SPT	Indicates whether the cache entry uses the RP path or the SPT path. The SP flag can have one of the following values: <ul style="list-style-type: none"> 0 – The RP path is used instead of the SPT path. 1 – The SPT path is used instead of the RP path. NOTE: The values of the RP and SPT flags are always opposite (one is set to 0 and the other is set to 1).
Register Suppress	Indicates whether the Register Suppress timer is running. This field can have one of the following values: <ul style="list-style-type: none"> 0 – The timer is not running. 1 – The timer is running.
member ports	Indicates the Layer 3 switch physical ports to which the receivers for the source and group are attached. The receivers can be directly attached or indirectly attached through other PIM Sparse routers.
virtual ports	Indicates the virtual interfaces to which the receivers for the source and group are attached. The receivers can be directly attached or indirectly attached through other PIM Sparse routers.
prune ports	Indicates the physical ports on which the Layer 3 switch has received a prune notification (in a Join/Prune message) to remove the receiver from the list of recipients for the group.
virtual prune ports	Indicates the virtual interfaces ports on which the Layer 3 switch has received a prune notification (in a Join/Prune message) to remove the receiver from the list of recipients for the group.

Displaying PIM traffic statistics

To display PIM traffic statistics, enter the **show ip pim traffic** command.

```
Brocade#show ip pim traffic
```

Port	Hello		J/P		Register		RegStop		Assert	
	[Rx]	[Tx]	[Rx]	[Tx]	[Rx]	[Tx]	[Rx]	[Tx]	[Rx]	[Tx]
1/2/4	0	8691	0	0	0	0	0	0	0	0
v24	0	1383	0	0	0	0	0	0	0	0
v25	0	1383	0	0	0	0	0	0	0	0
v101	44745	10091	21851	0	0	0	0	0	0	0
v102	41556	10024	0	0	0	0	0	0	0	0
v103	28035	10005	0	0	0	0	0	0	0	0

IGMP Statistics:

Total Recv/Xmit 2488418/11787722

Syntax: **show ip pim traffic**

NOTE

If you have configured interfaces for standard PIM (dense mode) on the Layer 3 switch, statistics for these interfaces are listed first by the display.

This display shows the following information.

TABLE 265 Output of show ip pim traffic

Field	Description
Port	The port or virtual interface on which the PIM interface is configured.
Hello	The number of PIM Hello messages sent or received on the interface.
J/P	The number of Join/Prune messages sent or received on the interface. NOTE: Unlike PIM dense, PIM Sparse uses the same messages for Joins and Prunes.
Register	The number of Register messages sent or received on the interface.
RegStop	The number of Register Stop messages sent or received on the interface.
Assert	The number of Assert messages sent or received on the interface.
Total Recv/Xmit	The total number of IGMP messages sent and received by the Layer 3 switch.
Total Discard/chksum	The total number of IGMP messages discarded, including a separate counter for those that failed the checksum comparison.

Clearing the PIM message counters

You can clear the PIM message counters using the **clear pim traffic** command.

```
Brocade# clear pim traffic
```

Syntax: clear pim traffic

Displaying and clearing PIM errors

If you want to determine how many PIM errors there are on the device, enter the **show ip pim error** command.

```
Brocade# show ip pim error
**** Warning counter pim route change = 1
HW tagged replication enabled, SW processed pkts 0
```

Syntax: show ip pim error

This command displays the number of warnings and non-zero PIM errors on the device. This count can increase during transition periods such as reboots and topology changes; however, if the device is stable, the number of errors should not increase. If warnings keep increasing in a stable topology, then there may be a configuration error or problems on the device.

To clear the counter for PIM errors, enter the **clear pim counters** command.

```
Brocade#clear pim counters
```

Syntax: clear pim counters

PIM Passive

PIM Passive is used to reduce and minimize unnecessary PIM Hello and other PIM control messages.

PIM Passive allows you to specify that the interface is “passive” in regards to PIM. No PIM control packets are sent or processed (if received), but hosts can still send and receive multicast traffic and IGMP control traffic on that interface. Also, PIM Passive prevents any malicious router from taking over as the designated router (DR), which can prevent all hosts on the LAN from joining multicast traffic outside the LAN.

The following guidelines apply to PIM Passive:

1. This is a Layer 3 interface [Ethernet/Ve] level feature.
2. Since the loopback interfaces are never used to form PIM neighbors, this feature is not supported on loopback interface.
3. Both PIM SM and PIM DM modes support this feature.
4. Applying the PIM Passive on an interface requires PIM to be enabled on that interface.
5. The sent and received statistics of a PIM Hello message are not changed for an interface, while it is configured as PIM passive.

To enable PIM Passive on an interface, enter the following commands:

```
Brocade# config term
Brocade(config)#router pim
Brocade(config-pim-router)#exit
Brocade(config)#interface ethernet 2
Brocade(config-if-e1000-2)#ip pim
Brocade(config-if-e1000-2)#ip pim passive
Brocade(config-if-e1000-2)#exit
Brocade(config)#interface ve 2
Brocade(config-vif-2)#ip pim-sparse
Brocade(config-vif-2)#ip pim passive
Brocade(config-vif-2)#exit
```

Syntax: [no] ip pim passive3

Multicast Source Discovery Protocol (MSDP)

The Multicast Source Discovery Protocol (MSDP) is used by Protocol Independent Multicast (PIM) Sparse routers to exchange routing information for PIM Sparse multicast groups across PIM Sparse domains. Routers running MSDP can discover PIM Sparse sources that are in other PIM Sparse domains.

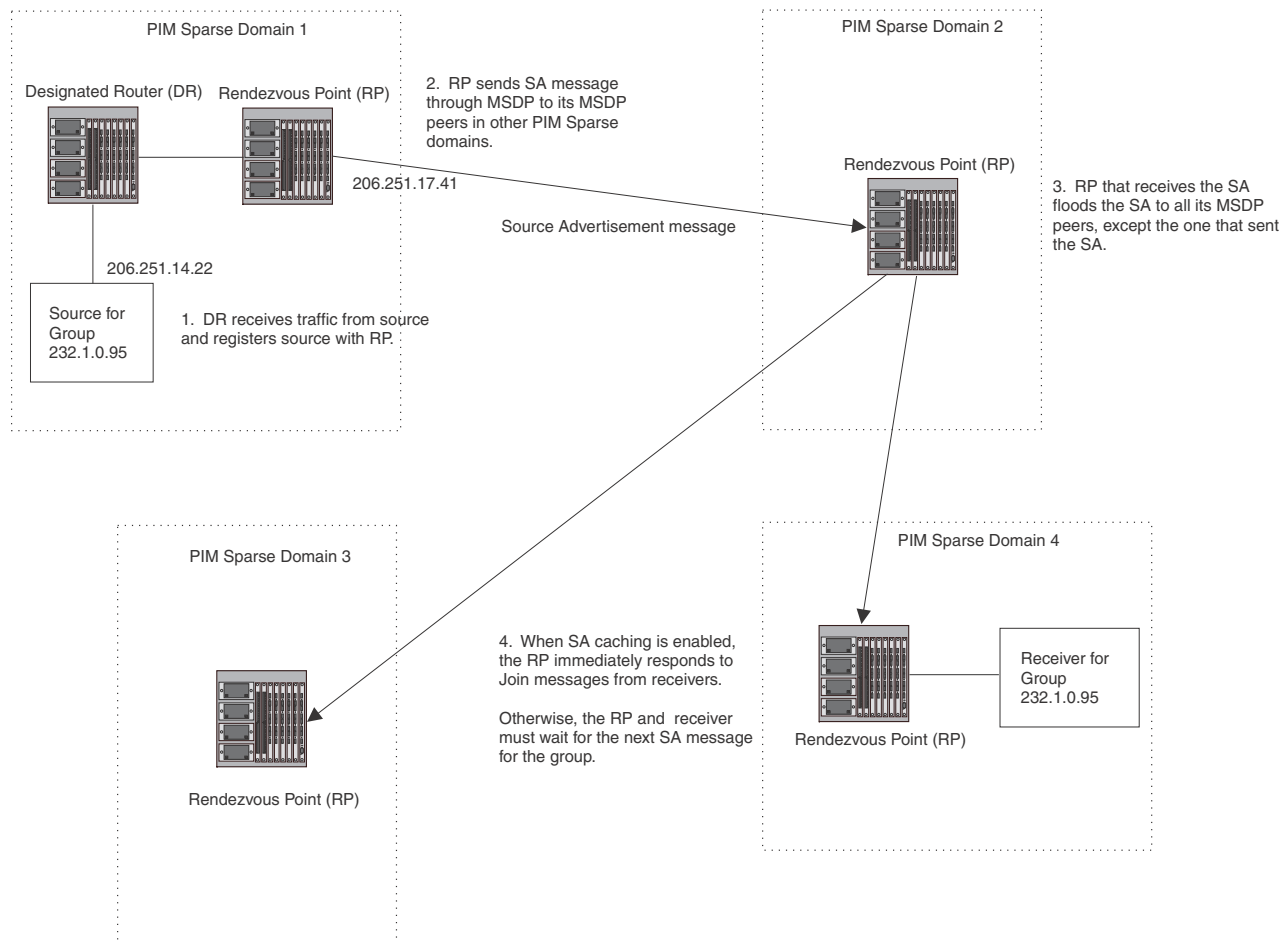

NOTE

MSDP is not supported on FCX and ICX platforms.

PIM Sparse routers use MSDP to register PIM Sparse multicast sources in a domain with the Rendezvous Point (RP) for that domain.

Figure 176 shows an example of some PIM Sparse domains. For simplicity, this example shows only one Designated Router (DR), one group source, and one receiver for the group. Only one PIM Sparse router within each domain needs to run MSDP.

FIGURE 176 PIM Sparse domains joined by MSDP routers

In this example, the source for PIM Sparse multicast group 232.0.1.95 is in PIM Sparse domain 1. The source sends a packet for the group to its directly attached DR. The DR sends a Group Advertisement message for the group to the domain RP. The RP is configured for MSDP, which enables the RP to exchange source information with other PIM Sparse domains by communicating with RPs in other domains that are running MSDP.

The RP sends the source information to each of its peers by sending a Source Active message. The message contains the IP address of the source, the group address to which the source is sending, and the IP address of the RP interface with its peer. By default, the IP address included in the RP address field of the SA message is the IP address of the originating RP. However, if MSDP is instructed to use a specific address as the IP address of the RP in a Source Address message (CLI command **originator-id** <type> <number>), the Source Active message can be the IP address of any interface on the originating RP. The interface is usually a loopback interface.

In this example, the Source Active message contains the following information:

- Source address: 206.251.14.22
- Group address: 232.1.0.95
- RP address: 206.251.17.41

Figure 176 shows only one peer for the MSDP router (which is also the RP here) in domain 1, so the Source Active message goes to only that peer. When an MSDP router has multiple peers, it sends a Source Active message to each of those peers. Each peer sends the Source Advertisement to its other MSDP peers. The RP that receives the Source Active message also sends a Join message for the group if the RP that received the message has receivers for the group.

Peer Reverse Path Forwarding (RPF) flooding

When the Multicast Source Discovery Protocol (MSDP) router (also the RP) in domain 2 receives the Source Active message from its peer in domain 1, the MSDP router in domain 2 forwards the message to all its other peers. The propagation process is sometimes called “peer Reverse Path Forwarding (RPF) flooding”. This term refers to the fact that the MSDP router uses its PIM Sparse RPF tree to send the message to its peers within the tree. In Figure 176, the MSDP router floods the Source Active message it receives from its peer in domain 1 to its other peers, in domains 3 and 4.

Note that the MSDP router in domain 2 does not forward the Source Active back to its peer in domain 1, because that is the peer from which the router received the message. An MSDP router never sends a Source Active message back to the peer that sent it. The peer that sent the message is sometimes called the “RPF peer”. The MSDP router uses the unicast routing table for its Exterior Gateway Protocol (EGP) to identify the RPF peer by looking for the route entry that is the next hop toward the source. Often, the EGP protocol is Border Gateway Protocol (BGP) version 4.

NOTE

MSDP depends on BGP for interdomain operations.

NOTE

MSDP is supported only on FSX devices.

The MSDP routers in domains 3 and 4 also forward the Source Active message to all their peers except the ones that sent them the message. Figure 176 does not show additional peers.

Source active caching

When the Multicast Source Discovery Protocol (MSDP) router that is also an RP receives a Source Active message, the RP checks its PIM Sparse multicast group table for receivers for the group. If the DR has a receiver for the group being advertised in the Source Active message, the DR sends a Join message for that receiver back to the DR in the domain from which the Source Active message came. Usually, the DR is also the MSDP router that sent the Source Active message.

In Figure 176, if the MSDP router and RP in domain 4 has a table entry for the receiver, the RP sends a Join message on behalf of the receiver back through the RPF tree to the RP for the source, in this case the RP in domain 1.

Some MSDP routers that are also RPs can cache Source Active messages. If the RP is not caching Source Active messages, the RP does not send a Join message unless it already has a receiver that wants to join the group. Otherwise, the RP does not send a Join message and does not remember the information in the Source Active message after forwarding it. If the RP receives a request from a receiver for the group, the RP and receiver must wait for the next Source Active message for that group before the RP can send a Join message for the receiver.

However, if Source Active caching is enabled on the MSDP and RP router, the RP caches the Source Active messages it receives. In this case, even if the RP does not have a receiver for a group when the RP receives the Source Active message for the group, the RP can immediately send a Join for a new receiver that wants to join the group, without waiting for the next Source Active message from the RP in the source domain.

The maximum size of the cache used to store MSDP Source Active messages is 8K and the default size is 4K.

MSDP configuration

To configure Multicast Source Discovery Protocol (MSDP) on a Layer 3 switch, perform the following tasks:

- Enable MSDP
- Configure the MSDP peers

NOTE

The PIM Sparse Rendezvous Point (RP) is also an MSDP peer.

NOTE

Routers that run MSDP must also run BGP. Also, the source address used by the MSDP router must be the same source address used by BGP.

Enabling MSDP

To enable MSDP, enter the **router msdp** command.

```
Brocade(config)# router msdp
```

NOTE

When enabling and disabling MSDP, you do not need to save the configuration and reload the software. The configuration change takes effect immediately, as soon as you enter the CLI command.

Syntax: [no] router msdp

Configuring MSDP peers

To configure an MSDP peer, enter the **msdp-peer** command at the MSDP configuration level.

```
Brocade(config-msdp-router)# msdp-peer 205.216.162.1
```

Syntax: [no] msdp-peer <ip-addr> [connect-source loopback <num>]

The <ip-addr> parameter specifies the IP address of the neighbor.

The **connect-source loopback <num>** parameter specifies the loopback interface you want to use as the source for sessions with the neighbor.

NOTE

It is strongly recommended that you use the **connect-source loopback <num>** parameter when issuing the **msdp-peer** command. If you do not use this parameter, the Layer 3 switch uses the subnet interface configured on the port.

Also, make sure the IP address of the connect-source loopback is the same as the source IP address used by the MSDP router, the PIM-RP, and the BGP router.

The commands in the following example add an MSDP neighbor and specify a loopback interface as the source interface for sessions with the neighbor. By default, the Layer 3 switch uses the subnet address configured on the physical interface where you configure the neighbor as the source address for sessions with the neighbor.

```
Brocade(config)# interface loopback 1
Brocade(config-lbif-1)# ip address 9.9.9.9/32
Brocade(config-lbif-1)#exit
Brocade(config)# router msdp
Brocade(config-msdp-router)# msdp-peer 2.2.2.99 connect-source loopback 1
```

Designating an interface IP address as the RP IP address

When an RP receives a Source Active message, it checks its PIM Sparse multicast group table for receivers for the group. If it finds a receiver, the RP sends a Join message for that receiver back to the RP that originated the Source Active message. The originator RP is identified by its RP address.

By default, the IP address included in the RP address field of the SA message is the IP address of the originating RP. Beginning with this release, an SA message can use the IP address of any interface on the originating RP. (The interface is usually a loopback interface.)

To designate an interface IP address to be the IP address of the RP, enter commands such as the following:

```
Brocade(config)# interface loopback 2
Brocade(config-lbif-2)# ip address 2.2.1.99/32
Brocade(config)# router msdp
Brocade(config-msdp-router)# originator-id loopback 2
Brocade(config-msdp-router)# exit
```

Syntax: [no] **originator-id** <type> <number>

The **originator-id** parameter instructs MSDP to use the specified address as the IP address of the RP in an SA message. This address must be the address of the interface used to connect the RP to the source. There are no default originator-ids.

The <type> parameter indicates the type of interface used by the RP. Ethernet, loopback and virtual routing interfaces (ve) can be used.

The <number> parameter specifies the interface number (for example: loopback number, port number or virtual routing interface number.)

Filtering MSDP source-group pairs

The following commands allow you to filter individual source-group pairs in MSDP Source-Active messages:

- **sa-filter in** – Filters source-group pairs received in Source-Active messages from an MSDP neighbor
- **sa-filter originate** – Filters source-group pairs in Source-Active messages in advertisements to an MSDP neighbor

Filtering incoming source-active messages

The following example configures filters for incoming Source-Active messages from three MSDP neighbors:

- For peer 2.2.2.99, all source-group pairs in Source-Active messages from the neighbor are filtered out (dropped).
- For peer 2.2.2.97, all source-group pairs except those with 10.x.x.x as the source are permitted.
- For peer 2.2.2.96, all source-group pairs except those associated with RP 2.2.42.3 are permitted.

Example of configuring MSDP peers

The following commands configure an IP address on port 3/1. This is the port on which the MSDP neighbors will be configured.

```
Brocade(config)# interface ethernet 3/1
Brocade(config-if-3/1)# ip address 2.2.2.98/24
Brocade(config-if-3/1)# exit
```

The following commands configure a loopback interface. The Layer 3 switch will use this interface as the source address for communicating with the MSDP neighbors.

```
Brocade(config)# interface loopback 1
Brocade(config-lbif-1)# ip address 9.9.9.8/32
Brocade(config-lbif-1)# exit
```

The following commands configure extended ACLs. The ACLs will be used in route maps, which will be used by the Source-Active filters.

```
Brocade(config)# access-list 123 permit 10.0.0.0 0.255.255.255 any
Brocade(config)# access-list 124 permit 2.2.42.3 0.0.0.0 any
Brocade(config)# access-list 125 permit any any
```

The following commands configure the route maps.

```
Brocade(config)# route-map msdp_map deny 1
Brocade(config-routemap msdp_map)# match ip address 123
Brocade(config-routemap msdp_map)# route-map msdp_map permit 10
Brocade(config-routemap msdp_map)# exit
Brocade(config)# route-map msdp2_map permit 1
Brocade(config-routemap msdp2_map)# match ip address 125
Brocade(config-routemap msdp2_map)# exit
Brocade(config)# route-map msdp2_rp_map deny 1
Brocade(config-routemap msdp2_rp_map)# match ip route-source 124
Brocade(config-routemap msdp2_rp_map)# route-map msdp2_rp_map permit 10
Brocade(config-routemap msdp2_rp_map)# exit
```

NOTE

The default action rule for **route-map** is to deny all routes that are not explicitly permitted. If you configure a “deny” route map but want to permit other routes that do not match the rule, configure an “empty” permit route map, as shown in the following example.

```
Brocade(config)#route-map abc deny 10
Brocade(config-route-map abc)#match metric 20
Brocade(config-route-map abc)#route-map abc permit 20
```

Without the last line in the above example, all routes would be denied.

The following commands enable MSDP and configure the MSDP neighbors on port 3/1.

```
Brocade(config)# router msdp
Brocade(config-msdp-router)# msdp-peer 2.2.2.99 connect-source loopback 1
Brocade(config-msdp-router)# msdp-peer 2.2.2.97 connect-source loopback 1
Brocade(config-msdp-router)# msdp-peer 2.2.2.96 connect-source loopback 1
Brocade(config-msdp-router)# exit
```

The following commands configure the Source-Active filters.

```
Brocade(config)# router msdp
Brocade(config-msdp-router)# sa-filter in 2.2.2.99
Brocade(config-msdp-router)# sa-filter in 2.2.2.97 route-map msdp_map
Brocade(config-msdp-router)# sa-filter in 2.2.2.96 route-map msdp2_map
rp-route-map msdp2_rp_map
```

The **sa-filter** commands configure the following filters:

- **sa-filter in 2.2.2.99** – This command drops all source-group pairs received from neighbor 2.2.2.99.

NOTE

The default action is to deny all source-group pairs from the specified neighbor. If you want to permit some pairs, use route maps.

- **sa-filter in 2.2.2.97 route-map msdp_map** – This command drops source-group pairs received from neighbor 2.2.2.97 if the pairs have source address 10.x.x.x and any group address.
- **sa-filter in 2.2.2.96 route-map msdp2_map rp-route-map msdp2_rp_map** – This command accepts all source-group pairs except those associated with RP 2.2.42.3.

Syntax: [no] **sa-filter** in <ip-addr> [route-map <map-tag>] [rp-route-map <rp-map-tag>]

The <ip-addr> parameter specifies the IP address of the MSDP neighbor. The filter applies to Active-Source messages received from this neighbor.

The **route-map <map-tag>** parameter specifies a route map. The Layer 3 switch applies the filter to source-group pairs that match the route map. Use the **match ip address <acl-id>** command in the route map to specify an extended ACL that contains the source and group addresses.

The **rp-route-map <rp-map-tag>** parameter specifies a route map to use for filtering based on Rendezvous Point (RP) address. Use this parameter if you want to filter Source-Active messages based on their origin. If you use the **route-map** parameter instead, messages are filtered based on source-group pairs but not based on origin. Use the **match ip route-source <acl-id>** command in the route map to specify the RP address.

NOTE

The default filter action is deny. If you want to permit some source-group pairs, use a route map. A permit action in the route map allows the Layer 3 switch to receive the matching source-group pairs. A deny action in the route map drops the matching source-group pairs.

Filtering advertised source-active messages

The following example configures the Layer 3 switch to advertise all source-group pairs except the ones that have source address 10.x.x.x.

Example of configuring source Active (SA) filters

The following commands configure an IP address on port 3/1. This is the port on which the MSDP neighbors will be configured.

```
Brocade(config)# interface ethernet 3/1
Brocade(config-if-3/1)# ip address 2.2.2.98/24
Brocade(config-if-3/1)# exit
```

The following commands configure a loopback interface. The Layer 3 switch will use this interface as the source address for communicating with the MSDP neighbors.

```
Brocade(config)# interface loopback 1
Brocade(config-lbif-1)# ip address 9.9.9.8/32
Brocade(config-lbif-1)# exit
```

The following command configures an extended ACL to specify the source and group addresses you want to filter.

```
Brocade(config)# access-list 123 permit 10.0.0.0 0.255.255.255 any
```

The following commands configure a route map. The map matches on source address 10.x.x.x and any group address. Since the action is deny, the Source-Active filter that uses this route map will remove the source-group pairs that match this route map from the Source-Active messages to the neighbor.

```
Brocade(config)# route-map msdp_map deny 1
Brocade(config-routemap msdp_map)# match ip address 123
Brocade(config-routemap msdp_map)# exit
```

The following commands enable MSDP and configure MSDP neighbors.

```
Brocade(config)# router msdp
Brocade(config-msdp-router)# msdp-peer 2.2.2.99 connect-source loopback 1
Brocade(config-msdp-router)# msdp-peer 2.2.2.97 connect-source loopback 1
Brocade(config-msdp-router)# exit
```

The following commands configure the Source-Active filter.

```
Brocade(config)# router msdp
Brocade(config-msdp-router)# sa-filter originate route-map msdp_map
```

This filter removes source-group pairs that match route map msdp_map from Source-Active messages before sending them to MSDP neighbors.

Syntax: [no] sa-filter originate [route-map <map-tag>]

The **route-map** *<map-tag>* parameter specifies a route map. The Layer 3 switch applies the filter to source-group pairs that match the route map. Use the **match ip address** *<acl-id>* command in the route map to specify an extended ACL that contains the source and group addresses.

NOTE

The default filter action is deny. If you want to permit some source-group pairs, use a route map. A permit action in the route map allows the Layer 3 switch to receive the matching source-group pairs. A deny action in the route map drops the matching source-group pairs.

MSDP mesh groups

A PIM Sparse domain can have several RPs that are connected to each other to form an MSDP mesh group. To qualify as a mesh group, the RPs have to be fully meshed; that is, each RP must be connected to all peer RPs in a domain. (See Figure 177.)

A mesh group reduces the forwarding of SA messages within a domain. Instead of having every RP in a domain forward SA messages to all the RPs within that domain, only one RP forwards the SA message. Since an MSDP mesh group is fully meshed, peers do not forward SA messages received in a domain from one member to every member of the group. The RP that originated the SA or the first RP in a domain that receives the SA message is the only one that can forward the message to the members of a mesh group. An RP can forward an SA message to any MSRP router as long as that peer is farther away from the originating RP than the current MSRP router.

Figure 177 shows an example of an MSDP mesh group. In a PIM-SM mesh group the RPs are configured to be peers of each other. They can also be peers of RPs in other domains.

Configuring an MSDP mesh group

To configure an MSDP mesh group, enter commands such as the following on each device that will be included in the mesh group:

```
Brocade(config)# router msdp
Brocade(config-msdp-router)# msdp-peer 1.1.3.1 connect-source loopback 1
Brocade(config-msdp-router)# msdp-peer 1.1.4.1 connect-source loopback 1
Brocade(config-msdp-router)# msdp-peer 1.1.2.1 connect-source loopback 1
Brocade(config-msdp-router)# msdp-peer 17.17.17.7
Brocade(config-msdp-router)# mesh-group 1234 1.1.4.1
Brocade(config-msdp-router)# mesh-group 1234 1.1.3.1
Brocade(config-msdp-router)# mesh-group 1234 1.1.2.1
Brocade(config-msdp-router)# exit
```

Syntax: [no] **mesh-group** *<group-name>* *<peer-address>*

The example configuration above reflects the configuration in Figure 177. On RP 1.1.1.1, you specify its peers within the same domain (1.1.3.1, 1.1.4.1, and 1.1.2.1).

You first configure the MSDP peers using the **msdp-peer** command to assign their IP addresses and the loopback interfaces. This information will be used as the source for sessions with the neighbor.

Next, place the MSDP peers within a domain into a mesh group. Use the **mesh-group** command. There are no default mesh groups.

The **group-name** parameter identifies the group. Enter up to 31 characters for group-name. You can have up to 4 mesh groups within a multicast network. Each mesh group can include up to 32 peers.

The **peer-address** parameter specifies the IP address of the MSDP peer that is being placed in the group.

NOTE

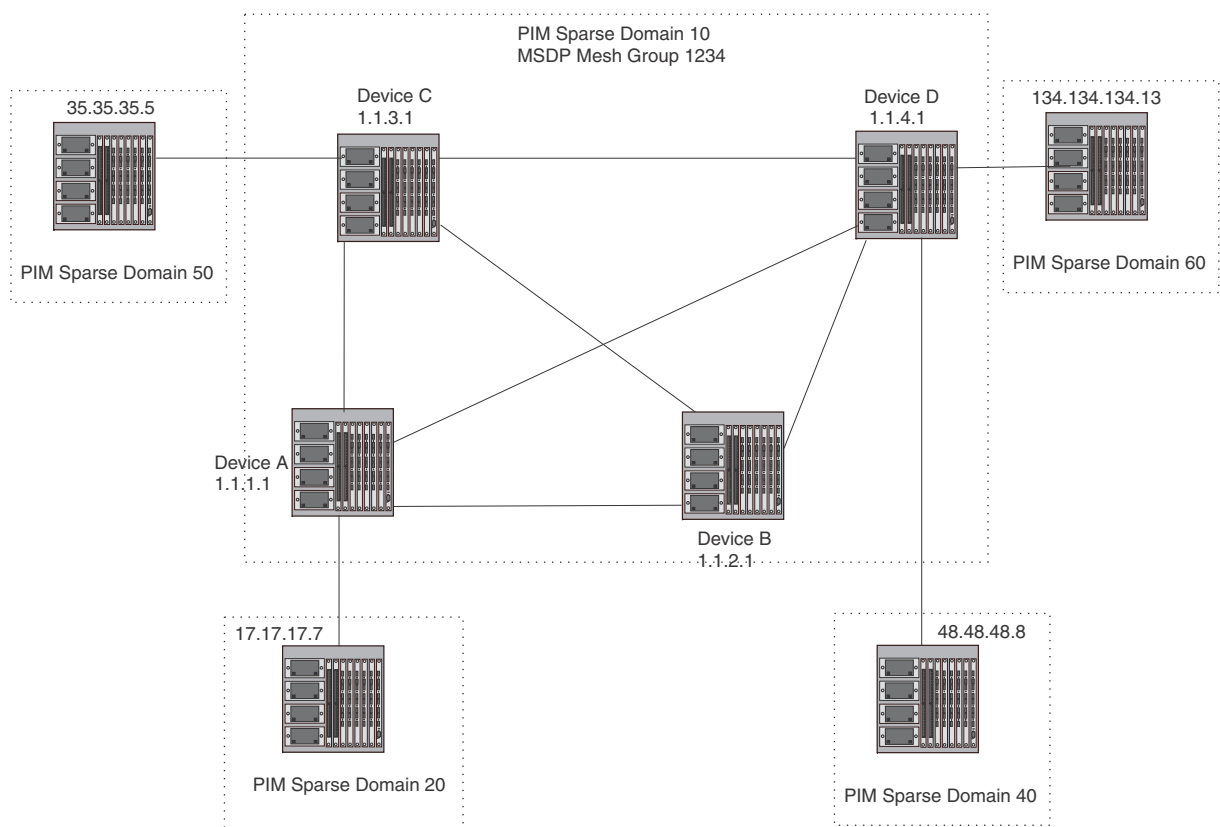

On each of the device that will be part of the mesh-group, there must be a mesh-group definition for all the peers in the mesh-group.

Up to 32 MSDP peers can be configured per mesh group.

Example configuration of an MSDP mesh group

In Figure 177, devices A, B, C, and D are in Mesh Group 1234. The example configuration following the figure shows how the devices are configured to be part of the MSDP mesh group. The example also shows the features that need to be enabled for the MSDP mesh group to work.

FIGURE 177 MSDP mesh group 1234

MSDP mesh group configuration for Device A

The following set of commands configure the MSDP peers of Device A (1.1.1.1) that are inside and outside MSDP mesh group 1234. Device A peers inside the mesh group 1234 are 1.1.2.1, 1.1.3.1, and 1.1.4.1. Device 17.17.17.7 is a peer of Device A, but is outside mesh group 1234. Multicast is enabled on Device A interfaces. PIM and BGP are also enabled.

```
Brocade(config)# router pim
```

```

Brocade(config)# router msdp
Brocade(config-msdp-router)# msdp-peer 1.1.3.1 connect-source loopback 1
Brocade(config-msdp-router)# msdp-peer 1.1.4.1 connect-source loopback 1
Brocade(config-msdp-router)# msdp-peer 1.1.2.1 connect-source loopback 1
Brocade(config-msdp-router)# msdp-peer 17.17.17.7
Brocade(config-msdp-router)# mesh-group 1234 1.1.4.1
Brocade(config-msdp-router)# mesh-group 1234 1.1.3.1
Brocade(config-msdp-router)# mesh-group 1234 1.1.2.1
Brocade(config-msdp-router)# exit

Brocade(config)# interface loopback 1
Brocade(config-lbif-1)# ip address 1.1.1.1 255.255.255.0

MSDP mesh group configuration for Device C

The following set of commands configure the MSDP peers of Device C (1.1.3.1) that are inside and outside MSDP mesh group 1234. Device C peers inside the mesh group 1234 are 1.1.1.1, 1.1.2.1, and 1.1.4.1. Device 35.35.35.5 is a peer of Device C, but is outside mesh group 1234. Multicast is enabled on Device C interfaces. PIM and BGP are also enabled.

```

Brocade(config)# router pim

Brocade(config)# router msdp
Brocade(config-msdp-router)# msdp-peer 35.35.35.5
Brocade(config-msdp-router)# msdp-peer 1.1.2.1 connect-source loopback 1
Brocade(config-msdp-router)# msdp-peer 1.1.4.1 connect-source loopback 1
Brocade(config-msdp-router)# msdp-peer 1.1.1.1 connect-source loopback 1
Brocade(config-msdp-router)# mesh-group 1234 1.1.2.1
Brocade(config-msdp-router)# mesh-group 1234 1.1.1.1
Brocade(config-msdp-router)# mesh-group 1234 1.1.4.1
Brocade(config-msdp-router)# exit

Brocade(config)# interface loopback 1
Brocade(config-lbif-1)# ip address 1.1.3.1 255.255.255.0
Brocade(config-lbif-1)# ip pim-sparse
Brocade(config-lbif-1)# exit

Brocade(config)# interface ethernet 3/1
Brocade(config-if-3/1)# ip address 32.32.32.3 255.255.255.0
Brocade(config-if-3/1)# ip pim-sparse
Brocade(config-if-3/1)# exit

Brocade(config)# interface ethernet 10/1
Brocade(config-if-10/1)# ip address 31.31.31.3 255.255.255.0

Brocade(config-router-bsr)# write memory

```

Displaying MSDP information

You can display the following MSDP information:

- Summary information – the IP addresses of the peers, the state of the Layer 3 switch MSDP session with each peer, and statistics for Keepalive, Source Active, and Notification messages sent to and received from each of the peers
- Peer information – the IP address of the peer, along with detailed MSDP and TCP statistics
- Source Active cache entries – the Source Active messages cached by the Layer 3 switch

Displaying summary information

To display summary MSDP information, enter the **show ip msdp summary** command at any level of the CLI:

```
Brocade(config-msdp-router)# show ip msdp summary
```

MSDP Peer Status Summary

KA: Keepalive SA:Source-Active NOT: Notification

Peer Address	State	KA		SA		NOT	
		In	Out	In	Out	In	Out
206.251.17.30	ESTABLISH	3	3	0	640	0	0
206.251.17.41	ESTABLISH	0	3	651	0	0	0

Syntax: show ip msdp summary

This display shows the following information.

TABLE 266 MSDP summary information

Field	Description
Peer Address	The IP address of the peer interface with the Layer 3 switch
State	The state of the MSDP router connection with the peer. The state can be one of the following: <ul style="list-style-type: none">• CONNECTING – The session is in the active open state.• ESTABLISHED – The MSDP session is fully up.• INACTIVE – The session is idle.• LISTENING – The session is in the passive open state.
KA In	The number of MSDP Keepalive messages the MSDP router has received from the peer
KA Out	The number of MSDP Keepalive messages the MSDP router has sent to the peer
SA In	The number of Source Active messages the MSDP router has received from the peer
SA Out	The number of Source Active messages the MSDP router has sent to the peer
NOT In	The number of Notification messages the MSDP router has received from the peer
NOT Out	The number of Notification messages the MSDP router has sent to the peer

Displaying peer information

To display summary MSDP peer information, enter the **show ip msdp peer** command.

```
Brocade(config-msdp-router)# show ip msdp peer
```

```

Total number of MSDP Peers: 2

1      IP Address      State

```

Syntax: show ip msdp peer

This display shows the following information.

TABLE 267 MSDP peer information

Field	Description
Total number of MSDP peers	The number of MSDP peers configured on the Layer 3 switch
IP Address	The IP address of the peer interface with the Layer 3 switch
State	The state of the MSDP router connection with the peer. The state can be one of the following: <ul style="list-style-type: none"> CONNECTING – The session is in the active open state. ESTABLISHED – The MSDP session is fully up. INACTIVE – The session is idle. LISTENING – The session is in the passive open state.
Keep Alive Time	The keep alive time, which specifies how often this MSDP router sends keep alive messages to the neighbor. The keep alive time is 60 seconds and is not configurable.
Hold Time	The hold time, which specifies how many seconds the MSDP router will wait for a KEEPALIVE or UPDATE message from an MSDP neighbor before deciding that the neighbor is dead. The hold time is 90 seconds and is not configurable.
Keep Alive Message Sent	The number of Keep Alive messages the MSDP router has sent to the peer.
Keep Alive Message Received	The number of Keep Alive messages the MSDP router has received from the peer.
Notifications Sent	The number of Notification messages the MSDP router has sent to the peer.

TABLE 267 MSDP peer information (Continued)

Field	Description
Notifications Received	The number of Notification messages the MSDP router has received from the peer.
Source-Active Sent	The number of Source Active messages the MSDP router has sent to the peer.
Source-Active Received	The number of Source Active messages the MSDP router has received from the peer.
Last Connection Reset Reason	The reason the previous session with this neighbor ended.
Notification Message Error Code Received	<p>If the MSDP router receives a NOTIFICATION messages from the neighbor, the message contains an error code corresponding to one of the following errors. Some errors have subcodes that clarify the reason for the error. Where applicable, the subcode messages are listed underneath the error code messages:</p> <ul style="list-style-type: none"> • 1 – Message Header Error • 2 – SA-Request Error • 3 – SA-Message/SA-Response Error • 4 – Hold Timer Expired • 5 – Finite State Machine Error • 6 – Notification • 7 – Cease <p>For information about these error codes, see section 17 in the Internet draft describing MSDP, “draft-ietf-msdp-spec”.</p>
Notification Message Error SubCode Received	See above.
Notification Message Error Code Transmitted	The error message corresponding to the error code in the NOTIFICATION message this MSDP router sent to the neighbor. See the description for the Notification Message Error Code Received field for a list of possible codes.
Notification Message Error SubCode Transmitted	See above.

TCP Statistics

TABLE 267 MSDP peer information (Continued)

Field	Description
TCP connection state	<p>The state of the connection with the neighbor. The connection can have one of the following states:</p> <ul style="list-style-type: none"> • LISTEN – Waiting for a connection request. • SYN-SENT – Waiting for a matching connection request after having sent a connection request. • SYN-RECEIVED – Waiting for a confirming connection request acknowledgment after having both received and sent a connection request. • ESTABLISHED – Data can be sent and received over the connection. This is the normal operational state of the connection. • FIN-WAIT-1 – Waiting for a connection termination request from the remote TCP, or an acknowledgment of the connection termination request previously sent. • FIN-WAIT-2 – Waiting for a connection termination request from the remote TCP. • CLOSE-WAIT – Waiting for a connection termination request from the local user. • CLOSING – Waiting for a connection termination request acknowledgment from the remote TCP. • LAST-ACK – Waiting for an acknowledgment of the connection termination request previously sent to the remote TCP (which includes an acknowledgment of its connection termination request). • TIME-WAIT – Waiting for enough time to pass to be sure the remote TCP received the acknowledgment of its connection termination request. • CLOSED – There is no connection state.
Local host	The IP address of the MSDP router interface with the peer.
Local port	The TCP port the MSDP router is using for the BGP4 TCP session with the neighbor.
Remote host	The IP address of the neighbor.
Remote port	The TCP port number of the peer end of the connection.
ISentSeq	The initial send sequence number for the session.
SendNext	The next sequence number to be sent.
TotUnAck	The number of sequence numbers sent by the MSDP router that have not been acknowledged by the neighbor.
SendWnd	The size of the send window.
TotSent	The number of sequence numbers sent to the neighbor.
ReTrans	The number of sequence numbers that the MSDP router retransmitted because they were not acknowledged.
IRcvSeq	The initial receive sequence number for the session.
RcvNext	The next sequence number expected from the neighbor.
RcvWnd	The size of the receive window.
TotalRcv	The number of sequence numbers received from the neighbor.
RcvQue	The number of sequence numbers in the receive queue.
SendQue	The number of sequence numbers in the send queue.

Displaying source active cache information

To display the Source Actives in the MSDP cache, enter the **show ip msdp sa-cache** command.

```
Brocade(config-msdp-router)# show ip msdp sa-cache
```

```
Total Entry 4096, Used 1800 Free 2296
Index   SourceAddr  GroupAddr          Age
1      (100.100.1.254, 232.1.0.95), RP:206.251.17.41, Age:0
2      (100.100.1.254, 237.1.0.98), RP:206.251.17.41, Age:30
3      (100.100.1.254, 234.1.0.48), RP:206.251.17.41, Age:30
4      (100.100.1.254, 239.1.0.51), RP:206.251.17.41, Age:30
5      (100.100.1.254, 234.1.0.154), RP:206.251.17.41, Age:30
6      (100.100.1.254, 236.1.0.1), RP:206.251.17.41, Age:30
7      (100.100.1.254, 231.1.0.104), RP:206.251.17.41, Age:90
8      (100.100.1.254, 239.1.0.157), RP:206.251.17.41, Age:30
9      (100.100.1.254, 236.1.0.107), RP:206.251.17.41, Age:30
10     (100.100.1.254, 233.1.0.57), RP:206.251.17.41, Age:90
```

Syntax: **show ip msdp sa-cache**

This display shows the following information.

TABLE 268 MSDP source active cache

Field	Description
Total Entry	The total number of entries the cache can hold.
Used	The number of entries the cache currently contains.
Free	The number of additional entries for which the cache has room.
Index	The cache entry number.
SourceAddr	The IP address of the multicast source.
GroupAddr	The IP multicast group to which the source is sending information.
RP	The RP through which receivers can access the group traffic from the source
Age	The number of seconds the entry has been in the cache

Clearing MSDP information

You can clear the following MSDP information:

- Peer information
- Source Active cache
- MSDP statistics

Clearing peer information

To clear MSDP peer information, enter the **clear ip msdp peer** command at the Privileged EXEC level of the CLI:

```
Brocade# clear ip msdp peer 205.216.162.1
Remote connection closed
```

Syntax: **clear ip msdp peer** <ip-addr>

The command in this example clears the MSDP peer connection with MSDP router 205.216.162.1. The CLI displays a message to indicate when the connection has been successfully closed.

Clearing the source active cache

To clear the entries from the Source Active cache, enter the **clear ip msdp sa-cache** command at the Privileged EXEC level of the CLI:

```
Brocade# clear ip msdp sa-cache
```

Syntax: **clear ip msdp sa-cache** [*<source-addr>* | *<group-addr>*]

The command in this example clears all the cache entries. Use the *<source-addr>* parameter to clear only the entries for a specified source. Use the *<group-addr>* parameter to clear only the entries for a specific group.

Clearing MSDP statistics

To clear MSDP statistics, enter the **clear ip msdp statistics** command at the Privileged EXEC level of the CLI:

```
Brocade# clear ip msdp statistics
```

Syntax: **clear ip msdp statistics** [*<ip-addr>*]

The command in this example clears statistics for all the peers. To clear statistics for a specific peer, enter the peer IP address.

Passive multicast route insertion

Passive Multicast Route Insertion (PMRI) enables a Layer 3 switch running PIM Sparse to create an entry for a multicast route (e.g., (S,G)), with no directly attached clients or when connected to another PIM router (transit network).

PMRI is critical for Service Providers wanting to deliver IP-TV services or multicast-based video services. Service Providers, who have transit networks, distribute multicast-based video services to other Service Providers, regardless of whether a client subscribes to a video service.

PMRI is enabled by default. To disable it, enter the following commands at the **router pim** level of the CLI.

```
Brocade(config)#router pim
Brocade#(config-pim-router)#no hardware-drop
```

Syntax: **[no] hardware-drop**

When PMRI is enabled, the **show ip pim mcache** command output displays the multicast cache entry along with a drop flag, indicating that the device is dropping packets in hardware. If the HW flag is set to 1 (HW=1), it implies that the packets are being dropped in hardware. If the HW flag is set to 0, (HW=0), it indicates that the packets are being processed in software. The following shows an example display output.

```

Brocade#show ip pim mcache
1 (10.10.10.18 226.0.1.56) in v10 (e1), cnt=2
Source is directly connected
Sparse Mode, RPT=0 SPT=1 REG=1 MSDP Adv=0 MSDP Create=0
fast=0 slow=0 pru=1 graft age drop
age=0s up-time=2m HW=1 L2-vidx=8191

```

DVMRP overview

Brocade routers provide multicast routing with the Distance Vector Multicast Routing Protocol (DVMRP) routing protocol. DVMRP uses Internet Group Membership Protocol (IGMP) to manage the IP multicast groups.

DVMRP is a broadcast and pruning multicast protocol that delivers IP multicast datagrams to its intended receivers. The receiver registers the interested groups using IGMP. DVMRP builds a multicast delivery tree with the sender forming the root. Initially, multicast datagrams are delivered to all nodes on the tree. Those leaves that do not have any group members send **prune messages** to the upstream router, noting the absence of a group. The upstream router maintains a prune state for this group for the given sender. A prune state is aged out after a given configurable interval, allowing multicasts to resume.

DVMRP employs **reverse path forwarding** and **pruning** to keep source specific multicast delivery trees with the minimum number of branches required to reach all group members. DVMRP builds a multicast tree for each source and destination host group.

NOTE

DVMRP is supported only on FastIron SX devices.

Initiating DVMRP multicasts on a network

Once DVMRP is enabled on each router, a network user can begin a video conference multicast from the server on R1. **Multicast Delivery Trees** are initially formed by source-originated multicast packets that are propagated to downstream interfaces as seen in [Figure 178](#). When a multicast packet is received on a DVMRP-capable router interface, the interface checks its DVMRP routing table to determine whether the interface that received the message provides the shortest path back to the source. If the interface does provide the shortest path, the interface forwards the multicast packet to adjacent peer DVMRP routers, except for the router interface that originated the packet. Otherwise, the interface discards the multicast packet and sends a prune message back upstream. This process is known as reverse path forwarding.

In [Figure 178](#), the root node (R1) is forwarding multicast packets for group 229.225.0.2 that it receives from the server to its downstream nodes, R2, R3, and R4. Router R4 is an intermediate router with R5 and R6 as its downstream routers. Because R5 and R6 have no downstream interfaces, they are leaf nodes.

The receivers in this example are those workstations that are resident on routers R2, R3, and R6.

Pruning a multicast tree

After the multicast tree is constructed, **pruning** of the tree will occur after IP multicast packets begin to traverse the tree.

As multicast packets reach leaf networks (subnets with no downstream interfaces), the local IGMP database checks for the recently arrived IP multicast packet address. If the local database does not contain the address (the address has not been learned), the router prunes (removes) the address from the multicast tree and no longer receives multicasts until the prune age expires.

In [Figure 178](#), Router 5 is a leaf node with no group members in its local database. Consequently, Router 5 sends a prune message to its upstream router. This router will not receive any further multicast traffic until the prune age interval expires.

FIGURE 178 Downstream broadcast of IP multicast packets from source host

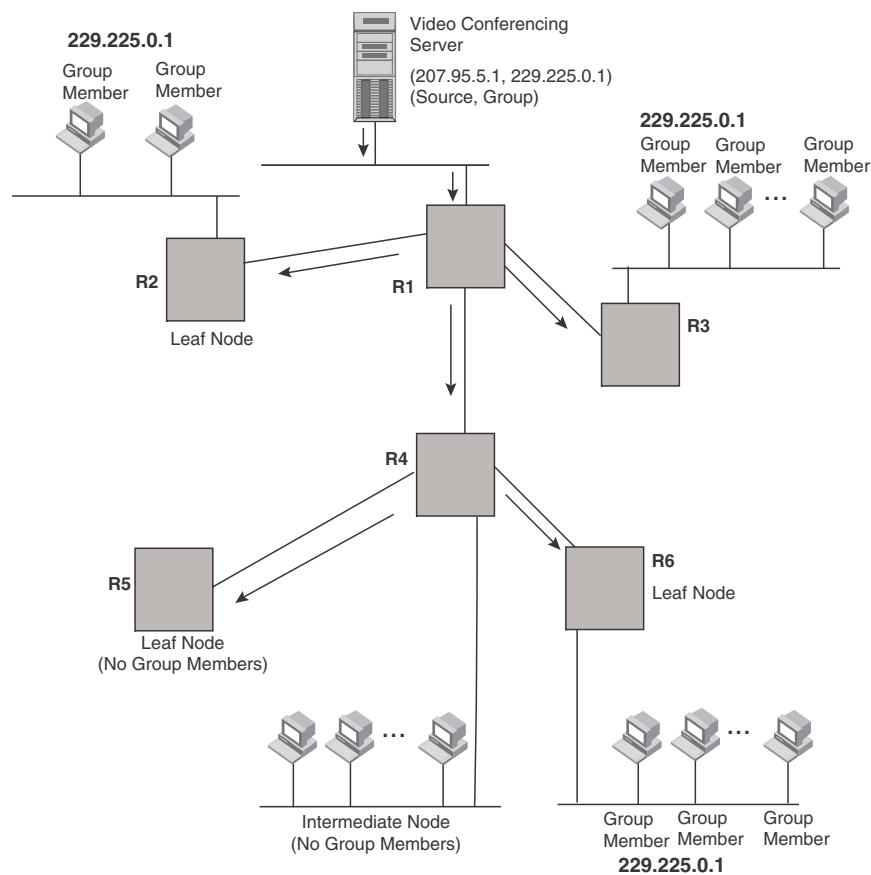

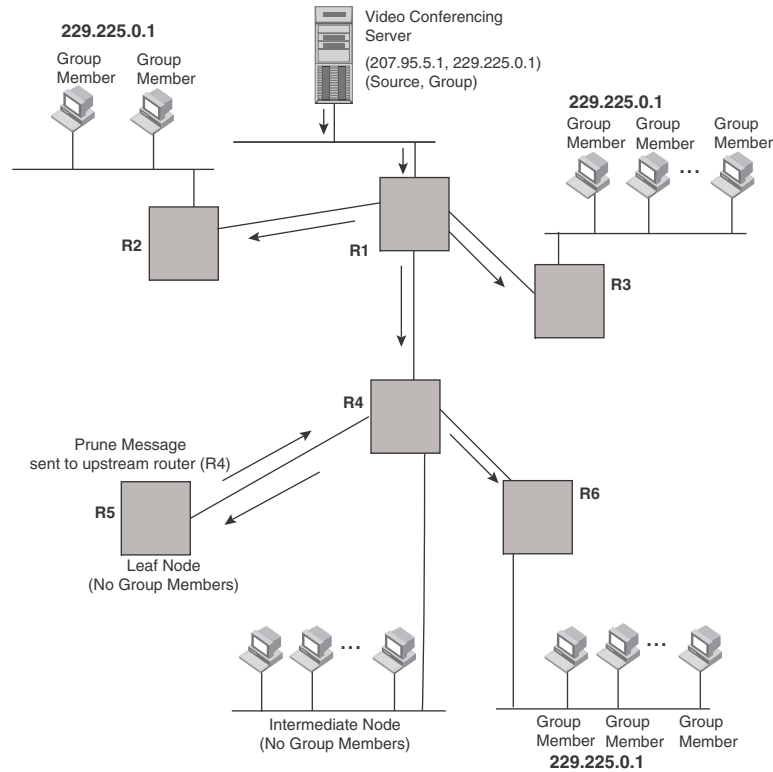

FIGURE 179 Pruning leaf nodes from a multicast tree

Grafts to a multicast tree

A DVMRP router restores pruned branches to a multicast tree by sending graft messages towards the upstream switch. Graft messages start at the leaf node and travel up the tree, first sending the message to its neighbor upstream switch.

In the example above, if a new 229.255.0.1 group member joins on switch S6, which had been pruned previously, a graft will be sent upstream to S4. Since the forwarding state for this entry is in a prune state, S4 sends a graft to S1. Once S4 has joined the tree, it and S6 will once again receive multicast packets.

You do not need to perform any configuration to maintain the multicast delivery tree. The prune and graft messages automatically maintain the tree.

DVMRP configuration on the Layer 3 switch and interface

Suppose you want to initiate the use of desktop video for fellow users on a sprawling campus network. All destination workstations have the appropriate hardware and software but the Layer 3 switches that connect the various buildings need to be configured to support Distance Vector Multicast Protocol (DVMRP) multicasts from the designated video conference server as seen in [Figure 178](#).

DVMRP is enabled on each of the Brocade Layer 3 switches shown in [Figure 178](#), on which multicasts are expected. You can enable DVMRP on each Layer 3 switch independently or remotely from one Layer 3 switch by a Telnet connection. Follow the same steps for each Layer 3 switch.

Globally enabling and disabling DVMRP

To globally enable DVMRP, enter the **router dvmrp** command.

```
Router1(config)#router dvmrp
```

Syntax: [no] router dvmrp

The behavior of the [no] **router dvmrp** command is as follows:

- Entering a **router dvmrp** command to enable DVMRP does not require a software reload.
- Entering a **no router dvmrp** command removes all configuration for PIM multicast on a Layer 3 switch (**router pim** level) only.

Globally enabling or disabling DVMRP without deleting multicast configuration

As stated above enter **no router dvmrp** removed PIM configuration. If you want to disable or enable DVMRP without removing PIM configuration, enter the following commands.

```
Brocade(config)#router dvmrp
Brocade(config-pim-router)#disable-dvmrp
```

Syntax: [no] disable-dvmrp

Use the [no] version of the command to re-enable DVMRP.

Enabling DVMRP on an interface

After globally enabling DVMRP on a Layer 3 switch, enable it on each interface that will support the protocol.

To enable DVMRP on S1 and interface 3, enter the following commands.

```
Router1(config)#router dvmrp
Router1(config-dvmrp-router)#int e 3
Router1(config-if-3)#ip dvmrp
```

Modifying DVMRP global parameters

DVMRP global parameters come with preset values. The defaults work well in most networks, but you can modify the following global parameters if you need to:

- Neighbor timeout
- Route expire time
- Route discard time
- Prune age
- Graft retransmit time
- Probe interval
- Report interval
- Trigger interval

- Default route

Modifying neighbor timeout

The neighbor timeout specifies the period of time that a router will wait before it defines an attached DVMRP neighbor router as down. Possible values are 40 – 8000 seconds. The default value is 180 seconds.

To modify the neighbor timeout value to 100, enter the **nbr <num>** command.

```
Brocade(config-dvmrp-router)#nbr 100
```

Syntax: **nbr-timeout <40-8000>**

The default is 180 seconds.

Modifying Route Expires Time

The Route Expire Time defines how long a route is considered valid in the absence of the next route update. Possible values are from 20 – 4000 seconds. The default value is 200 seconds.

To modify the route expire setting to 50, enter the **route-expire-timeout <num>** command.

```
Brocade(config-dvmrp-router)#route-expire-timeout 50
```

Syntax: **route-expire-timeout <20-4000>**

Modifying Route Discard Time

The Route Discard Time defines the period of time before a route is deleted. Possible values are from 40 – 8000 seconds. The default value is 340 seconds.

To modify the route discard setting to 150, enter the **route-discard-timeout <num>** command.

```
Brocade(config-dvmrp-router)#route-discard-timeout 150
```

Syntax: **route-discard-timeout <40-8000>**

Modifying Prune Age

The Prune Age defines how long a prune state will remain in effect for a source-routed multicast tree. After the prune age period expires, flooding will resume. Possible values are from 20 – 3600 seconds. The default value is 180 seconds.

To modify the prune age setting to 150, enter the **prune <num>** command.

```
Brocade(config-dvmrp-router)#prune 25
```

Syntax: **prune-age <20-3600>**

Modifying Graft Retransmit Time

The Graft Retransmit Time defines the initial period of time that a router sending a graft message will wait for a graft acknowledgement from an upstream router before re-transmitting that message.

Subsequent retransmissions are sent at an interval twice that of the preceding interval. Possible values are from

5 – 3600 seconds. The default value is 10 seconds.

To modify the setting for graft retransmit time to 120, enter the **graft <num>** command.

```
Brocade(config-dvmrp-router)#graft 120
```

Syntax: **graft-retransmit-time** <5-3600>

Modifying Probe Interval

The Probe Interval defines how often neighbor probe messages are sent to the ALL-DVMRP-ROUTERS IP multicast group address. A router probe message lists those neighbor DVMRP routers from which it has received probes. Possible values are from 5 – 30 seconds. The default value is 10 seconds.

To modify the probe interval setting to 10, enter the **probe <num>** command.

```
Brocade(config-dvmrp-router)#probe 10
```

Syntax: **probe-interval** <5-30>

Modifying Report Interval

The Report Interval defines how often routers propagate their complete routing tables to other neighbor DVMRP routers. Possible values are from 10 – 2000 seconds. The default value is 60 seconds.

To support propagation of DVMRP routing information to the network every 90 seconds, enter the **report <num>** command.

```
Brocade(config-dvmrp-router)#report 90
```

Syntax: **report-interval** <10-2000>

Modifying Trigger Interval

The Trigger Interval defines how often trigger updates, which reflect changes in the network topology, are sent. Example changes in a network topology include router up or down or changes in the metric. Possible values are from 5 – 30 seconds. The default value is 5 seconds.

To support the sending of trigger updates every 20 seconds, enter the **trigger-interval <num>** command.

```
Brocade(config-dvmrp-router)#trigger-interval 20
```

Syntax: **trigger-interval** <5-30>

Modifying default route

To define the default gateway for DVMRP, enter the following command.

```
Brocade(config-dvmrp-router)#default-gateway 192.35.4.1
```

Syntax: **default-gateway** <ip-addr>

Modifying DVMRP interface parameters

DVMRP global parameters come with preset values. The defaults work well in most networks, but you can modify the following interface parameters if you need to:

- TTL
- Metric
- Advertising

Modifying the TTL

The time to live (TTL) value defines the minimum value required in a packet in order for the packet to be forwarded out the interface. For example, if the TTL for an interface is set at 10 it means that only those packets with a TTL value of 10 or more are forwarded. Likewise, if an interface is configured with a TTL Threshold value of 1, all packets received on that interface are forwarded. Possible values are from 1 – 64. The default value is 1.

To set a TTL of 64, enter the following commands.

```
Brocade(config)#int e 1/4  
Brocade(config-if-1/4)#ip dvmrp ttl 60
```

Syntax: ttl-threshold <1-64>

Modifying the metric

The router uses the metric when establishing reverse paths to some networks on directly attached interfaces. Possible values are from 1 – 31 hops. The default is 1.

NOTE

This command is not supported on Brocade Layer 2 Switches.

To set a metric of 15 for a DVMRP interface, enter the following commands.

```
Brocade(config)#interface 3/5  
Brocade(config-if-3/5)#ip dvmrp metric 15
```

Syntax: ip dvmrp metric <1-31>

Enabling advertising

You can turn the advertisement of a local route on (enable) or off (disable) on the interface. By default, advertising is enabled.

To enable advertising on an interface, enter the following commands.

```
Brocade(config-if-1/4)#ip dvmrp advertise-local on
```

Syntax: advertise-local on | off

Displaying information about an upstream neighbor device

You can view information about the upstream neighbor device for a given source IP address for IP PIM packets. The software uses the IP route table or multicast route table to lookup the upstream neighbor device.

The following shows example messages that the Brocade device can display with this command.

```
Brocade#show ip dvmrp rpf 1.1.20.2
directly connected or through an L2 neighbor
Brocade#show ip dvmrp rpf 1.2.3.4
no route
Brocade#show ip dvmrp rpf 1.10.10.24
upstream neighbor=1.1.20.1 on v21 using ip route
```

Syntax: `show ip dvmrp rpf <IP address>`

where `<IP address>` is a valid source IP address

NOTE

If there are multiple equal cost paths to the source, the `show ip dvmrp rpf` command output may not be accurate. If your system has multiple equal cost paths, use the command `show ip dvmrp mcache` to view information about the upstream neighbor.

```
Brocade(config)#router dvmrp
Brocade(config-pim-router)#disable-dvmrp
```

Syntax: `[no] disable-dvmrp`

Use the `[no]` version of the command to re-enable DVMRP.

Enabling DVMRP on an interface

After globally enabling DVMRP on a Layer 3 switch, enable it on each interface that will support the protocol.

To enable DVMRP on S1 and interface 3, enter the following.

```
Router1(config)#router dvmrp
Router1(config-dvmrp-router)#int e 3
Router1(config-if-3)#ip dvmrp
```

IP tunnel configuration

IP tunnels are used to send traffic through routers that do not support IP multicasting. IP Multicast datagrams are encapsulated within an IP packet and then sent to the remote address. Routers that are not configured for IP Multicast route the packet as a normal IP packet. When the IP Multicast router at the remote end of the tunnel receives the packet, the router strips off the IP encapsulation and forwards the packet as an IP Multicast packet.

NOTE

An IP tunnel must have a remote IP interface at each end. Also, for IP tunneling to work, the remote routers must be reachable by an IP routing protocol.

NOTE

Multiple tunnels configured on a router cannot share the same remote address.

Example

To configure an IP tunnel as seen in [Figure 178](#), enter the IP tunnel destination address on an interface of the router.

To configure an IP address on Router A, enter the following commands.

```
FastIron(config)#int e1
FastIron(config-if-1)#ip tunnel 192.3.45.6
```

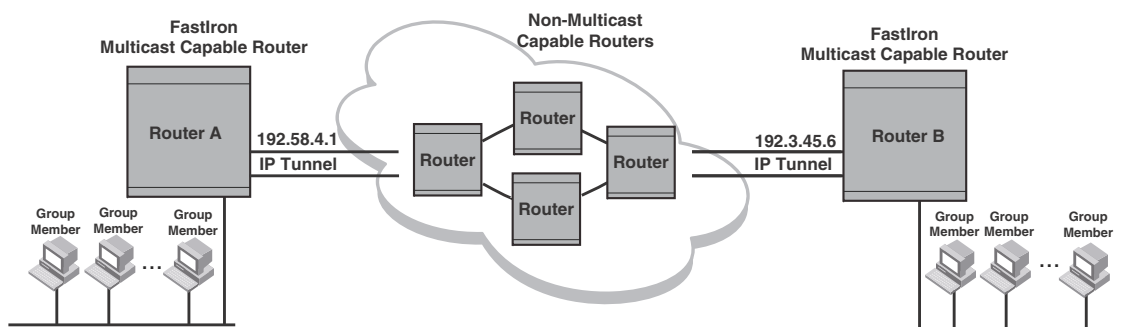

NOTE

The IP tunnel address represents the configured IP tunnel address of the destination router. In the case of Router A, its destination router is Router B. Router A is the destination router of Router B.

For router B, enter the following.

```
FastIron(config-if-1)#ip tunnel 192.58.4.1
```

FIGURE 180 IP in IP tunneling on multicast packets in a unicast network

Using ACLs to control multicast features

You can use ACLs to control the following multicast features:

- Limit the number of multicast groups that are covered by a static rendezvous point (RP)
- Control which multicast groups for which candidate RPs sends advertisement messages to bootstrap routers
- Identify which multicast group packets will be forwarded or blocked on an interface

Using ACLs to limit static RP groups

You can limit the number of multicast groups covered by a static RP using standard ACLs. In the ACL, you specify the group to which the RP address applies. The following examples set the RP address to be applied to multicast groups with some minor variations.

To configure an RP that covers multicast groups in 239.255.162.x, enter commands such as the following.

```
Brocade(config)#access-list 2 permit 239.255.162.0 0.0.0.255
Brocade(config)#router pim
Brocade(config-pim-router)#rp-address 43.43.43.1 2
```

To configure an RP that covers multicast groups in the 239.255.162.x range, except the 239.255.162.2 group, enter commands such as the following.

```
Brocade(config)#access-list 5 deny host 239.255.162.2
Brocade(config)#access-list 5 permit 239.255.0.0 0.0.255.255
Brocade(config)#router pim
Brocade(config-pim-router)#bsr-candidate ve 43 32 100
Brocade(config-pim-router)#rp-candidate ve 43
Brocade(config-pim-router)#rp-address 99.99.99.5 5
```

To configure an RP for multicast groups using the override switch, enter commands such as the following.

```
Brocade(config)#access-list 44 permit 239.255.162.0 0.0.0.255
Brocade(config)#router pim
Brocade(config-pim-router)#rp-address 43.43.43.1
Brocade(config-pim-router)#rp-address 99.99.99.5 44 override
```

Syntax: [no] **rp-address** <ip-address> [<access-list-num>] [**override**]

The access-list-num parameter is the number of the standard ACL that will filter the multicast group.

NOTE

Extended ACLs cannot be used to limit static RP groups.

The **override** parameter directs the Layer 3 switch to ignore the information learned by a BSR if there is a conflict between the RP configured in this command and the information that is learned by the BSR. An RP address learned dynamically from PIM Bootstrap protocol takes precedence over static RP configuration unless the override parameter is used.

You can use the **show ip pim rp-set** command to display the ACLs used to filter the static RP groups.

Example

```
Brocade#show ip pim rp-set
Group address      Static-RP-address  Override
-----
Access-List 44    99.99.99.5         On
Number of group prefixes Learnt from BSR: 1
Group prefix = 224.0.0.0/4 #RPs: 1
RP 1: 43.43.43.1 priority=0 age=0
```

In the example above, the display shows the following information:

- The Group Address table shows the static RP address that is covered by the access list, and whether or not the override parameter has been enabled.
- The Group prefix line shows the multicast group prefix for the static RP.
- The RP #line shows the configured IP address of the RP candidate.

Enter the **show ip pim rp-map** command to display the group-to-RP mapping.

```
router(config)# show ip pim rp-map
Number of group-to-RP mappings: 5
Group address RP address
-----
1  230.0.0.1 100.1.1.1
2  230.0.0.2 100.1.1.1
3  230.0.0.3 100.1.1.1
4  230.0.0.4 100.1.1.1
5  230.0.0.5 100.1.1.1
```

The display shows the multicast group addresses covered by the RP candidate and the IP address of the RP for the listed multicast group. In the example above, you see the following:

- The first three lines show the multicast group addresses that are covered by the RP candidate.
- The last three lines show the multicast group addresses covered by the static RP.

Using ACLs to limit PIM RP candidate advertisement

You can use standard ACLs to control the groups for which the candidate RP will send advertisement messages to the bootstrap router. For example, ACL 5 can be configured to be applied to the multicast groups within the IP address 239.x.x.x range. You can configure the Layer 3 switch to advertise itself as a candidate RP to the bootstrap router only for groups in the range of 239.x.x.x. Enter commands such as the following.

```
Brocade(config)#interface ethernet 1/1
Brocade(config-if-1/1)#ip address 99.99.99.5 255.255.255.0
Brocade(config-if-1/1)#ip pim-sparse
Brocade(config-if-1/1)#exit
Brocade(config)#access-list 5 deny host 239.255.162.2
Brocade(config)#access-list 5 permit 239.0.0.0 0.0.255.255
Brocade(config)#router pim
Brocade(config-pim-router)#bsr-candidate ethernet 1/1 32 100
Brocade(config-pim-router)#rp-candidate ethernet 1/1 group-list 5
```

The example above shows a configuration for an Ethernet interface. To configure ACLs that are applied to a virtual routing interface, enter commands such as the following.

```
Brocade(config)#interface ve 16
Brocade(config-vif-16)#ip address 16.16.16.1 255.255.255.0
Brocade(config-vif-16)#ip pim-sparse
Brocade(config-vif-16)#exit
Brocade(config)#access-list 5 deny host 239.255.162.2
Brocade(config)#access-list 5 permit 239.255.0.0 0.0.255.255
Brocade(config)#router pim
Brocade(config-pim-router)#bsr-candidate ve 16 32 100
Brocade(config-pim-router)#rp-candidate ve 16 group-list 5
```

To configure ACLs that are applied to a loopback interface, enter commands such as the following.

```
Brocade(config)#interface loopback 1
Brocade(config-lbif-1)#ip address 88.88.88.8 255.255.255.0
Brocade(config-lbif-1)#ip pim-sparse
Brocade(config-lbif-1)#exit
```

```

Brocade(config)#access-list 5 deny host 239.255.162.2
Brocade(config)#access-list 5 permit 239.255.0.0 0.0.255.255
Brocade(config)#router pim
Brocade(config-pim-router)#bsr-candidate loopback 1 32 100
Brocade(config-pim-router)#rp-candidate loopback 1 group-list 5

```

Syntax: [no] **rp-candidate ethernet** [<slotnum> / <portnum> | **loopback** <num> | **ve** <num>]
[group-list <access-list-num>]

The <slotnum> parameter is required on chassis devices.

The <portnum> | **loopback** <num> | **ve** <num> parameter specifies the interface. The Layer 3 switch will advertise the specified interface IP address as a candidate RP:

- Enter **ethernet** [<slotnum> / <portnum>] for a physical interface (port).
- Enter **ve** <num> for a virtual interface.
- Enter **loopback** <num> for a loopback interface.

The **group-list** <access-list-num> indicates that a standard ACL is used to filter for which multicast group the advertisement will be made.

NOTE

Extended ACLs cannot be used for group-list.

Disabling CPU processing for select multicast groups

In IPv4 multicast, Brocade Layer 3 switches do not forward multicast packets with destination addresses in the range between 224.0.0.0 and 224.0.0.255. These group addresses are reserved for various routing protocols. By default, packets destined to these groups are processed by the CPU. However, when a large number of packets for these groups are received by the Brocade device all at once, CPU resources may be overloaded. To alleviate the load on the CPU, you could disable CPU processing of packets for these groups. When applied, this feature protects the CPU from traffic sent to IPV4 multicast addresses in the range 224.0.0.1 - 224.0.0.254, and instead floods these packets in hardware within the incoming VLAN.

This feature can be applied on a VLAN or a VLAN-group. If applied on a VLAN, traffic received on a port of the VLAN will be flooded to all other ports of the VLAN. If applied on a VLAN-group, traffic will be flooded only at the individual VLAN level. Once this feature is applied on a VLAN or VLAN-group, ports that are statically or dynamically added to the VLAN or VLAN-group will inherit the configuration. Likewise, ports that are statically or dynamically removed from the VLAN or VLAN-group will drop the configuration.

This feature can be enabled for packets destined to a multicast group or set of groups in the range 224.0.0.1 – 224.0.0.254, except for the reserved multicast addresses listed in the following table.

TABLE 269 Reserved multicast addresses

Multicast address	Reserved for...
224.0.0.1	all nodes
224.0.0.2	PIM
224.0.0.3	DVMRP
224.0.0.4	DVMRP
224.0.0.5	OSPF

TABLE 269 Reserved multicast addresses (Continued)

Multicast address	Reserved for...
224.0.0.6	OSPF
224.0.0.9	RIP V2
224.0.0.13	PIM V2
224.0.0.18	VRRP
224.0.0.22	IGMP V3 reports

CLI command syntax to disable CPU processing

To disable CPU processing for selective multicast groups, enter commands such as the following.

```
Brocade# config t
Brocade(config)# vlan 5
Brocade(config-vlan-5)# disable multicast-to-cpu 224.0.0.5
Brocade(config-vlan-5)# disable multicast-to-cpu 224.0.0.14 224.0.0.230
Brocade(config-vlan-5)# vlan 10
Brocade(config-vlan-10)# disable multicast-to-cpu 224.0.0.23
Brocade(config-vlan-10)# vlan 20
Brocade(config-vlan-20)# disable multicast-to-cpu 224.0.0.50 224.0.0.140
```

Syntax: [no] **disable multicast-to-cpu** <multicast group address> [<multicast group range end address>]

The <multicast group address> must be in the range 224.0.0.1 - 224.0.0.254, but cannot be one of the reserved multicast addresses listed in [Table 269](#) on page 1591.

Viewing disabled multicast addresses

To display disabled multicast addresses for all configured VLANs, enter the **show disabled-multicast-to-cpu** command. The following shows an example display.

```
Brocade# show disabled-multicast-to-cpu

Disabled multicast addresses to cpu for PORT-VLAN 5 :
  224.0.0.5
  224.0.0.14 to 224.0.0.230

Disabled multicast addresses to cpu for PORT-VLAN 10 :
  224.0.0.23

Disabled multicast addresses to cpu for PORT-VLAN 20 :
  224.0.0.50 to 224.0.0.140
```

To display disabled multicast addresses for a particular VLAN, include the VLAN ID with the **show disabled-multicast-to-cpu** command. The following shows an example display.

```
Brocade# show disabled-multicast-to-cpu 5
Disabled multicast addresses to cpu for PORT-VLAN 5 :
  224.0.0.5
  224.0.0.14 to 224.0.0.230
```

Syntax: `show disabled-multicast-to-cpu [<vlan-id>]`

For <vlan-id>, enter a valid VLAN ID. Note that each VLAN must have at least one port added to it.

Configuring a static multicast route

Static multicast routes allow you to control the network path used by multicast traffic. Static multicast routes are especially useful when the unicast and multicast topologies of a network are different. You can avoid the need to make the topologies similar by instead configuring static multicast routes.

NOTE

This feature is not supported for DVMRP.

You can configure more than one static multicast route. The Layer 3 switch always uses the most specific route that matches a multicast source address. Thus, if you want to configure a multicast static route for a specific multicast source and also configure another multicast static route for all other sources, you can configure two static routes as shown in the examples below.

To add static routes to multicast router A (refer to [Figure 181](#)), enter commands such as the following.

```
PIMRouterA(config)#ip mroute 1 207.95.10.0 255.255.255.0 interface ethernet 1/2
distance 1
PIMRouterA(config)#ip mroute 2 0.0.0.0 0.0.0.0 interface ethernet 2/3 distance 1
PIMRouterA(config)#write memory
```

Syntax: `mroute <route-num> <ip-addr> interface ethernet [<slotnum>/]<portnum> | ve <num> [distance <num>]`

or

Syntax: `mroute <route-num> <ip-addr> rpf_address <rpf-num>`

The <route-num> parameter specifies the route number.

The <ip-addr> command specifies the PIM source for the route.

NOTE

In IP multicasting, a route is handled in terms of its source, rather than its destination.

You can use the **ethernet** [<slotnum>/]<portnum> parameter to specify a physical port or the **ve** <num> parameter to specify a virtual interface.

NOTE

The **ethernet** [<slotnum>/]<portnum> parameter does not apply to PIM SM.

The **distance** <num> parameter sets the administrative distance for the route. When comparing multiple paths for a route, the Layer 3 switch prefers the path with the lower administrative distance.

NOTE

Regardless of the administrative distances, the Layer 3 switch always prefers directly connected routes over other routes.

The **rpf_address** <rpf-num> parameter specifies an RPF number.

Configuring a static multicast route

The example above configures two static multicast routes. The first route is for a specific source network, 207.95.10.0/24. If the Layer 3 switch receives multicast traffic for network 207.95.10.0/24, the traffic must arrive on port 1/2. The second route is for all other multicast traffic. Traffic from multicast sources other than 207.95.10.0/24 must arrive on port 2/3.

Figure 181 shows an example of an IP Multicast network. The two static routes configured in the example above apply to this network. The commands in the example above configure PIM router A to accept PIM packets from 207.95.10.0/24 when they use the path that arrives at port 1/2, and accept all other PIM packets only when they use the path that arrives at port 2/3.

The distance parameter sets the administrative distance. This parameter is used by the software to determine the best path for the route. Thus, to ensure that the Layer 3 switch uses the default static route, assign a low administrative distance value. When comparing multiple paths for a route, the Layer 3 switch prefers the path with the lower administrative distance.

FIGURE 181 Example of multicast static routes

To add a static route to a virtual interface, enter commands such as the following.

```
Brocade(config)# ip mroute 3 0.0.0.0 0.0.0.0 int ve 1 distance 1
Brocade(config)# write memory
```

Displaying the multicast configuration for another multicast router

The Brocade implementation of Mrinfo is based on the DVMRP Internet draft by T. Pusateri, but applies to PIM and not to DVMRP. To display the PIM configuration of another PIM router, use the following commands.

NOTE

This feature is not supported for DVMRP.

To display another PIM router PIM configuration, enter a command such as the following.

```
Brocade#mrinfo 207.95.8.1
207.95.8.1 -> 207.95.8.10 [PIM/0 /1]
207.95.10.2 -> 0.0.0.0 [PIM/0 /1 /leaf]
209.157.25.1 -> 0.0.0.0 [PIM/0 /1 /leaf]
209.157.24.1 -> 0.0.0.0 [PIM/0 /1 /leaf]
207.95.6.1 -> 0.0.0.0 [PIM/0 /1 /leaf]
128.2.0.1 -> 0.0.0.0 [PIM/0 /1 /leaf]
```

Syntax: `mrinfo <ip-addr>`

The `<ip-addr>` parameter specifies the IP address of the PIM router.

The output in this example is based on the PIM group shown in [Figure 174](#) on page 1532. The output shows the PIM interfaces configured on PIM router C (207.95.8.1). In this example, the PIM router has six PIM interfaces. One of the interfaces goes to PIM router B. The other interfaces go to leaf nodes, which are multicast end nodes attached to the router PIM interfaces. (For simplicity, the figure shows only one leaf node.)

When the arrow following an interface in the display points to a router address, this is the address of the next hop PIM router on that interface. In this example, PIM interface 207.95.8.1 on PIM router 207.95.8.1 is connected to PIM router 207.95.8.10. The connection can be a direct one or can take place through non-PIM routers. In this example, the PIM routers are directly connected.

When the arrow following an interface address points to zeros (0.0.0.0), the interface is not connected to a PIM router. The interface is instead connected to a leaf node.

NOTE

This display shows the PIM interface configuration information, but does not show the link states for the interfaces.

The information in brackets indicates the following:

- The multicast interface type (always PIM; this display is not supported in DVMRP)
- The Time-to-Live (TTL) for the interface.
- The metric for the interface
- Whether the interface is connected to a leaf node ("leaf" indicates a leaf node and blank indicates another PIM router)

For example, the information for the first interface listed in the display is "PIM/0 /1". This information indicates that the interface is a PIM interface, has a TTL of 0, and a metric of 1. The interface is not a leaf node interface and thus is an interface to another PIM router.

The information for the second interface in the display is “PIM/0 /1/leaf”. This information indicates that the interface is a PIM interface, has a TTL of 0 and a metric of 1, and is connected to a leaf node.

IGMP V3

The Internet Group Management Protocol (IGMP) allows an IPV4 interface to communicate IP Multicast group membership information to its neighboring routers. The routers in turn limit the multicast of IP packets with multicast destination addresses to only those interfaces on the router that are identified as IP Multicast group members. This release introduces the support of IGMP version 3 (IGMP V3) on Layer 3 switches.

In IGMP V2, when a router sent a query to the interfaces, the clients on the interfaces respond with a membership report of multicast groups to the router. The router can then send traffic to these groups, regardless of the traffic source. When an interface no longer needs to receive traffic from a group, it sends a leave message to the router which in turn sends a group-specific query to that interface to see if any other clients on the same interface is still active.

In contrast, IGMP V3 provides selective filtering of traffic based on traffic source. A router running IGMP V3 sends queries to every multicast enabled interface at the specified interval. These queries determine if any interface wants to receive traffic from the router. The queries include the IP address of the traffic source (S) or the ID of the multicast group (G, or both).

The interfaces respond to these queries by sending a membership report that contains one or more of the following records that are associated with a specific group:

- Current-State Record that indicates from which sources the interface wants to receive and not receive traffic. The record contains source address of interfaces and whether or not traffic will be received or included (IS_IN) or not received or excluded (IS_EX) from that source.
- Filter-mode-change record. If the interface changes its current state from IS_IN to IS_EX, a TO_EX record is included in the membership report. Likewise, if an interface current state changes from IS_EX to IS_IN, a TO_IN record appears in the membership report.

IGMP V2 Leave report is equivalent to a TO_IN(empty) record in IGMP V3. This record means that no traffic from this group will be received regardless of the source.

An IGMP V2 group report is equivalent to an IS_EX(empty) record in IGMP V3. This record means that all traffic from this group will be received regardless of source.

- Source-List-Change Record. If the interface wants to add or remove traffic sources from its membership report, the membership report can have an ALLOW record, which contains a list of new sources from which the interface wishes to receive traffic. It can also contain a BLOCK record, which lists current traffic sources from which the interfaces want to stop receiving traffic.

In response to membership reports from the interfaces, the router sends a Group-Specific or a Group-and-Source Specific query to the multicast interfaces. Each query is sent three times with a one-second interval in between each transmission to ensure the interfaces receive the query. For example, a router receives a membership report with a Source-List-Change record to block old sources from an interface. The router sends Group-and-Source Specific Queries to the source and group (S,G) identified in the record. If none of the interfaces is interested in the (S,G), it is removed from (S,G) list for that interface on the router.

Each IGMP V3-enabled router maintains a record of the state of each group and each physical port within a virtual routing interface. This record contains the group, group-timer, filter mode, and source records information for the group or interface. Source records contain information on the source address of the packet and source timer. If the source timer expires when the state of the group or interface is in Include mode, the record is removed.

Default IGMP version

IGMP V3 is available on Brocade devices; however, the devices are shipped with IGMP V2 enabled. You must enable IGMP V3 globally or per interface.

Also, you must specify what version of IGMP you want to run on a device globally, on each interface (physical port or virtual routing interface), and on each physical port within a virtual routing interface. If you do not specify an IGMP version, IGMP V2 will be used.

Compatibility with IGMP V1 and V2

Different multicast groups, interfaces, and routers can run their own version of IGMP. Their version of IGMP is reflected in the membership reports that the interfaces send to the router. Routers and interfaces must be configured to recognize the version of IGMP you want them to process.

An interface or router sends the queries and reports that include its IGMP version specified on it. It may recognize a query or report that has a different version, but it may not process them. For example, an interface running IGMP V2 can recognize IGMP V3 packets, but cannot process them. Also, a router running IGMP V3 can recognize and process IGMP V2 packet, but when that router sends queries to an IGMP V2 interface, the host on that interface may not recognize the IGMP V3 queries. The interface or router does not automatically downgrade the IGMP version running on them to avoid version deadlock.

If an interface continuously receives queries from routers that are running versions of IGMP that are different from what is on the interface, the interface logs warning messages in the syslog every five minutes. Reports sent by interfaces to routers that contain different versions of IGMP do not trigger warning messages; however, you can see the versions of the packets using the **show ip igmp traffic** command.

The version of IGMP can be specified globally, per interface (physical port or virtual routing interface), and per physical port within a virtual routing interface. The IGMP version set on a physical port within a virtual routing interface supersedes the version set on a physical or virtual routing interface. Likewise, the version on a physical or virtual routing interface supersedes the version set globally on the device. The sections below present how to set the version of IGMP.

Globally enabling the IGMP version

To globally identify the IGMP version on a Brocade device, enter the **ip igmp <version-number>** command.

```
Brocade(config)#ip igmp version 3
```

Syntax: **ip igmp version** <version-number>

Enter 1, 2, or 3 for <version-number>. Version 2 is the default version.

Enabling the IGMP version per interface setting

To specify the IGMP version for a physical port, enter a command such as the following.

```
Brocade(config)#interface eth 1/5
Brocade(config-if-1/5)#ip igmp version 3
```

To specify the IGMP version for a virtual routing interface on a physical port, enter a command such as the following.

```
Brocade(config)#interface ve 3
Brocade(config-vif-1) ip igmp version 3
```

Syntax: [no] ip igmp version <version-number>

Enter 1, 2, or 3 for <version-number>. Version 2 is the default version.

Enabling the IGMP version on a physical port within a virtual routing interface

To specify the IGMP version recognized by a physical port that is a member of a virtual routing interface, enter a command such as the following.

```
Brocade(config)#interface ve 3
Brocade(config-vif-3)#ip igmp version 2
Brocade(config-vif-3)#ip igmp port-version 3 e1/3-e1/7 e2/9
```

In this example, the second line sets IGMP V2 on virtual routing interface 3. However, the third line set IGMP V3 on ports 1/3 through 1/7 and port e2/9. All other ports in this virtual routing interface are configured with IGMP V2.

Syntax: ip igmp port-version <version-number> ethernet [<slotnum>/]<port-number>

Enter 1, 2, or 3 for <version-number>. IGMP V2 is the default version.

The **ethernet** <port-number> parameter specifies which physical port within a virtual routing interface is being configured. If you are entering this command on a chassis device, specify the slot number as well as the port number.

Enabling membership tracking and fast leave

IGMP V3 provides membership tracking and fast leave to clients. In IGMP V2, only one client on an interface needs to respond to a router queries; therefore, some of the clients may be invisible to the router, making it impossible for the router to track the membership of all clients in a group. Also, when a client leaves the group, the router sends group specific queries to the interface to see if other clients on that interface need the data stream of the client who is leaving. If no client responds, the router waits three seconds before it stops the traffic.

IGMP V3 contains the tracking and fast leave feature that you enable on virtual routing interfaces. Once enabled, all physical ports on that virtual routing interface will have the feature enabled. IGMP V3 requires all clients to respond to general and group specific queries so that all clients on an interface can be *tracked*. *Fast leave* allows clients to leave the group without the three second waiting period, if the following conditions are met:

- If the interface, to which the client belongs, has IGMP V3 clients only. Therefore, all physical ports on a virtual routing interface must have IGMP V3 enabled and no IGMP V1 or V2 clients can be on the interface. (Although IGMP V3 can handle V1 and V2 clients, these two clients cannot be on the interface in order for fast leave to take effect.)
- No other client on the interface is receiving traffic from the group to which the client belongs.

Every group on the physical interface of a virtual routing interface keeps its own tracking record. However, it can track group membership only; it cannot track by (source, group).

For example, two clients (Client A and Client B) belong to group1 but each is receiving traffic streams from different sources. Client A receives a stream from (source_1, group1) and Client B receives it from (source_2, group1). The router still waits for three seconds before it stops the traffic because the two clients are in the same group. If the clients are in different groups, then the three second waiting period is not applied and traffic is stopped immediately. The **show ip igmp group tracking** command displays that clients in a group that are being tracked.

If a client sends a leave message, the client is immediately removed from the group. If a client does not send a report during the the specified group membership time (the default is 140 seconds), that client is removed from the tracking list.

To enable the tracking and fast leave feature, enter commands such as the following.

```
Brocade(config)#interface ve 13
Brocade(config-vif-13)#ip igmp tracking
```

Syntax: **ip igmp tracking**

Setting the query interval

The IGMP query interval period defines how often a router will query an interface for group membership.

To modify the default value for the IGMP query interval, enter the **ip igmp query-interval <num>** command.

```
Brocade(config)#ip igmp query-interval 120
```

Syntax: **ip igmp query-interval <num>**

The <num> variable specifies the IGMP query interval in number of seconds. Enter a value from 10 through 3600. The default value is 125.

Setting the group membership time

The group membership time defines how long a group will remain active on an interface in the absence of a group report.

To define an IGMP membership time of 240 seconds, enter the **ip igmp group-membership-time <num>** command.

```
Brocade(config)#ip igmp group-membership-time 240
```

Syntax: **ip igmp group-membership-time <num>**

The <num> variable specifies the IGMP group membership time in number of seconds. Enter a value from 20 through 7200 seconds. The value you enter must be a little more than two times the query interval ($2 * \text{query-interval} + 10$). The default value is 260.

Setting the maximum response time

Maximum response time defines how long the Layer 3 switch will wait for an IGMP (V1 and V2) response from an interface before concluding that the group member on that interface is down, and then removing the interface from the group.

To change the IGMP maximum response time, enter the **ip igmp max-response-time <num>** command at the global CONFIG level of the CLI.

```
Brocade(config)#ip igmp max-response-time 8
```

Syntax: [no] ip igmp max-response-time <num>

The <num> parameter specifies the IGMP maximum response time in number of seconds. Enter a value from 1 through 10. The default is 10.

IGMP V3 and source-specific multicast protocols

Enabling IGMP V3 enables source specific multicast (SSM) filtering for DVMRP and PIM Dense (PIM-DM) for multicast group addresses in the 224.0.1.0 through 239.255.255.255 address range. However, if PIM Sparse is used as the multicast protocol, the SSM protocol should be enabled if you want to filter unwanted traffic before the Shortest Path Tree protocol switchover occurs for groups in the 232/8 range. Not configuring the SSM protocol in PIM Sparse may cause the switch or router to leak unwanted packets with the same group, but containing undesired sources, to clients. After SPT switch over, the leak stops and source specific multicast works correctly even without configuring the SSM protocol.

If the SSM protocol is not enabled and before the SPT switchover, the multicast router creates one (*, G) entry for the entire multicast group, which can have many sources. If the SSM protocol is enabled, one (S,G) entry is created for every member of the multicast group, even for members with non-existent traffic. For example, if there are 1,000 members in the group, 1,000 (S,G) entries will be created. Therefore, enabling the SSM protocol for PIM-SM requires more resources than leaving the protocol disabled.

Enabling SSM

To enable the SSM protocol on a Brocade device running PIM-SM, enter a command such as the following.

```
Brocade(config)#router pim
Brocade(config-pim-router)#ssm-enable
```

Syntax: [no] ssm-enable

Enter the ssm-enable command under the router pim level to globally enable the SSM protocol on a Layer 3 switch.

Displaying IGMP V3 information on Layer 3 switches

The sections below present the show commands available for IGMP V3 on Layer 3 switches. For show commands on Layer 2 Switches, use the **show ip multicast** commands which are discussed in the section [“IGMP snooping show commands”](#) on page 1477.

Displaying IGMP group status

NOTE

This report is available on Layer 3 switches.

To display the status of all IGMP multicast groups on a device, enter the **ip igmp group** command.

```
Brocade#show ip igmp group
p-:physical, ST:static, QR:querier, EX:exclude, IN: include, Y:yes, N:no
v101 : 1 groups, 1 group-port
      group      p-port      ST      QR      life mode      source
1       239.200.1.1  1/1/11    no      no      260    EX      0
```

To display the status of one IGMP multicast group, enter a command such as the following.

```
Brocade#show ip igmp group 239.0.0.1 detail
Display group 239.0.0.1 in all interfaces.
Interface v18 : 1 groups
      group      phy-port static querier life mode      #_src
1       239.0.0.1  e4/20    no      yes      include 19
group: 239.0.0.1, include, permit 19 (source, life):
(3.3.3.1 40) (3.3.3.2 40) (3.3.3.3 40) (3.3.3.4 40) (3.3.3.5 40)
(3.3.3.6 40) (3.3.3.7 40) (3.3.3.8 40) (3.3.3.9 40) (3.3.3.10 40)
(3.3.3.11 40) (3.3.3.12 40) (3.3.3.13 40) (3.3.3.14 40) (3.3.3.15 40)
(3.3.3.16 40) (3.3.3.17 40) (3.3.3.18 40) (3.3.3.19 40)
Interface v110 : 1 groups
      group      phy-port static querier life mode      #_src
2       239.0.0.1  e4/5     no      yes      include 10
group: 239.0.0.1, include, permit 10 (source, life):
(2.2.3.0 80) (2.2.3.1 80) (2.2.3.2 80) (2.2.3.3 80) (2.2.3.4 80)
(2.2.3.5 80) (2.2.3.6 80) (2.2.3.7 80) (2.2.3.8 80) (2.2.3.9 80)
```

If the tracking and fast leave feature is enabled, you can display the list of clients that belong to a particular group by entering commands such as the following.

```
Brocade#show ip igmp group 224.1.10.1 tracking
Display group 224.1.10.1 in all interfaces with tracking enabled.
Interface v13 : 1 groups, tracking_enabled
      group      phy-port static querier life mode      #_src
1       224.1.10.1  e4/15    no      yes      include 3
receive reports from 3 clients:
110.110.110.7 110.110.110.8 110.110.110.9
```

Syntax: **show ip igmp group** [<group-address>] [**detail** | **tracking**]

If you want a report for a specific multicast group, enter that group address for <group-address>. Omit the <group-address> if you want a report for all multicast groups.

Enter **detail** if you want to display the source list of the multicast group.

Enter **tracking** if you want information on interfaces that have tracking enabled.

The following table defines the statistics for the **show ip igmp group** command output.

TABLE 270 Output of show ip igmp group

Field	Description
Group	The address of the multicast group
Phy-port	The physical port on which the multicast group was received.
Static	A “yes” entry in this column indicates that the multicast group was configured as a static group; “No” means it was not. Static multicast groups can be configured in IGMP V2 using the ip igmp static command. In IGMP V3, static sources cannot be configured in static groups.
Querier	“Yes” means that the port is a querier port; “No” means it is not. A port becomes a non-querier port when it receives a query from a source with a lower source IP address than the port.
Life	Shows the number of seconds the interface can remain in exclude mode. An exclude mode changes to include mode if it does not receive an "IS_EX" or "TO_EX" message during a certain period of time. The default is 140 seconds. There is no "life" displayed in include mode.
Mode	Indicates current mode of the interface: Include or Exclude. If the interface is in Include mode, it admits traffic only from the source list. If an interface is in Exclude mode, it denies traffic from the source list and accepts the rest.
#_src	Identifies the source list that will be included or excluded on the interface. If IGMP V2 group is in Exclude mode with a #_src of 0, the group excludes traffic from 0 (zero) source list, which means that all traffic sources are included.
Group:	<p>If you requested a <i>detailed</i> report, the following information is displayed:</p> <ul style="list-style-type: none"> • The multicast group address • The mode of the group • A list of sources from which traffic will be admitted (include) or denied (exclude) on the interface is listed. • The life of each source list. <p>If you requested a <i>tracking</i> report, the clients from which reports were received are identified.</p>

Displaying the IGMP status of an interface

You can display the status of a multicast enabled port by entering the **ip igmp interface** command.

NOTE

This report is available on Layer 3 switches.

```

Brocade#show ip igmp interface
query interval = 60, max response time= 3, group membership time=140
v5: default V2,          PIM dense, addr=1.1.1.2
   e4/12  has    0 groups, non-Querier (age=40), default V2
v18: default V2,         DVMRP, addr=2.2.2.1
   e4/20  has    0 groups, Querier, default V2
v20: configured V3,      PIM dense (port down), addr=1.1.20.1
v110: configured V3,     PIM dense, addr=110.110.110.1
   e4/6   has    2 groups, Querier, default V3
       group: 239.0.0.1, exclude, life=100, deny 13
       group: 224.1.10.1, include, permit 2
   e4/5   has    3 groups, Querier, default V3
       group: 224.2.2.2, include, permit 100
       group: 239.0.0.1, include, permit 10
       group: 224.1.10.1, include, permit 1

```

Syntax: `show ip igmp interface [ve | ethernet <number> <group-address>]`

Enter **ve** and its <number> or **ethernet** and its <number> to display information for a specific virtual routing interface or ethernet interface.

Entering an address for <group-address> displays information for a specified group on the specified interface.

The report shows the following information.

TABLE 271 Output of show ip igmp interface

Field	Description
Query interval	Displays how often a querier sends a general query on the interface.
Max response	The maximum number of seconds a client can wait before it replies to the query.
Group membership time	The number of seconds multicast groups can be members of this group before aging out.
(details)	<p>The following is displayed for each interface:</p> <ul style="list-style-type: none"> • The ID of the interface • The IGMP version that it is running (default IGMP V2 or configured IGMP V3) • The multicast protocol it is running: DVMRP, PIM-DM, PIM-SM • Address of the multicast group on the interface • If the interface is a virtual routing interface, the physical port to which that interface belongs, the number of groups on that physical port, whether or not the port is a querier or a non-querier port, the age of the port, and other multicast information for the port are displayed.

Displaying IGMP traffic status

To display the traffic status on each virtual routing interface, enter the **show ip igmp traffic** command.

NOTE

This report is available on Layer 3 switches.

```
Brocade#show ip igmp traffic

```

Syntax: show ip igmp traffic

The report shows the following information.

TABLE 272 Output of show ip igmp traffic

Field	Description
QryV2	Number of general IGMP V2 query received or sent by the virtual routing interface.
QryV3	Number of general IGMP V3 query received or sent by the virtual routing interface.
G-Qry	Number of group specific query received or sent by the virtual routing interface.
GSQry	Number of source specific query received or sent by the virtual routing interface.
MbrV2	The IGMP V2 membership report.
MbrV3	The IGMP V3 membership report.
Leave	Number of IGMP V2 "leave" messages on the interface. (See ToEx for IGMP V3.)
IsIN	Number of source addresses that were included in the traffic.
IsEX	Number of source addresses that were excluded in the traffic.
ToIN	Number of times the interface mode changed from exclude to include.
ToEX	Number of times the interface mode changed from include to exclude.
ALLOW	Number of times that additional source addresses were allowed or denied on the interface.
BLK	Number of times that sources were removed from an interface.

Clearing IGMP statistics

To clear statistics for IGMP traffic, enter the **clear igmp traffic** command.

```
Brocade#clear igmp traffic
```

Syntax: clear igmp traffic

This command clears all the multicast traffic information on all interfaces on the device.

IGMP Proxy

IGMP Proxy provides a means for the FastIron X Series routers to receive any or all multicast traffic from an upstream device if the router is not able to run PIM.

IGMP Proxy enables the router to issue IGMP host messages on behalf of hosts that the router discovered through standard PIM interfaces. The router acts as a proxy for its hosts and performs the host portion of the IGMP task on the upstream interface as follows:

- When queried, the router sends group membership reports for the groups learned
- When one of its hosts joins a multicast address group to which none of its other hosts belong, the router sends unsolicited membership reports to that group.
- When the last of its hosts in a particular multicast group leaves the group, the FastIron X Series router sends an unsolicited leave group membership report to group for all routers (multicast IP address 224.0.0.2)

IGMP proxy configuration notes

When using IGMP Proxy, you must do the following.

1. Configure PIM on all multicast client ports to build the group membership table. The group membership table will be reported by the proxy interface. Refer to [“Globally enabling and disabling PIM”](#) on page 1525.
2. Enable IP multicast on an interface to an upstream FastIron X Series router that will be the IGMP proxy interface and configure IGMP Proxy on that interface

IGMP proxy limitations

- IGMP Proxy cannot be enabled on the same interface on which PIM SM, PIM DM, or DVMRP is enabled.
- IGMP Proxy is only supported in a PIM Dense environment where there are IGMP clients connected to the Brocade device. The Brocade device will not send IGMP reports on an IGMP proxy interface for remote clients connected to a PIM neighbor, as it will not be aware of groups that the remote clients are interested in.

Configuring IGMP Proxy

Perform the following steps to configure IGMP Proxy.

1. Configure router PIM globally.

```
Brocade(config)#router pim
```
2. Configure an IP address on the interface (physical or virtual routing interface) that will serve as the IGMP proxy for an upstream device by entering commands such as the following.

```
Brocade(config)#int e 1/3
Brocade(config-if-e1000-1/3)#ip address 207.95.5.1/24
```
3. Enable IGMP Proxy on the interface.

```
Brocade(config-if-e1000-1/3)#ip igmp proxy
```

Syntax: [no] ip igmp proxy

Once IGMP Proxy is configured and the FastIron X Series router receives a query on an IGMP Proxy interface, the router sends a report in response to the query before the IGMP maximum response time expires.

Displaying IGMP Proxy traffic

Use the **show ip igmp traffic** command to see traffic for IGMP Proxy.

```
Brocade#show ip igmp traffic
```

Recv	QryV2	QryV3	G-Qry	GSQry	MbrV2	MbrV3	Leave	IsIN	IsEX	ToIN	ToEX	ALLO	BLK
e1/14	0	0	0	0	27251	0	12	0	27251	12	0	0	0
v10	250	0	0	0	244	0	0	0	244	0	0	0	0
Send	QryV1	QryV2	QryV3	G-Qry	GSQry	MbrV1	Mbrv2	Leave					
e1/14	0	1365	0	48	0	0	0	0					
v10	0	1	0	0	0	0	25602	1					

Syntax: show ip igmp traffic

Refer to [“Displaying IGMP traffic status”](#) on page 1604 to interpret the information in the output. The fields in bold show information for IGMP Proxy.

IP multicast protocols and IGMP snooping on the same device

The Brocade device supports global Layer 2 IP multicast traffic reduction (IGMP snooping) and Layer 3 multicast routing (DVMRP or PIM-Sparse or PIM-Dense) together on the same device in the full Layer 3 software image, as long as the Layer 2 feature configuration is at the VLAN level.

For Layer 2 multicast traffic reduction, IGMP snooping is performed independently within all VLANs that have the feature configured. Layer 3 multicast routing is performed between the IP interfaces that are configured for DVMRP, PIM-Sparse, or PIM-Dense. A Layer 3 interface could be a physical, loopback, or VE port configured with an IP address.

If there are two sources for a single group, where one source sends traffic into a VLAN with IGMP snooping enabled, while the other source sends traffic to a PIM enabled Layer 3 interface, a client for the group in the same VLAN as the first source will only receive traffic from that source. It will not receive traffic from the second source connected to the Layer 3 interface. Similarly, if there is another IP interface with a Layer 3 client or PIM or DVMRP neighbor that requests traffic for the same group, it will only receive traffic from the second source and not the first.

IP multicast protocols and IGMP snooping configuration example

Figure 182 and Figure 183 show an example IGMP snooping and PIM forwarding configuration.

FIGURE 182 Example 1: IGMP Snooping and PIM forwarding

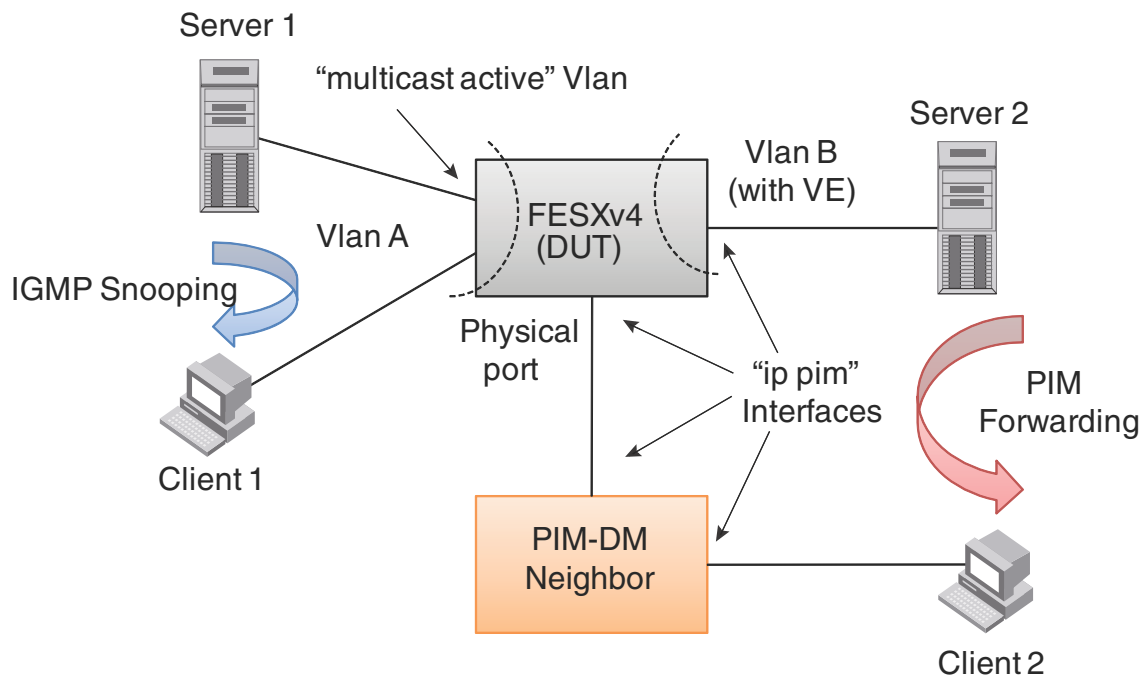

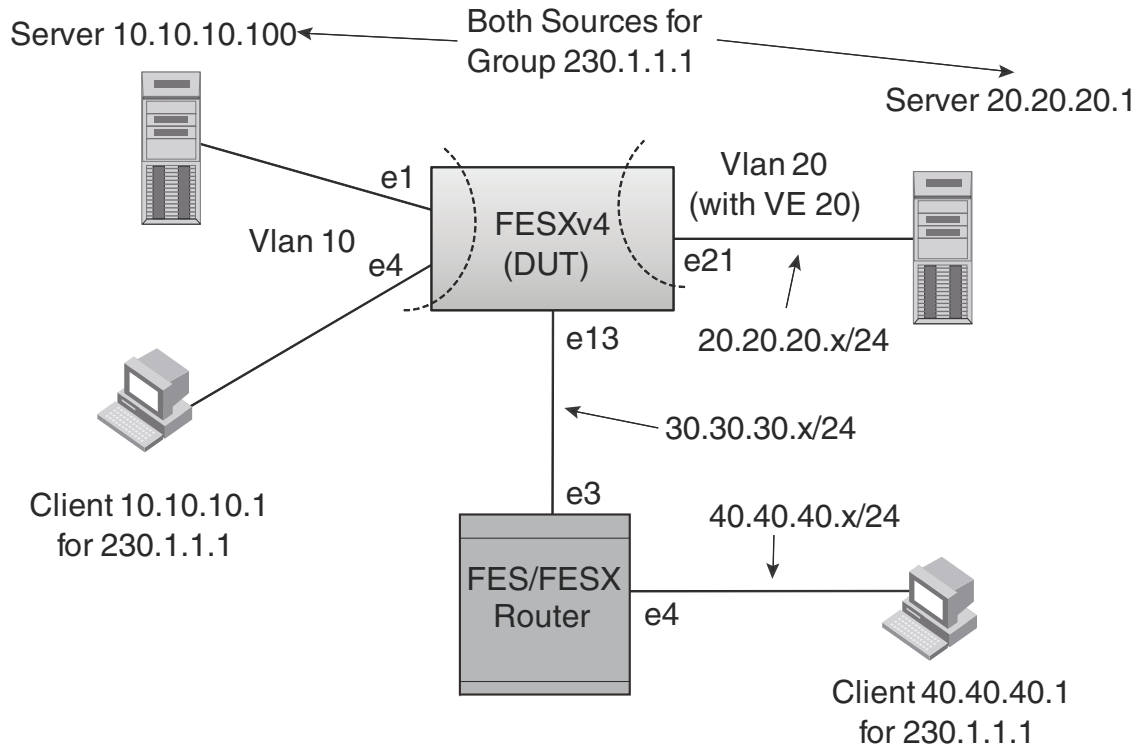

FIGURE 183 Example 2: IGMP Snooping and PIM Forwarding

IP multicast protocols and IGMP snooping CLI commands

The following are the CLI commands for the configuration example shown in [Figure 182](#) and [Figure 183](#).

1. On the FESXv4 device, configure IGMP Snooping on VLAN 10.

```
Brocade(config)#vlan 10 by port
Brocade(config-vlan-10)#untagged e 1 to 4
Added untagged port(s) ethe 1 to 4 to port-vlan 10.
Brocade(config-vlan-10)#router-interface ve 10
Brocade(config-vlan-10)#ip multicast active
Brocade(config-vlan-10)#interface ve 10
Brocade(config-vif-10)#ip address 10.10.10.10/24
```

2. On the FESXv4 device, enable PIM routing between VLAN/VE 20 and Interface e 13.

```
Brocade(config)#vlan 20 by port
Brocade(config-vlan-20)#untagged e 21 to 24
Added untagged port(s) ethe 21 to 24 to port-vlan 20.
Brocade(config-vlan-20)#router-interface ve 20
Brocade(config-vlan-20)#exit
Brocade(config)#router pim
Brocade(config-pim-router)#exit
Brocade(config)#interface ve 20
Brocade(config-vif-20)#ip address 20.20.20.10/24
Brocade(config-vif-20)#ip pim
```

```
Brocade(config-vif-20)#exit
Brocade(config)#interface e 13
Brocade(config-if-e1000-13)#ip address 30.30.30.10/24
Brocade(config-if-e1000-13)#ip pim
```

3. Configure the FES/FESX neighboring device.

```
Brocade(config)#ip route 20.20.20.0 255.255.255.0 30.30.30.10
Brocade(config)#router pim
Brocade(config-pim-router)#exit
Brocade(config)#interface ethernet 3
Brocade(config-if-e1000-3)#ip address 30.30.30.20/24
Brocade(config-if-e1000-3)#ip pim
Brocade(config-if-e1000-3)#interface ethernet 4
Brocade(config-if-e1000-4)#ip address 40.40.40.20/24
Brocade(config-if-e1000-4)#ip pim
```

IP multicast protocols and IGMP snooping on the same device

MLD Snooping on FastIron X Series Switches

[Table 273](#) lists the individual Brocade FastIron switches and the Multicast Listening Discovery (MLD) snooping features they support. These features are supported in the Layer 2, base Layer 3, and full Layer 3 software images.

TABLE 273 Supported MLD snooping features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
MLD V1/V2 snooping (global and local)	Yes	This chapter describes MLD snooping on the FESX, FSX 800 and FSX 1600. For information about MLD snooping on other FastIron devices, see Chapter 38 , “MLD Snooping on FastIron WS and Brocade FCX and ICX Switches”.			
MLD fast leave for V1	Yes				
MLD tracking and fast leave for V2	Yes				
Static MLD and IGMP groups with support for proxy	Yes				

MLD Snooping Overview

The default method a device uses to process an IPv6 multicast packet is to broadcast it to all ports except the incoming port of a VLAN. Packets are flooded by hardware without going to the CPU, which may result in some clients receiving unwanted traffic.

If a VLAN is not Multicast Listening Discovery (MLD) snooping-enabled, it floods IPv6 multicast data and control packets to the entire VLAN in hardware. When snooping is enabled, MLD packets are trapped to the CPU. Data packets are mirrored to the CPU and flooded to the entire VLAN. The CPU then installs hardware resources so subsequent data packets can be hardware-switched to desired ports without going through the CPU. If there is no client report, the hardware resource drops the data stream.

MLD protocols provide a way for clients and a device to exchange messages, and allow the device to build a database indicating which port wants what traffic. Since the MLD protocols do not specify forwarding methods, MLD snooping or multicast protocols such as IPv6 PIM-Sparse Mode (PIM SM) are required to handle packet forwarding. PIM SM can route multicast packets within and outside a VLAN, while MLD snooping can switch packets only within a VLAN. FESX and FSX devices do not support PIM-SM routing.

MLD snooping provides multicast containment by forwarding traffic only to those clients that have MLD receivers for a specific multicast group (destination address). The device maintains the MLD group membership information by processing MLD reports and generating messages so traffic can be forwarded to ports receiving MLD reports. This is analogous to IGMP Snooping on Brocade Layer 3 switches.

An IPv6 multicast address is a destination address in the range of FF00::/8. A limited number of multicast addresses are reserved. Since packets destined for the reserved addresses may require VLAN flooding, FESX and FSX devices do not snoop in the FFOX::00X range (where X is from 00 to FF). Data packets destined to these addresses are flooded to the entire VLAN by hardware and mirrored to the CPU. Multicast data packets destined to addresses outside the FFOX::00X range are snooped. A client must send MLD reports in order to receive traffic.

An MLD device periodically broadcasts general queries and sends group queries upon receiving a leave message, to ensure no other clients at the same port still want this specific traffic before removing it. MLDv1 allows clients to specify which group (destination IPv6 address) will receive traffic. (MLDv1 cannot choose the source of the traffic.) MLDv2 deals with source-specific multicasts, adding the capability for clients to INCLUDE or EXCLUDE specific traffic sources. An MLDv2 device's port state can either be in INCLUDE or EXCLUDE mode.

There are different types of group records for client reports. Clients respond to general queries by sending a membership report containing one or more of the following records associated with a specific group:

- **Current-state record** - Indicates the sources from which the client wants to receive or not receive traffic. This record contains the source addresses of the clients and indicates whether or not traffic will be included (IS_IN) or excluded (IS_EX) from that source address.
- **Filter-mode-change record** - If the client changes its current state from IS_IN to IS_EX, a TO_EX record is included in the membership report. Likewise, if a client current state changes from IS_EX to IS_IN, a TO_IN record appears in the membership report.
- **MLDv1 leave report** - Equivalent to a TO_IN (empty) record in MLDv2. This record means that no traffic from this group will be received, regardless of the source.
- **An MLDv1 group report** - Equivalent to an IS_EX (empty) record in MLDv2. This record means that all traffic from this group will be received, regardless of the source.
- **Source-list-change record** - If the client wants to add or remove traffic sources from its membership report, the report can include an ALLOW record, which contains a list of new sources from which the client wishes to receive traffic. The report can also contain a BLOCK record, which lists current traffic sources from which the client wants to stop receiving traffic.

How MLD snooping uses MAC addresses to forward multicast packets

Multicast Listening Discovery (MLD) snooping on Brocade devices is based on MAC address entries. When an IPv6 multicast data packet is received, the packet destination MAC is matched with the MAC address entries in the IPv6 multicast table. If a match is found, packets are sent to the ports associated with the MAC address. If a match is not found, packets are flooded to the VLAN and copied to the CPU.

For IPv6 multicast, the destination MAC address is in the format 0x33-33-xx-yy-zz-kk, where xx-yy-zz-kk are the 32 lowest bits of the IPv6 multicast group address. For example, the IPv6 group address 0xFF3E:40:2001:660:3007:123:1234:5678 maps to the IPv6 MAC address 0x33-33-12-34-56-78.

For two multicast traffic streams, Source_1 and Group1 (S1,G1) and Source_2 and Group2 (S2,G2), with the same or different source addresses, if the lowest 32 bits of the 128-bit IPv6 group address are the same, they would map to the same destination MAC. Because the FESX and FSX support MAC-based forwarding for MLD snooping, the final multicast MAC address entry would be a superset of all the IPv6 groups mapped to it. For example, consider the following three IPv6 multicast streams sent from port 5 of a Brocade device:

- (S1,G1) = (2060::5, ff1e::12), client port 1, port 2
- (S2,G2) = (2060::6, ff1e::12), client port 2, port 3
- (S3,G1) = (2060::7, ff1e::12), client port 4

Because the lowest 32 bits of the group address for G1 and G2 are the same, all three streams would use 0x33-33-00-00-00-12 as the destination MAC address. MLD snooping would build a MAC entry with the MAC address 0x33-33-00-00-00-12 on egress ports 1, 2, 3, and 4. As a result, all three streams would be sent to ports 1, 2, 3, and 4. Note that the above example assumes the following:

- The Brocade device is running MLD snooping on VLAN 10 and all three streams are in VLAN 10
- There are clients on port 1 and port 2 for (S1,G1)
- There are clients on port 2 and port 3 for (S2,G2)
- There are clients on port 4 for (S3,G1)

MLD snooping configuration notes and feature limitations

- Servers (traffic sources) are not required to send Multicast Listening Discovery (MLD) memberships.
- The default MLD version is V1, where the source address is not sensitive. In the example given in the preceding section ([“How MLD snooping uses MAC addresses to forward multicast packets”](#) on page 1612), (S1,G1) and (S3,G1) would be considered the same group as (*,G1).
- If MLDv2 is configured on any port of a VLAN, you can check the source information, but because MLD snooping is MAC based, (S,G) switching is not feasible.
- Hardware resources are installed only when there is data traffic.
- Up to 4K collective entries for IGMP Snooping, MLD snooping, and Multi-port Static MAC Addresses are supported.
- You can configure the maximum number of groups and the multicast cache (mcache) number.
- The device supports static groups applying to specific ports. The device acts as a proxy to send MLD reports for the static groups when receiving queries.
- A user can configure static router ports, forcing all multicast traffic to be sent to these ports.
- Brocade devices support fast leave for MLDv1, which stops traffic immediately to any port that has received a leave message.
- Brocade devices support tracking and fast leave for MLDv2, which tracks all MLDv2 clients. If the only client on a port leaves, traffic is stopped immediately.
- An MLD device can be configured as a querier (active) or non-querier (passive). Queriers send queries. Non-queriers listen for queries and forward them to the entire VLAN.
- Every VLAN can be independently configured as a querier or a non-querier.

- A VLAN that has a connection to an IPv6 PIM-enabled port on another router should be configured as a non-querier. When multiple snooping devices connect together and there is no connection to IPv6 PIM ports, only one device should be configured as the querier. If multiple devices are configured as active, only one will continue to send queries after the devices have exchanged queries. Refer to [“MLD snooping-enabled queriers and non-queriers”](#) on page 1614.
- An MLD device can be configured to rate-limit the forwarding of MLDv1 membership reports to queriers.
- Because an IPv6 link-local address as the source address when sending queries, a global address is not required.
- The MLD implementation allows snooping on some VLANs or on all VLANs. MLD can be enabled or disabled independently for each VLAN. In addition, individual ports of a VLAN can be configured as MLDv1 and MLDv2. In general, global configuration commands such as **ipv6 mld-snooping..** apply to all VLANs except those with a local **mld-snooping..** configuration, which supersedes the global configuration. Configuring the version on a port or a VLAN only affects the device sent query version. The device always processes all versions of client reports regardless of the version configured.
- MLD snooping requires hardware resources. If the device has insufficient resources, the data stream without a resource is mirrored to the CPU in addition to being VLAN flooded, which can cause high CPU usage. To avoid this situation, Brocade recommends that you avoid enabling snooping globally unless necessary.
- To receive data traffic, MLD snooping requires clients to send membership reports. If a client does not send reports, you must configure a static group to force traffic to client ports.
- Multicast Router Discovery (MRD) messages are useful for determining which nodes attached to a switch have multicast routing enabled. This capability is useful in a Layer 2 bridge domain with snooping switches. By utilizing MRD messages, Layer 2 switches can determine where to send multicast source data and group membership messages. Multicast source data and group membership reports must be received by all multicast routers on a segment. Using the group membership protocol Query messages to discover multicast routers is insufficient due to query suppression.

Since Brocade does not support MRD, this can lead to stream loss when non-Querier router ports age out on the Querier after the initial Query election. To avoid such stream loss, configure a static router port on the querier on each interface that connects to a non-querier snooping device.

MLD snooping-enabled queriers and non-queriers

An MLD snooping-enabled device can be configured as a querier (active) or non-querier (passive). An MLD querier sends queries; a non-querier listens for MLD queries and forwards them to the entire VLAN. When multiple MLD snooping devices are connected together, and there is no connection to an IPv6 PIM-enabled port, one of the devices should be configured as a querier. If multiple devices are configured as queriers, after multiple devices exchange queries, then all devices except the winner (the device with the lowest address) stop sending queries. Although the system works when multiple devices are configured as queriers, Brocade recommends that only one device, preferably the one with the traffic source, is configured as the querier.

VLANs can also be independently configured as queriers or non-queriers. If a VLAN has a connection to an IPv6 PIM-enabled port on another router, the VLAN should be configured as a non-querier.

Because non-queriers always forward multicast data traffic and MLD messages to router ports which receive MLD queries or IPv6 PIM hellos, Brocade recommends that you configure the devices with the data traffic source (server) as queriers. If a server is attached to a non-querier, the non-querier always forwards traffic to the querier regardless of whether or not there are clients on the querier.

NOTE

In a topology with one or more connected devices, at least one device must be running PIM, or configured as active. Otherwise, no devices can send queries, and traffic cannot be forwarded to clients.

To configure the MLD mode (querier or non-querier) on an MLD snooping-enabled device, refer to [“Configuring the global MLD mode”](#) on page 1617. To configure the MLD mode on a VLAN, refer to [“Configuring the MLD mode for a VLAN”](#) on page 1619.

MLD and VLAN configuration

You can configure MLD snooping on some VLANs or all VLANs. Each VLAN can be independently enabled or disabled for MLD snooping, or can be configured with MLDv1 or MLDv2. In general, the **ipv6 mld-snooping...** commands apply globally to all VLANs except those configured with VLAN-specific **mld-snooping...** commands. VLAN-specific **mld-snooping** commands supersede global **ipv6 mld-snooping** commands.

MLDv1 with MLDv2

MLD snooping can be configured as MLDv1 or MLDv2 on individual ports on a VLAN. An interface or router sends queries and reports that include the MLD version with which it has been configured. The version configuration applies only to the sending of queries. The snooping device recognizes and processes MLDv1 and MLDv2 packets regardless of the version configured.

NOTE

To avoid version deadlock, when an interface receives a report with a lower version than that for which it has been configured, the interface does **not** automatically downgrade the running MLD version.

MLD snooping configuration

Configuring Multicast Listening Discovery (MLD) snooping on an IPv6 device consists of the following global and VLAN-specific tasks.

MLD snooping global tasks

- Configuring hardware and software resource limits
- Disabling transmission and receipt of MLD packets on a port
- Configuring the MLD mode: active or passive (must be enabled for MLD snooping)
- Modifying the age interval
- Modifying the interval for query messages (active MLD mode only)
- Specifying the global MLD version
- Enabling and disabling report control (rate limiting)

- Modifying the leave wait time
- Modifying the mcache age interval
- Disabling error and warning messages

MLD snooping VLAN-specific tasks:

- Configuring the MLD mode for the VLAN: active or passive
- Enabling or disabling MLD snooping for the VLAN
- Configuring the MLD version for the VLAN
- Configuring the MLD version for individual ports
- Configuring static groups to the entire VLAN or some ports
- Configuring static router ports
- Disabling proxy activity for a static group
- Enabling client tracking and the fast leave feature for MLDv2
- Configuring fast leave for MLDv1
- Configuring fast-convergence

Configuring the hardware and software resource limits

The system supports up to 8K of hardware-switched multicast streams. The default is 512. To define the maximum number of MLD snooping mcache entries, enter the **system-max mld-snoop-mcache** *<num>* command.

```
Brocade(config)#system-max mld-snoop-mcache 8000
```

Syntax: [no] **system-max mld-snoop-mcache** *<num>*

<num> is a value from 256 – 8192. The default is 512.

The system supports up to 32K of multicast groups. The default is 8192. The configured number is the upper limit of an expandable database. Client memberships exceeding the group limits are not processed. To define the maximum number of multicast group addresses supported, enter the **system-max mld-max-group-addr** *<num>* command.

```
Brocade(config)#system-max mld-max-group-addr 4000
```

Syntax: [no] **system-max mld-snoop-mcache** *<num>*

<num> is a value from 256 – 32768. The default is 8192.

Disabling transmission and receipt of MLD packets on a port

When a VLAN is snooping-enabled, all MLD packets are trapped to the CPU without hardware VLAN flooding. The CPU can block MLD packets to and from a multicast-disabled port, and will not add that port to the output interfaces of hardware resources, which prevents the disabled port from receiving multicast traffic. However, if static groups to the entire VLAN are defined, the traffic for these groups is flooded to the entire VLAN, including to the disabled ports. Since the hardware cannot block traffic from disabled ports, hardware traffic is switched in the same way as traffic from enabled ports.

NOTE

This command has no effect on a VLAN that is not snooping-enabled because all multicast traffic is VLAN flooded.

```
Brocade(config)#interface ethernet 1/3
Brocade(config-if-e1000-1/3)#ipv6-multicast-disable
```

Syntax: [no] **ipv6-multicast-disable**

Configuring the global MLD mode

You can configure a Brocade device for either active or passive (default) MLD mode. If you specify an MLD mode for a VLAN, the MLD mode overrides the global setting.

- **Active** – In active MLD mode, a device actively sends out MLD queries to identify IPv6 multicast groups on the network, and makes entries in the MLD table based on the group membership reports it receives from the network.
- **Passive** – In passive MLD mode, the device forwards reports to the router ports which receive queries. MLD snooping in passive mode does not send queries, but does forward queries to the entire VLAN.

To globally set the MLD mode to active, enter the **ipv6 mld-snooping active** command.

```
Brocade(config)#ipv6 mld-snooping active
```

Syntax: [no] **ipv6 mld-snooping** [active | passive]

Omitting both the **active** and **passive** keywords is the same as entering **ipv6 mld-snooping passive**.

Modifying the age interval

When the device receives a group membership report, it makes an entry in the MLD group table for the group in the report. The age interval specifies how long the entry can remain in the table without the device receiving another group membership report. When multiple devices connect together, all devices should be configured with the same age interval. The age interval should be at least twice that of the query interval, so that missing one report will not stop traffic. For a non-querier, the query interval should equal that of the querier.

To modify the age interval, enter a command such as the following.

```
Brocade(config)#ipv6 mld-snooping age-interval 280
```

Syntax: [no] **ipv6 mld-snooping age-interval** <interval>

The <interval> parameter specifies the aging time. You can specify a value from 20 – 7200 seconds. The default is 140 seconds.

Modifying the query interval (active MLD snooping mode only)

If the MLD mode is set to active, you can modify the query interval, which specifies how often the Brocade device sends group membership queries. By default, queries are sent every 60 seconds. When multiple queriers connect together, all queriers should be configured with the same interval.

To modify the query interval, enter the **ipv6 mld-snooping query-interval** <num> command.

```
Brocade(config)#ipv6 mld-snooping query-interval 120
```

Syntax: [no] ipv6 mld-snooping query-interval <interval>

The <interval> parameter specifies the interval between queries. You can specify a value from 10 – 3600 seconds. The default is 60 seconds.

Configuring the global MLD version

The default version is MLDv1. You can specify the global MLD version on the device as either MLDv1 or MLDv2. For example, the following command configures the device to use MLDv2.

```
Brocade(config)#ipv6 mld-snooping version 2
```

Syntax: [no] ipv6 mld-snooping version 1 | 2

You can also specify the MLD version for individual VLANs, or individual ports within VLANs. If no MLD version is specified for a VLAN, then the globally configured MLD version is used. If an MLD version is specified for individual ports in a VLAN, those ports use that version instead of the version specified for the VLAN or the globally specified version. The default is MLDv1.

Configuring report control

When a device is in passive mode, it forwards reports and leave messages from clients to the upstream router ports that are receiving queries.

You can configure report control to rate-limit report forwarding for the same group to no more than once per 10 seconds. This rate limiting does not apply to the first report answering a group-specific query.

NOTE

This feature applies to MLDv1 only. The leave messages are not rate limited.

MLDv1 membership reports for the same group from different clients are considered to be the same, and are rate-limited. This alleviates the report storm caused by multiple clients answering the upstream router query.

To enable report-control, enter the **ipv6 mld-snooping report-control** command.

```
Brocade(config)#ipv6 mld-snooping report-control
```

Syntax: [no] ipv6 mld-snooping report-control

Modifying the wait time before stopping traffic when receiving a leave message

You can define the wait time before stopping traffic to a port when the device receives a leave message for that port. The device sends group-specific queries once per second to determine if any client on the same port still needs the group.

```
Brocade(config)#ipv6 mld-snooping leave-wait-time 1
```

Syntax: [no] ipv6 mld-snooping leave-wait-time <num>

where <num> is a value from 1 to 5. The default is 2. Because of the internal timer accuracy, the actual wait time is between n and (n+1) seconds, where n is the configured value.

Modifying the multicast cache (mcache) aging time

You can set the time for an mcache to age out when it does not receive traffic. Two seconds before an mcache is aged out, the device mirrors a packet of the mcache to the CPU to reset the age. If no data traffic arrives within two seconds, the mcache is deleted. Note that in FESX and FSX devices, more than one mcache can be mapped to the same destination MAC. Hence, when an mcache entry is deleted, the MAC entry may not be deleted. If you configure a lower value, the resource consumed by idle streams is quickly removed, but packets are mirrored to the CPU more frequently. Configure a higher value only when data streams are arriving consistently.

You can use the **show ipv6 mld-snooping mcache** command to view the currently configured mcache age. Refer to [“Displaying MLD snooping mcache information”](#) on page 1625.

To modify the multicast cache age out time, enter the **ipv6 mld-snooping mcache-age <num>** command.

```
Brocade(config)#ipv6 mld-snooping mcache-age 180
```

Syntax: [no] **ipv6 mld-snooping mcache-age <num>**

where <num> is a value from 60 to 3600 seconds, and the default is 60 seconds.

Disabling error and warning messages

Error or warning messages are printed when the device runs out of software resources or when it receives packets with the wrong checksum or groups. These messages are rate limited. You can turn off these messages by entering the **ipv6 mld-snooping verbose-off** command.

```
Brocade(config)#ipv6 mld-snooping verbose-off
```

Syntax: [no] **ipv6 mld-snooping verbose-off**

Configuring the MLD mode for a VLAN

You can configure a VLAN for either the active or passive (default) MLD mode. The VLAN setting overrides the global setting:

- **Active** – In active MLD mode, the device actively sends out MLD queries to identify IPv6 multicast groups on the network, and makes entries in the MLD table based on the group membership reports it receives from the network.
- **Passive** – In passive MLD mode, the device forwards reports to router ports that receive queries. MLD snooping in the passive mode does not send queries. However, it does forward queries to the entire VLAN.

To set the MLD mode for VLAN 20 to active, enter the following commands.

```
Brocade(config)#vlan 20
Brocade(config-vlan-20)#mld-snooping active
```

Syntax: [no] **mld-snooping active | passive**

The default mode is passive.

Disabling MLD snooping for the VLAN

When MLD snooping is enabled globally, you can disable it for a specific VLAN. For example, the following commands disable MLD snooping for VLAN 20. This setting overrides the global setting for VLAN 20.

```
Brocade(config)#vlan 20
Brocade(config-vlan-20)#mld-snooping disable-mld-snoop
```

Syntax: [no] mld-snooping disable-mld-snoop

Configuring the MLD version for the VLAN

You can specify the MLD version for a VLAN. For example, the following commands configure VLAN 20 to use MLDv2.

```
Brocade(config)#vlan 20
Brocade(config-vlan-20)#mld-snooping version 2
```

Syntax: [no] mld-snooping version 1 | 2

When no MLD version is specified, the globally-configured MLD version is used. If an MLD version is specified for individual ports, these ports use that version, instead of the version specified for the VLAN.

Configuring the MLD version for individual ports

You can specify the MLD version for individual ports in a VLAN. For example, the following commands configure ports 1/4, 1/5, 1/6 and 2/1 to use MLDv2. The other ports use the MLD version specified with the **mld-snooping version** command, or the globally configured MLD version.

```
Brocade(config)#vlan 20
Brocade(config-vlan-20)#mld-snooping port-version 2 ethe 2/1 ethe 1/4 to 1/6
```

Syntax: [no] mld-snooping port-version 1 | 2 ethernet <port-numbers>

Configuring static groups to the entire VLAN or to individual ports

NOTE

On FastIron X Series devices, you can configure MLD snooping static groups for individual ports in a VLAN, but not for the entire VLAN.

A snooping-enabled VLAN cannot forward multicast traffic to ports that do not receive MLD membership reports. To allow clients to send reports, you can configure a static group which applies to the entire VLAN, or to individual ports on the VLAN. The maximum number of supported static groups in a VLAN is 512, and the maximum number of supported static groups for individual ports in a VLAN is 256. The static group forwards packets to the static group ports even if they have no client membership reports. The static group for the entire VLAN is used in VLAN flooding because it uses fewer hardware resources than the static group for individual ports. Configure a static group for specific ports on VLAN 20 using commands similar to the following.

```
Brocade(config)#vlan 20
Brocade(config-vlan-20)#mld-snooping static-group ff05::100 count 2 ethe 1/3 ethe
1/5 to 1/7
Brocade(config-vlan-20)#mld-snooping static-group ff10::200
```

Syntax: [no] mld-snooping static-group <ipv6-address> [count <num>] [<port-numbers>]

The **ipv6-address** parameter is the IPv6 address of the multicast group.

The **count** is optional, which allows a contiguous range of groups. Omitting the count <num> is equivalent to the count being 1.

Except on FastIron X Series devices, if there are no port-numbers, the static groups apply to the entire VLAN.

Configuring static router ports

All multicast control and data packets are forwarded to router ports that receive queries. Although router ports are learned, you can configure static router ports to force multicast traffic to specific ports, even though these ports never receive queries. To configure static router ports, enter commands such as the following.

```
Brocade(config)#vlan 70
Brocade(config-vlan-70)#mld-snooping router-port e 1/4 to 1/5 e 1/8
```

Syntax: [no] mld-snooping router-port ethernet <port-numbers>

Disabling static group proxy

A device with statically configured groups acts as a proxy and sends membership reports for its static groups when it receives general or group-specific queries. When a static group configuration is removed, the group is immediately deleted from the active group table. However, the device does not send leave messages to the querier. The querier should age out the group. The proxy activity can be disabled (the default is enabled).

Example

```
Brocade(config)#vlan 20
Brocade(config-vlan-20)#mld-snooping proxy-off
```

Syntax: [no] mld-snooping proxy-off

By default, MLD snooping proxy is enabled.

Enabling MLDv2 membership tracking and fast leave for the VLAN

MLDv2 provides membership tracking and fast leave services to clients. In MLDv1, only one client per interface must respond to a router queries; leaving some clients invisible to the router, which makes it impossible for the device to track the membership of all clients in a group. In addition, when a client leaves the group, the device sends group-specific queries to the interface to see if other clients on that interface need the data stream of the client who is leaving. If no client responds, the device waits a few seconds before stopping the traffic. You can configure the wait time with the **ipv6 mld-snooping leave-wait-time** command. Refer to [“Modifying the wait time before stopping traffic when receiving a leave message”](#) on page 1618.

MLDv2 requires that every client respond to queries, allowing the device to track every client. When the tracking feature is enabled, the device immediately stops forwarding traffic to the interface if an MLDv2 client sends a leave message, and there is no other client. This feature requires the entire VLAN to be configured for MLDv2 and have no MLDv1 clients. If a client does not send a report during the specified group membership time (the default is 140 seconds), that client is removed from the tracking list.

Every group on a physical port keeps its own tracking record. However, it can track group membership only; it cannot track by (source, group). For example, Client A and Client B belong to group1 but each is receiving traffic from different sources. Client A receives a traffic stream from (source_1, group1) and Client B receives a traffic stream from (source_2, group1). The device waits for the configured **leave-wait-time** before it stops the traffic because the two clients are in the same group. If the clients are in different groups, the waiting period is ignored and traffic is stopped immediately.

To enable tracking and fast leave for VLAN 20, enter the following commands.

```
Brocade(config)#vlan 20
Brocade(config-vlan-20)#mld-snooping tracking
```

Syntax: [no] mld-snooping tracking

The membership tracking and fast leave features are supported for MLDv2 only. If a port or client is not configured for MLDv2, the **mld-snooping tracking** command is ignored.

Configuring fast leave for MLDv1

When a FESX or FSX device receives an MLDv1 leave message, it sends out multiple group-specific queries. If no other client replies within the waiting period, the device stops forwarding traffic to this port. Configuring fast-leave-v1 allows the device to stop forwarding traffic to a port immediately upon receiving a leave message. The device does not send group-specific queries. It is important that no snooping ports have multiple clients. When two devices connect, the querier device should not be configured for fast-leave-v1 because the port to the non-querier device could have multiple clients. The number of queries and the waiting period (in seconds) can be configured using the **ipv6 mld-snooping leave-wait-time** command. Refer to [“Modifying the wait time before stopping traffic when receiving a leave message”](#) on page 1618.

To configure fast leave for MLDv1, use commands such as the following.

```
Brocade(config)#vlan 20
Brocade(config-vlan-20)#mld-snooping fast-leave-v1
```

Syntax: [no] mld-snooping fast-leave-v1

Enabling fast convergence

In addition to periodically sending general queries, an active (querier) FESX or FSX device sends out general queries when it detects a new port. However, since it does not recognize the other device port-up event, the multicast traffic might still use the query-interval time to resume after a topology change. Configuring fast-convergence allows the device to listen to topology change events in Layer 2 (L2) protocols, such as spanning tree, and send general queries to shorten the convergence time.

If the L2 protocol is unable to detect a topology change, the fast-convergence feature may not work. For example, if the direct connection between two devices switches from one interface to another, the rapid spanning tree protocol (802.1w) considers this an optimization action, rather than a topology change. In this case, other devices will not receive topology change notifications and will be unable to send queries to speed up the convergence. The original spanning tree protocol does not recognize optimization actions, and fast-convergence works in all cases.

To enable fast-convergence, enter commands such as the following.

```
Brocade(config)#vlan 70
Brocade(config-vlan-70)#mld-snooping fast-convergence
```

Syntax: [no] mld-snooping fast-convergence

Displaying MLD snooping information

You can display the following MLD snooping information:

- MLD snooping error information
- Group and forwarding information for VLANs
- Information about MLD snooping mcache
- MLD memory pool usage
- Status of MLD traffic
- MLD information by VLAN

Displaying MLD snooping error information

To display information about possible MLD errors, enter the following command.

```
Brocade#show ipv6 mld-snooping error
snoop SW processed pkt: 173, up-time 160 sec
```

Syntax: show ipv6 mld-snooping error

The following table describes the output from the **show ipv6 mld-snooping error** command.

Field	Description
SW processed pkt	The number of IPv6 multicast packets processed by MLD snooping.
up-time	The MLD snooping up time.

Displaying MLD group information

To display MLD group information, enter the **ipv6 mld-snooping group** command.

```
Brocade#show ipv6 mld-snooping group
p-:physical, ST:static, QR:querier, EX:exclude, IN:include, Y:yes, N:no
VL1 : 263 grp, 263 grp-port, tracking_enabled
      group                                p-port ST QR life mode source
1      ff0e::ef00:a0e3                    1/7   N  Y  120 EX   0
2      ff01::1:f123:f567                  1/9   N  Y      IN   1
```

NOTE

In this example, an MLDv1 group is in EXCLUDE mode with a source of 0. The group excludes traffic from the 0 (zero) source list, which actually means that all traffic sources are included.

To display detailed MLD group information, enter the following command.

```
Brocade#show ipv6 mld-snooping group ff0e::ef00:a096 detail
Display group ff0e::ef00:a096 in all interfaces in details.
p-:physical, ST:static, QR:querier, EX:exclude, IN:include, Y:yes, N:no
VL1 : 1 grp, 1 grp-port, tracking_enabled
      group                                p-port ST QR life mode source
1      ff0e::ef00:a096                    1/7    N  Y  100 EX    0
      group: ff0e::ef00:a096, EX, permit 0 (source, life):
      life=100, deny 0:
```

If tracking and fast leave are enabled, you can display the list of clients for a particular group by entering the following command.

```
Brocade#show ipv6 mld-snooping group ff0e::ef00:a096 tracking
Display group ff0e::ef00:a096 in all interfaces with tracking enabled.
p-:physical, ST:static, QR:querier, EX:exclude, IN:include, Y:yes, N:no
VL1 : 1 grp, 1 grp-port, tracking_enabled
      group                                p-port ST QR life mode source
1      ff0e::ef00:a096                    1/7    N  Y   80 EX    0
      receive reports from 1 clients: (age)
      (fe80::1011:1213:1415 60)
```

Syntax: `show ipv6 mld-snooping group` [*<group-address>*] [**detail**] [**tracking**]

To receive a report for a specific multicast group, enter that group address for *<group-address>*.

Enter **detail** to display the source list of a specific VLAN.

Enter **tracking** for information on interfaces that are tracking-enabled.

The following table describes the information displayed by the **show ipv6 mld-snooping group** command.

Field.	Description
group	The address of the IPv6 group (destination IPv6 address).
p-port	The physical port on which the group membership was received.
ST	Yes indicates that the MLD group was configured as a static group; No means it was learned from reports.
QR	Yes means the port is a querier port; No means it is not. A port becomes a non-querier port when it receives a query from a source with a lower source IP address than the port.
life	The number of seconds the group can remain in EXCLUDE mode. An EXCLUDE mode changes to INCLUDE if it does not receive an IS_EX or TO_EX message during a specified period of time. The default is 140 seconds. There is no life displayed in INCLUDE mode.
mode	The current mode of the interface: INCLUDE or EXCLUDE. If the interface is in INCLUDE mode, it admits traffic only from the source list. If the interface is in EXCLUDE mode, it denies traffic from the source list and accepts the rest.

Field.	Description
source	Identifies the source list that will be included or excluded on the interface. An MLDv1 group is in EXCLUDE mode with a source of 0. The group excludes traffic from 0 (zero) source list, which actually means that all traffic sources are included.
group	If you requested a <i>detailed</i> report, the following information is displayed: <ul style="list-style-type: none"> • The multicast group address • The mode of the group • Sources from which traffic will be admitted (INCLUDE) or denied (EXCLUDE) on the interface. • The life of each source list. If you requested a <i>tracking/fast leave</i> report, the clients from which reports were received are identified.

Displaying MLD snooping mcache information

The MLD snooping mcache contains multicast forwarding information for VLANs. To display information in the multicast forwarding mcache, enter the **ipv6 mld-snooping mcache** command.

```
Brocade#show ipv6 mld-snooping mcache
Example: (S G) cnt=: (S G) are the lowest 32 bits, cnt: SW proc. count
        OIF: 1/22 TR(1/32,1/33), TR is trunk, 1/32 primary, 1/33 output
vlan 1, has 2 cache
1      (abcd:ef50 0:100), cnt=121
        OIF: 1/11 1/9
        age=0s up-time=120s vidx=4130 (ref-cnt=1)
2      (abcd:ef50 0:101), cnt=0
        OIF: entire vlan
        age=0s up-time=0s vidx=8191 (ref-cnt=1)
vlan 70, has 0 cache
```

Syntax: show ipv6 mld-snooping mcache

The following table describes the output from the **ipv6 mld-snooping mcache** command.

Field	Description
(abcd:ef50 0:100):	The lowest 32 bits of source and group. It is displayed in XXXX:XXXX hex format. Here XXXX is a 16-bit hex number.
cnt	The number of packets processed in software.
OIF	Output interfaces. <i>Entire vlan</i> means that static groups apply to the entire VLAN.
age	The mcache age in seconds. The mcache is reset to 0 if traffic continues to arrive, otherwise it is aged out when it reaches the time defined by ipv6 mld-snooping mcache-age .
uptime	The up time of this mcache in seconds.
vidx	The vidx is shared among mcache using the same output interfaces. The vidx specifies the output port list, which shows the index. Valid range is from 4096 to 8191.
ref-cnt	The number of mcache using this vidx.

Displaying software resource usage for VLANs

To display information about the software resources used, enter the following command.

```
Brocade#show ipv6 mld-snooping resource
          alloc in-use  avail get-fail    limit  get-mem  size init
mld group      512     9   503         0   32000    272   28  256
mld phy port   1024    16  1008         0  200000    279   21 1024
snoop group hash  512     9   503         0   59392    272   20  256
... Entries deleted
total pool memory 194432 bytes
has total 1 forwarding hash
Available vidx: 4061
```

Syntax: show ipv6 mld-snooping resource

The following table describes the output from the show **ipv6 mld-snooping resource** command.

This field...	Displays...
alloc	The allocated number of units.
in-use	The number of units which are currently used.
avail	The number of available units.
get-fail	The number of resource failures. NOTE: It is important to pay close attention to this field.
limit	The upper limit of this expandable field. The MLD group limit is configured using the system-max mld-max-group-addr command. The snoop mcache entry limit is configured using the system-max mld-snoop-mcache command.
get-mem	The current memory allocation. This number should continue to increase.
size	The size of a unit (in bytes).
init	The initial allocated amount of memory. NOTE: This number can be increased. (More memory can be allocated if necessary.)
Available vidx	The output interface (OIF) port mask used by mcache. The entire device has a maximum of 4096 vidx. Different mcaches with the same OIF share the same vidx. If vidx is not available, the stream cannot be hardware-switched.

Displaying status of MLD snooping traffic

To display status information for MLD snooping traffic, enter the **ipv6 mld-snooping traffic** command.

```
Brocade#show ipv6 mld-snooping traffic
MLD snooping: Total Recv: 32208, Xmit: 166
Q: query, Qry: general Q, G-Qry: group Q, GSQry: group-source Q, Mbr: member
Recv      QryV1      QryV2      G-Qry      GSQry      MbrV1      MbrV2      Leave
VL1        0          0          0          0        31744        208        256
VL70       0          0          0          0          0          0          0
Recv      IsIN      IsEX      ToIN      ToEX      ALLOW      BLOCK      Pkt-Err
VL1       1473      31784      0          1          1          7          0
VL70      0          0          0          0          0          0          0
Send      QryV1      QryV2      G-Qry      GSQry      MbrV1      MbrV2
VL1        0          0         166         0          0          0
VL70       0          0          0          0          0          0
```

Syntax: show ipv6 mld-snooping traffic

The following table describes the information displayed by the **show ipv6 mld-snooping traffic** command.

Field	Description
Q	Query
Qry	General Query
QryV1	Number of general MLDv1 queries received or sent.
QryV2	Number of general MLDv2 snooping queries received or sent.
G-Qry	Number of group specific queries received or sent.
GSQry	Number of group source specific queries received or sent.
MBR	The membership report.
MbrV1	The MLDv1 membership report.
MbrV2	The MLDv2 membership report.
IsIN	Number of source addresses that were included in the traffic.
IsEX	Number of source addresses that were excluded in the traffic.
ToIN	Number of times the interface mode changed from EXCLUDE to INCLUDE.
ToEX	Number of times the interface mode changed from INCLUDE to EXCLUDE.
ALLO	Number of times additional source addresses were allowed on the interface.
BLK	Number of times sources were removed from an interface.
Pkt-Err	Number of packets having errors such as checksum errors.

Displaying MLD snooping information by VLAN

You can display MLD snooping information for all VLANs or for a specific VLAN. For example, to display MLD snooping information for VLAN 70, enter the **ipv6 mld-snooping vlan <num>** command.

```
Brocade#show ipv6 mld-snooping vlan 70
version=1, query-t=60, group-aging-t=140, max-resp-t=3, other-qr-present-t=123
VL70: cfg V2, vlan cfg passive, 2 grp, 0 (SG) cache, rtr ports,
  router ports: 1/36(120) fe80::2e0:52ff:fe00:9900,
  1/26 has 2 grp, non-QR (passive), cfg V1
  1/26 has 2 grp, non-QR (passive), cfg V1
  group: ff10:1234::5679, life = 100
  group: ff10:1234::5678, life = 100
  1/35 has 0 grp, non-QR (QR=fe80::2e0:52ff:fe00:9900, age=20), dft V2 trunk
```

Syntax: **show ipv6 mld-snooping vlan** [**<vlan-id>**]

If you do not specify a **vlan-id**, information for all VLANs is displayed.

The following table describes information displayed by the **show ipv6 mld-snooping vlan** command.

Field	Description
version	The MLD version number.
query-t	How often a querier sends a general query on the interface.
group-aging-t	Number of seconds membership groups can be members of this group before aging out.
rtr-port	The router ports which are the ports receiving queries. The display <code>router ports: 1/36(120) fe80::2e0:52ff:fe00:9900</code> means port 1/36 has a querier with fe80::2e0:52ff:fe00:9900 as the link-local address, and the remaining life is 120 seconds.
max-resp-t	The maximum number of seconds a client can wait before it replies to the query.
non-QR	Indicates that the port is a non-querier.
QR	Indicates that the port is a querier.

Clearing MLD snooping counters and mcache

The clear commands for MLD snooping should only be used in troubleshooting situations or when recovering from error conditions.

Clearing MLD counters on all VLANs

To clear MLD snooping error and traffic counters on all VLANs, enter the **ipv6 mld-snooping counters** command.

```
Brocade#clear ipv6 mld-snooping counters
```

Syntax: **clear ipv6 mld-snooping counters**

Clearing the mcache on all VLANs

To clear the mcache on all VLANs, enter the **clear ipv6 mld-snooping mcache** command.

```
Brocade#clear ipv6 mld-snooping mcache
```

Syntax: `clear ipv6 mld-snooping mcache`

Clearing the mcache on a specific VLAN

To clear the mcache on a specific VLAN, enter the **clear ipv6 mld-snooping vlan <num> mcache** command.

```
Brocade#clear ipv6 mld-snooping vlan 10 mcache
```

Syntax: `clear ipv6 mld-snooping vlan <vlan-id> mcache`

The <vlan-id> parameter specifies the specific VLAN from which to clear the cache.

Clearing traffic counters on a specific VLAN

To clear the traffic counters on a specific VLAN, enter the **clear ipv6 mld-snooping vlan <num> traffic** command.

```
Brocade#clear ipv6 mld-snooping vlan 10 traffic
```

Syntax: `clear ipv6 mld-snooping vlan <vlan-id> traffic`

The <vlan-id> parameter specifies the specific VLAN from which to clear the traffic counters.

MLD snooping configuration

MLD Snooping on FastIron WS and Brocade FCX and ICX Switches

[Table 274](#) lists the individual Brocade FastIron switches and the Multicast Listening Discovery (MLD) snooping features they support. These features are supported in the Layer 2, base Layer 3, edge Layer 3, and full Layer 3 software images.

TABLE 274 Supported MLD snooping features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
MLD V1/V2 snooping (global and local)	This chapter describes MLD snooping on the FWS and FCX. For information about MLD snooping on other FastIron devices, see Chapter 37, “MLD Snooping on FastIron X Series Switches” .	Yes	Yes	Yes	Yes
MLD fast leave for V1		Yes	Yes	Yes	Yes
MLD tracking and fast leave for V2		Yes	Yes	Yes	Yes
Static MLD and IGMP groups with support for proxy		Yes	Yes	Yes	Yes

MLD snooping overview

The default method a device uses to process an IPv6 multicast packet is to broadcast it to all ports except the incoming port of a VLAN. Packets are flooded by hardware without going to CPU, which may result in some clients receiving unwanted traffic.

Multicast Learning Discovery (MLD) Snooping provides multicast containment by forwarding traffic only to those clients that have MLD receivers for a specific multicast group (destination address). The device maintains the MLD group membership information by processing MLD reports and generating messages so traffic can be forwarded to ports receiving MLD reports. This is analogous to IGMP Snooping on the Brocade Layer3 switches.

An IPv6 multicast address is a destination address in the range of FF00::/8. A limited number of multicast addresses are reserved. Since packets destined for the reserved addresses may require VLAN flooding, these devices do not snoop in the FFOX::000X range (where X is from 0 to F). Data packets destined to these addresses are flooded to the entire VLAN by hardware, and mirrored to CPU. Multicast data packets destined to addresses outside the FFOX::000X range are snooped. A client must send MLD reports in order to receive traffic. If an application outside the FFOX::000X range requires VLAN flooding, you must configure a static group for the entire VLAN.

An MLD device periodically broadcasts general queries, and sends group queries upon receiving a leave message to ensure no other clients at the same port still want this specific traffic before removing it. MLDv1 allows clients to specify which group (destination IPv6 address) on which to receive traffic. (MLDv1 cannot choose the source of the traffic.) MLDv2 deals with source-specific multicasts, adding the capability for clients to INCLUDE or EXCLUDE specific traffic sources. An MLDv2 device's port state can either be in INCLUDE or EXCLUDE mode. There are different types of group records for client reports.

The interfaces respond to general queries by sending a membership report containing one or more of the following records associated with a specific group:

- Current-state record - Indicates the sources from which the interface wants to receive or not receive traffic. This record contains the source addresses of the interfaces and whether or not traffic will be included (IS_IN) or excluded (IS_EX) from that source address.
- Filter-mode-change record - If the interface changes its current state from IS_IN to IS_EX, a TO_EX record is included in the membership report. Likewise, if an interface current state changes from IS_EX to IS_IN, a TO_IN record appears in the membership report.
- MLDv1 leave report - Equivalent to a TO_IN (empty) record in MLDv2. This record means that no traffic from this group will be received regardless of the source.
- An MLDv1 group report - Equivalent to an IS_EX (empty) record in MLDv2. This record means that all traffic from this group will be received regardless of source.
- Source-list-change record - If the interface wants to add or remove traffic sources from its membership report, the report can include an ALLOW record, which contains a list of new sources from which the interface wishes to receive traffic. The report can also contain a BLOCK record, which lists current traffic sources from which the interface wants to stop receiving traffic.

MLD protocols provide a way for clients and a device to exchange messages, and allow the device to build a database indicating which port wants what traffic. Since the MLD protocols do not specify forwarding methods, MLD Snooping or multicast protocols such as IPv6 PIM-Sparse Mode (PIM SM) are required to handle packet forwarding. PIM SM can route multicast packets within and outside a VLAN, while MLD Snooping can switch packets only within a VLAN. These devices do not support PIM-SM routing.

If a VLAN is not MLD Snooping-enabled, it floods IPv6 multicast data and control packets to the entire VLAN in hardware. When snooping is enabled, MLD packets are trapped to the CPU. Data packets are mirrored to the CPU and VLAN flooded. The CPU then installs hardware resources so subsequent data packets can be hardware-switched to desired ports without going through the CPU. If there is no client report, the hardware resource drops the data stream. The hardware can either match group addresses only (* G), or both source and group (S G) addresses in the data stream. If MLDv2 is configured in any port of a VLAN, the VLAN uses an (S G) match, otherwise it uses (* G). Because the hardware can match only the lowest 32 bits of a 128 bit IPv6 address, the output interfaces (OIF) of a hardware resource are the superset of the OIF of all data streams sharing the same lowest 32 bits. For example, if groups ff10::1234:5678:abcd and ff20::5678:abcd share the same hardware resource, then the OIF of the hardware matching (* 5678:abcd) is the superset of these two groups.

Stackable devices allocate 16K of hardware resources for MAC learning, IGMP, and MLD snooping. If a data packet does not match any of these resources, it might be sent to the CPU, increasing the CPU burden. This can happen if the device runs out of hardware resources, or is unable to install a resource for a specific matching address due to a hashing collision. Because the hardware hashes addresses into 16K entries, some addresses may be hashed into the same entry. If the collision number in an entry is more than the hardware chain length, the resource cannot be installed. The chain length can be configured using the **hash-chain-length** command, as follows.

```
Brocade(config)#hash-chain-length 8
```

Syntax: [no] **hash-chain-length** <num>

The `<num>` parameter range is 4 to 32, in multiples of 4. If the input value is not a multiple of 4, then it will be changed to the multiple of 4 lower than the input value (e.g. 11 will be changed to 8). The default hash chain length is 4. A chain length of more than 4 may affect line rate switching.

NOTE

For this command to take effect, you must save the configuration and reload the switch.

The hardware resource limit applies only to snooping-enabled VLANs. In VLANs where snooping is not enabled, multicast streams are switched in hardware without using any pre-installed resources.

The Brocade device supports up to 32K of MLD groups. They are produced by client membership reports.

Configuration notes for MLD snooping

- Servers (traffic sources) are not required to send MLD memberships.
- The default MLD version is V1.
- Hardware resources are installed only when there is data traffic. If a VLAN is configured for MLDv2, the hardware matches (S G), otherwise it matches (* G).
- You can configure the maximum number of groups and hardware-switched data streams.
- The device supports static groups applying to the entire VLAN, or to specific ports. The device acts as a proxy to send MLD reports for the static groups when receiving queries.
- A user can configure static router ports, forcing all multicast traffic to be sent to these ports.
- All devices support fast leave for MLDv1, which stops traffic immediately to any port that has received a leave message.
- All devices support tracking and fast leave for MLDv2, which tracks all MLDv2 clients. If the only client on a port leaves, traffic is stopped immediately.
- An MLD device can be configured as a querier (active) or non-querier (passive). Queriers send queries. Non-queriers listen for queries and forward them to the entire VLAN.
- Every VLAN can be independently configured as a querier or a non-querier.
- A VLAN that has a connection to an IPv6 PIM-enabled port on another router should be configured as a non-querier. When multiple snooping devices connect together and there is no connection to IPv6 PIM ports, only one device should be configured as the querier. If multiple devices are configured as active, only one will continue to send queries after the devices have exchanged queries. Refer to [“Configuring queriers and non-queriers on MLD snooping-enabled devices”](#) on page 1634.
- An MLD device can be configured to rate-limit the forwarding of MLDv1 membership reports to queriers.
- Because these devices use an IPv6 link-local address as the source address when sending queries, no global address is required.

The MLD implementation allows snooping on some VLANs or on all VLANs. MLD can be enabled or disabled independently for each VLAN. In addition, individual ports of a VLAN can be configured as MSLv1 and MLDv2. In general, global configuration commands such as **ipv6 mld-snooping...** apply to all VLANs except those with a local **mld-snooping..** configuration, which supersedes the global configuration. Configuring the version on a port or a VLAN only affects the device sent query version. The device always processes all versions of client reports regardless of the version configured.

MLD Snooping requires hardware resources. If the device has insufficient resources, the data stream without a resource is mirrored to the CPU in addition to being VLAN flooded, which can cause high CPU usage. To avoid this situation, Brocade recommends that you avoid enabling snooping globally unless necessary.

When any port of a VLAN is configured for MLDv2, the VLAN matches both source and group (S G) in hardware switching. If no port is configured for MLDv2, the VLAN matches group only (* G). Matching (S G) requires more hardware resources than (* G) when there are multiple servers sharing the same group. For example, two data streams from different sources to the same group require two (S G) entries in MLDv2, compared to only one (* G) in MLDv1. Brocade recommends that you use MLDv2 only in a source-specific application. Because each VLAN can be configured for the version independently, some VLANs might match (* G) while others match (S G).

To receive data traffic, MLD Snooping requires clients to send membership reports. If a client does not send reports, you must configure a static group to force traffic to client ports. The static group can either apply to some ports or to the entire VLAN.

Configuring queriers and non-queriers on MLD snooping-enabled devices

An MLD Snooping-enabled device can be configured as a querier (active) or non-querier (passive). An MLD querier sends queries; a non-querier listens for MLD queries and forwards them to the entire VLAN. VLANs can be independently configured as queriers or non-queriers. If a VLAN has a connection to an IPv6 PIM-enabled port on another router, the VLAN should be configured as a non-querier. When multiple MLD snooping devices are connected together, and there is no connection to an IPv6 PIM-enabled port, one of the devices should be configured as a querier. If multiple devices are configured as queriers, after multiple devices exchange queries, then all devices except the winner (the device with the lowest address) stop sending queries. Although the system works when multiple devices are configured as queriers, Brocade recommends that only one device, preferably the one with the traffic source, is configured as the querier.

Because non-queriers always forward multicast data traffic and MLD messages to router ports which receive MLD queries or IPv6 PIM hellos, Brocade recommends that you configure the devices with the data traffic source (server) as queriers. If a server is attached to a non-querier, the non-querier always forwards traffic to the querier regardless of whether or not there are clients on the querier.

NOTE

In a topology with one or more connected devices, at least one device must be running PIM, or configured as active. Otherwise, no devices can send queries, and traffic cannot be forwarded to clients.

MLD snooping configuration on VLANs

You can configure MLD snooping on some VLANs or all VLANs. Each VLAN can be independently enabled or disabled for MLD snooping, or can be configured with MLDv1 or MLDv2. In general, the **ipv6 mld-snooping...** commands apply globally to all VLANs except those configured with **VLAN-specific mld-snooping...** commands. **VLAN-specific mld-snooping** commands supersede **global ipv6 mld-snooping** commands.

MLD snooping using MLDv1 with MLDv2

MLD snooping can be configured as MLDv1 or MLDv2 on individual ports on a VLAN. An interface or router sends queries and reports that include the MLD version with which it has been configured. The version configuration applies only to the sending of queries. The snooping device recognizes and processes MLDv1 and MLDv2 packets regardless of the version configured.

NOTE

To avoid version deadlock, when an interface receives a report with a lower version than that for which it has been configured, the interface does **not** automatically downgrade the running MLD version.

MLD snooping configuration

Configuring MLD Snooping on Stackable devices consists of the following global and VLAN-specific tasks.

Global tasks for MLD Snooping

- Configuring hardware and software resource limits
- Disabling transmission and receipt of MLD packets on a port
- Configuring the MLD mode: active or passive (must be enabled for MLD Snooping)
- Modifying the age interval
- Specifying the interval for query messages (active MLD mode only)
- Specifying the global MLD version
- Enabling and disabling report control (rate limiting)
- Modifying the leave-wait time
- Modifying the mcache age interval
- Disabling error and warning messages

VLAN-specific tasks for MLD Snooping

- Configuring the MLD mode for the VLAN: active or passive
- Enabling or disabling MLD Snooping for the VLAN
- Configuring the MLD version for the VLAN
- Configuring the MLD version for individual ports
- Configuring static groups to the entire VLAN or some ports
- Configuring static router ports
- Enabling client tracking and the fast leave feature for MLDv2
- Configuring fast leave for MLDv1
- Configuring fast-convergence

Configuring the hardware and software resource limits

The system supports up to 8K of hardware-switched multicast streams. The configurable range is from 256 to 8192 and the default is 512. However, for ICX 6430, the range is from 256 to 1024, and the default is 256, while for ICX 6450, the range is from 256 to 8192 with the default as 512. Enter the **system-max mld-snoop-mcache** *<num>* command to define the maximum number of MLD Snooping cache entries.

```
Brocade(config)#system-max mld-snoop-mcache 8000
```

Syntax: [no] **system-max mld-snoop-mcache** *<num>*

The system supports up to 32K of groups. The configurable range is 256 to 32768 and the default is 8192. The configured number is the upper limit of an expandable database. Client memberships exceeding the group limits are not processed.

Disabling transmission and receipt of MLD packets on a port

When a VLAN is snooping-enabled, all MLD packets are trapped to the CPU without hardware VLAN flooding. The CPU can block MLD packets to and from a multicast-disabled port, and will not add that port to the output interfaces or hardware resources, which prevents the disabled port from receiving multicast traffic. However, if static groups to the entire VLAN are defined, the traffic for these groups is flooded to the entire VLAN, including to the disabled ports. Since the hardware cannot block traffic from disabled ports, hardware traffic is switched in the same way as traffic from enabled ports.

NOTE

This command has no effect on a VLAN that is not snooping-enabled because all multicast traffic is VLAN flooded.

```
Brocade(config)#interface ethernet 0/1/3
Brocade(config-if-e1000-0/1/3)#ipv6-multicast-disable
```

Syntax: [no] **ipv6-multicast-disable**

Configuring the global MLD mode

You can configure a device for either active or passive (default) MLD mode. If you specify an MLD mode for a VLAN, the MLD mode overrides the global setting:

- **Active** – In active MLD mode, the device actively sends out MLD queries to identify IPv6 multicast groups on the network, and makes entries in the MLD table based on the group membership reports it receives from the network.
- **Passive** – In passive MLD mode, the device forwards reports to the router ports which receive queries. MLD Snooping in passive mode does not send queries, but does forward queries to the entire VLAN.

To globally set the MLD mode to active for the device, enter the **ipv6 mld-snooping active** command.

```
Brocade(config)#ipv6 mld-snooping active
```

Syntax: [no] **ipv6 mld-snooping** [active | passive]

Omitting both the **active** and **passive** keywords is the same as entering **ipv6 mld-snooping passive**.

Modifying the age interval

When the device receives a group membership report, it makes an entry in the MLD group table for the group in the report. The age interval specifies how long the entry can remain in the table without the device receiving another group membership report. When multiple devices connect together, all devices should be configured with the same age interval. The age interval should be at least twice that of the query interval, so that missing one report will not stop traffic. For a non-querier, the query interval should equal that of the querier.

To modify the age interval, enter the **ipv6 mld-snooping age-interval <num>** command.

```
Brocade(config)#ipv6 mld-snooping age-interval 280
```

Syntax: [no] **ipv6 mld-snooping age-interval <interval>**

The **<interval>** parameter specifies the aging time. You can specify a value from 20 – 7200 seconds. The default is 140 seconds.

Modifying the query interval (Active MLD snooping mode only)

If the MLD mode is set to active, you can modify the query interval, which specifies how often the device sends group membership queries. When multiple queriers connect together, all queriers should be configured with the same interval.

To modify the query interval, enter the **ipv6 mld-snooping query-interval <num>** command.

```
Brocade(config)#ipv6 mld-snooping query-interval 120
```

Syntax: [no] **ipv6 mld-snooping query-interval <interval>**

The **<interval>** parameter specifies the interval between queries. You can specify a value from 10 – 3600 seconds. The default is 60 seconds.

Configuring the global MLD version

The default version is MLDv1. You can specify the global MLD version on the device as either MLDv1 or MLDv2. For example, the **ipv6 mld-snooping version <num>** command configures the device to use MLDv2.

```
Brocade(config)#ipv6 mld-snooping version 2
```

Syntax: [no] **ipv6 mld-snooping version 1 | 2**

You can also specify the MLD version for individual VLANs, or individual ports within VLANs. If no MLD version is specified for a VLAN, then the globally configured MLD version is used. If an MLD version is specified for individual ports in a VLAN, those ports use that version instead of the version specified for the VLAN or the globally specified version. The default is MLDv1.

Configuring report control

When a device is in passive mode, it forwards reports and leave messages from clients to the upstream router ports that are receiving queries.

You can configure report control to rate-limit report forwarding for the same group to no more than once per 10 seconds. This rate limiting does not apply to the first report answering a group-specific query.

NOTE

This feature applies to MLDv1 only. The leave messages are not rate limited.

MLDv1 membership reports for the same group from different clients are considered to be the same, and are rate-limited. This alleviates the report storm caused by multiple clients answering the upstream router query. To enable report-control, use the **ipv6 mld-snooping report-control** command.

```
Brocade(config)#ipv6 mld-snooping report-control
```

Syntax: [no] ipv6 mld-snooping report-control

Modifying the wait time before stopping traffic when receiving a leave message

You can define the wait time before stopping traffic to a port when the device receives a leave message for that port. The device sends group-specific queries once per second to determine if any client on the same port still needs the group. The value range is from 1 to 5, and the default is 2. Due to the internal timer accuracy, the actual wait time is between n and $(n+1)$ seconds, where n is the configured value.

```
Brocade(config)#ipv6 mld-snooping leave-wait-time 1
```

Syntax: [no] ipv6 mld-snooping leave-wait-time <num>

Modifying the multicast cache (mcache) aging time

You can set the time for an mcache to age out when it does not receive traffic. The traffic is hardware-switched. One minute before an mcache is aged out, the device mirrors a packet of the mcache to the CPU to reset the age. If no data traffic arrives within one minute, the mcache is deleted. If you configure a lower value, the resource consumed by idle streams is quickly removed, but packets are mirrored to the CPU more frequently. Configure a higher value only when data streams are arriving consistently. The range is 60 to 3600 seconds, and the default is 60 seconds.

```
Brocade(config)#ipv6 mld-snooping mcache-age 180
```

Syntax: [no] ipv6 mld-snooping mcache-age <num>

Disabling error and warning messages

The device prints error or warning messages when it runs out of software resources or when it receives packets with the wrong checksum or groups. These messages are rate limited. You can turn off these messages by entering the **ipv6 mld-snooping verbose-off** command.

```
Brocade(config)#ipv6 mld-snooping verbose-off
```

Syntax: [no] ipv6 mld-snooping verbose-off

Configuring the MLD mode for a VLAN

You can configure a VLAN for either the active or passive (default) MLD mode. The VLAN setting overrides the global setting:

- **Active** – In active MLD mode, a device actively sends out MLD queries to identify IPv6 multicast groups on the network, and makes entries in the MLD table based on the group membership reports it receives from the network.
- **Passive** – In passive MLD mode, the device forwards reports to router ports which receive queries. MLD snooping in the passive mode does not send queries. However, it does forward queries to the entire VLAN.

To set the MLD mode for VLAN 20 to active, enter the following commands.

```
Brocade(config)#vlan 20
Brocade(config-vlan-20)#mld-snooping active
```

Syntax: [no] mld-snooping active | passive

Disabling MLD snooping for the VLAN

When MLD snooping is enabled globally, you can disable it for a specific VLAN. For example, the following commands disable MLD snooping for VLAN 20. This setting overrides the global setting for VLAN 20.

```
Brocade(config)#vlan 20
Brocade(config-vlan-20)#mld-snooping disable-mld-snoop
```

Syntax: [no] mld-snooping disable-mld-snoop

Configuring the MLD version for the VLAN

You can specify the MLD version for a VLAN. For example, the following commands configure VLAN 20 to use MLDv2.

```
Brocade(config)#vlan 20
Brocade(config-vlan-20)#mld-snooping version 2
```

Syntax: [no] mld-snooping version 1 | 2

When no MLD version is specified, the globally-configured MLD version is used. If an MLD version is specified for individual ports, these ports use that version, instead of the version specified for the VLAN.

Configuring the MLD version for individual ports

You can specify the MLD version for individual ports in a VLAN. For example, the following commands configure ports 0/1/4, 0/1/5, 0/1/6 and 0/2/1 to use MLDv2. The other ports use the MLD version specified with the **mld-snooping version** command, or the globally configured MLD version.

```
Brocade(config)#vlan 20
Brocade(config-vlan-20)#mld-snooping port-version 2 ethe 0/2/1 ethe 0/1/4 to
0/1/6
```

Syntax: [no]mld-snooping port-version 1 | 2 ethernet <stack-unit/slot/port> [ethernet <stack-unit/slot/port>] [to ethernet <stack-unit/slot/port>]

Configuring static groups to the entire VLAN or to individual ports

A snooping-enabled VLAN cannot forward multicast traffic to ports that do not receive MLD membership reports. To allow clients to send reports, you can configure a static group which applies to the entire VLAN, or to individual ports on the VLAN. The static group forwards packets to the static group ports even if they have no client membership reports. The static group for the entire VLAN is used in VLAN flooding because it uses fewer hardware resources than the static group for individual ports. Configure a static group for specific ports on VLAN 20 using commands similar to the following.

```
Brocade(config)#vlan 20
Brocade(config-vlan-20)#mld-snooping static-group ff05::100 count 2 ethe 0/1/3
ethe 0/1/5 to 0/1/7
Brocade(config-vlan-20)#mld-snooping static-group ff10::200
```

Syntax: [no] mld-snooping static-group <ipv6-address> [count <num>] [<stack-unit/slot/port>]

The **ipv6-address** parameter is the IPv6 address of the multicast group.

The **count** is optional, which allows a contiguous range of groups. Omitting the count <num> is equivalent to the count being 1.

If there are no <stack-unit/slot/port> numbers, the static groups apply to the entire VLAN.

Configuring static router ports

A device always forwards all multicast control and data packets to router ports that receive queries. Although router ports are learned, you can configure static router ports to force multicast traffic to specific ports, even though these ports never receive queries. To configure static router ports, enter commands such as the following.

```
Brocade(config)#vlan 70
Brocade(config-vlan-70)#mld-snooping router-port e 0/1/4 to 0/1/5 e 0/1/8
```

Syntax: [no] mld-snooping router-port <stack-unit/slot/port>

Turning off static group proxy

A device with static groups configured acts as a proxy and sends membership reports for its static groups when it receives general or group-specific queries. When a static group configuration is removed, the group is deleted from active group table immediately. However, the device does not send leave messages to the querier. The querier should age the group out. The proxy activity can be turned off (the default is on). For example.

```
Brocade(config)#vlan 20
Brocade(config-vlan-20)#mld-snooping proxy-off
```

Syntax: [no] mld-snooping proxy-off

Enabling MLDv2 membership tracking and fast leave for the VLAN

MLDv2 provides membership tracking and fast leave services to clients. In MLDv1, only one client per interface must respond to a router queries; leaving some clients invisible to the router, which makes it impossible for the device to track the membership of all clients in a group. In addition, when a client leaves the group, the device sends group-specific queries to the interface to see if other clients on that interface need the data stream of the client who is leaving. If no client responds, the device waits a few seconds before stopping the traffic. You can configure the wait time with the **ipv6 mld-snooping leave-wait-time** command.

MLDv2 requires that every client respond to queries, allowing the device is able to track every client. When the tracking feature is enabled, the device immediately stops forwarding traffic to the interface if an MLDv2 client sends a leave message, and there is no other client. This feature requires the entire VLAN to be configured for MLDv2 and have no MLDv1 clients. If a client does not send a report during the specified group membership time (the default is 140 seconds), that client is removed from the tracking list.

Every group on a physical port keeps its own tracking record. However, it can track group membership only; it cannot track by (source, group). For example, Client A and Client B belong to group1 but each is receiving traffic from different sources. Client A receives a traffic stream from (source_1, group1) and Client B receives a traffic stream from (source_2, group1). The device waits for the configured **leave-wait-time** before it stops the traffic because the two clients are in the same group. If the clients are in different groups, the waiting period is ignored and traffic is stopped immediately.

To enable tracking and fast leave for VLAN 20, enter the following commands.

```
Brocade(config)#vlan 20
Brocade(config-vlan-20)#mld-snooping tracking
```

Syntax: [no] mld-snooping tracking

The membership tracking and fast leave features are supported for MLDv2 only. If a port or client is not configured for MLDv2, the **mld-snooping tracking** command is ignored.

Configuring fast leave for MLDv1

When a device receives an MLDv1 leave message, it sends out multiple group-specific queries. If no other client replies within the waiting period, the device stops forwarding traffic to this port. Configuring fast-leave-v1 allows the device to stop forwarding traffic to a port immediately upon receiving a leave message. The device does not send group-specific queries. It is important that no snooping ports have multiple clients. When two devices connect, the querier device should not be configured for fast-leave-v1 because the port to the non-querier device could have multiple clients. The number of queries and the waiting period (in seconds) can be configured using the **ipv6 mld-snooping leave-wait-time** command. The default is 2 seconds. To configure fast leave for MLDv1, use commands such as the following.

```
Brocade(config)#vlan 20
Brocade(config-vlan-20)#mld-snooping fast-leave-v1
```

Syntax: [no] mld-snooping fast-leave-v1

Enabling fast convergence

In addition to periodically sending general queries, an active (querier) device sends out general queries when it detects a new port. However, since it does not recognize the other device port-up event, the multicast traffic might still use the query-interval time to resume after a topology change. Configuring fast-convergence allows the device to listen to topology change events in L2 protocols, such as spanning tree, and send general queries to shorten the convergence time.

If the L2 protocol is unable to detect a topology change, the fast-convergence feature may not work. For example, if the direct connection between two devices switches from one interface to another, the rapid spanning tree protocol (802.1w) considers this an optimization action, rather than a topology change. In this case, other devices will not receive topology change notifications and will be unable to send queries to speed up the convergence. The original spanning tree protocol does not recognize optimization actions, and fast-convergence works in all cases.

To enable fast-convergence, enter commands such as the following.

```
Brocade(config)#vlan 70
Brocade(config-vlan-70)#mld-snooping fast-convergence
```

Syntax: mld-snooping fast-convergence

Displaying MLD snooping information

You can display the following MLD Snooping information:

- MLD Snooping error information
- Information about VLANs
- Group and forwarding information for VLANs
- MLD memory pool usage
- Status of MLD traffic
- MLD information by VLAN

Displaying MLD snooping error information

To display information about possible MLD errors, enter commands such as the following.

```
Brocade#show ipv6 mld-snooping error
snoop SW processed pkt: 173, up-time 160 sec
```

Syntax: show ipv6 mld-snooping error

The following table describes the output from the **show ipv6 mld-snooping error** command.

Field	Description
SW processed pkt	The number of IPv6 multicast packets processed by MLD snooping.
up-time	The time since the MLD snooping last occurred is enabled.

Displaying MLD group information

To display MLD group information, enter the **show ipv6 mld-snooping group** command.

```
Brocade#show ipv6 mld-snooping group
p-:physical, ST:static, QR:querier, EX:exclude, IN:include, Y:yes, N:no
VL1 : 263 grp, 263 grp-port, tracking_enabled
      group                                p-port ST QR life mode source
1      ff0e::ef00:a0e3                    0/1/7  N  Y  120  EX   0
2      ff01::1:f123:f567                  0/1/9  N  Y      IN   1
```

NOTE

In this example, an MLDv1 group is in EXCLUDE mode with a source of 0. The group excludes traffic from the 0 (zero) source list, which actually means that all traffic sources are included.

To display detailed MLD group information, enter the **show ipv6 mld-snooping group detail** command.

```
Brocade#show ipv6 mld-snooping group ff0e::ef00:a096 detail
Display group ff0e::ef00:a096 in all interfaces in details.
p-:physical, ST:static, QR:querier, EX:exclude, IN:include, Y:yes, N:no
VL1 : 1 grp, 1 grp-port, tracking_enabled
      group                                p-port ST QR life mode source
1      ff0e::ef00:a096                    0/1/7  N  Y  100  EX   0
      group: ff0e::ef00:a096, EX, permit 0 (source, life):
      life=100, deny 0:
```

If tracking and fast leave are enabled, you can display the list of clients for a particular group by entering the **show ipv6 mld-snooping group tracking** command.

```
Brocade#show ipv6 mld-snooping group ff0e::ef00:a096 tracking
Display group ff0e::ef00:a096 in all interfaces with tracking enabled.
p-:physical, ST:static, QR:querier, EX:exclude, IN:include, Y:yes, N:no
VL1 : 1 grp, 1 grp-port, tracking_enabled
      group                                p-port ST QR life mode source
1      ff0e::ef00:a096                    0/1/7  N  Y   80  EX   0
      receive reports from 1 clients: (age)
      (fe80::1011:1213:1415 60)
```

Syntax: **show ipv6 mld-snooping group** [*<group-address>*] [**detail**] [**tracking**]

To receive a report for a specific multicast group, enter that group address for *<group-address>*.

Enter **detail** to display the source list of a specific VLAN.

Enter **tracking** for information on interfaces that are tracking-enabled.

The following table describes the information displayed by the **show ipv6 mld-snooping group** command.

Field	Description
group	The address of the IPv6 group (destination IPv6 address).
p-port	The physical port on which the group membership was received.
ST	Yes indicates that the MLD group was configured as a static group; No means it was learned from reports.

Field	Description
QR	Yes means the port is a querier port; No means it is not. A port becomes a non-querier port when it receives a query from a source with a lower source IP address than the port.
life	The number of seconds the group can remain in EXCLUDE mode. An EXCLUDE mode changes to INCLUDE if it does not receive an IS_EX or TO_EX message during a specified period of time. The default is 140 seconds. There is no <code>life</code> displayed in INCLUDE mode.
mode	The current mode of the interface: INCLUDE or EXCLUDE. If the interface is in INCLUDE mode, it admits traffic only from the source list. If the interface is in EXCLUDE mode, it denies traffic from the source list and accepts the rest.
source	Identifies the source list that will be included or excluded on the interface. An MLDv1 group is in EXCLUDE mode with a source of 0. The group excludes traffic from 0 (zero) source list, which actually means that all traffic sources are included.
group	If you requested a <i>detailed</i> report, the following information is displayed: <ul style="list-style-type: none"> • The multicast group address • The mode of the group • Sources from which traffic will be admitted (INCLUDE) or denied (EXCLUDE) on the interface. • The life of each source list. If you requested a <i>tracking/fast leave</i> report, the clients from which reports were received are identified.

Displaying MLD snooping mcache information

The MLD snooping mcache contains multicast forwarding information for VLANs. To display information in the multicast forwarding mcache, enter the **show ipv6 mld-snooping mcache** command.

```
Brocade#show ipv6 mld-snooping mcache
Example: (S G) cnt=: (S G) are the lowest 32 bits, cnt: SW proc. count
        OIF: 0/1/22 TR(0/1/32,0/1/33), TR is trunk, 0/1/32 primary, 0/1/33 output
vlan 1, has 2 cache
1  (abcd:ef50 0:100), cnt=121
   OIF: 0/1/11 0/1/9
   age=0s up-time=120m vidx=4130 (ref-cnt=1)
2  (abcd:ef50 0:101), cnt=0
   OIF: entire vlan
   age=0s up-time=0m vidx=8191 (ref-cnt=1)
vlan 70, has 0 cache
```

Syntax: show ipv6 mld-snooping mcache

The following table describes the output from the **ipv6 mld-snooping mcache** command.

Field	Description
(abcd:ef50 0:100):	The lowest 32 bits of source and group. It is displayed in XXXX:XXXX hex format. Here XXXX is a 16-bit hex number.
cnt	The number of packets processed in software. IPv6 packets are switched in software, causing this number to increase slowly.
OIF	Output interfaces. <i>Entire vlan</i> means that static groups apply to the entire VLAN.
age	The mcache age. The mcache is reset to 0 if traffic continues to arrive, otherwise it is aged out when it reaches the time defined by ipv6 mld-snooping mcache-age .

Field	Description
uptime	The up time of this mcache in minutes.
vidx	The vidx is shared among mcaches using the same output interfaces. The vidx specifies the output port list, which shows the index. Valid range is from 4096 to 8191.
ref-cnt	The number of mcaches using this vidx.

Displaying software resource usage for VLANs

To display information about the software resources used, enter the **show ipv6 mld-snooping resource** command.

```
Brocade#show ipv6 mld-snooping resource
          alloc in-use  avail get-fail    limit  get-mem  size init
mld group      512     9    503      0    32000    272    28  256
mld phy port   1024    16   1008      0   200000    279    21 1024
snoop group hash  512     9    503      0    59392    272    20  256
... Entries deleted
total pool memory 194432 bytes
has total 1 forwarding hash
Available vidx: 4061
```

Syntax: show ipv6 mld-snooping resource

The following table describes the output from the **show ipv6 mld-snooping resource** command.

Field	Description
alloc	The allocated number of units.
in-use	The number of units which are currently used.
avail	The number of available units.
get-fail	Displays the number of resource failures. NOTE: It is important to pay close attention to this field.
limit	The upper limit of this expandable field. The MLD group limit is configured using the system-max mld-max-group-addr command. The snoop mcache entry limit is configured using the system-max mld-snoop-mcache command.
get-mem	The number of memory allocation. This number should continue to increase.
size	The size of a unit (in bytes).
init	The initial allocated amount of memory. NOTE: This number can be increased. More memory can be allocated if necessary.
Available vidx	The output interface (OIF) port mask used by mcache. The entire device has a maximum of 4096 vidx. Different mcaches with the same OIF share the same vidx. If vidx is not available, the stream cannot be hardware-switched.

Displaying status of MLD snooping traffic

To display status information for MLD snooping traffic, enter the **show ipv6 mld-snooping traffic** command.

```
Brocade#show ipv6 mld-snooping traffic
MLD snooping: Total Recv: 32208, Xmit: 166
Q: query, Qry: general Q, G-Qry: group Q, GSQry: group-source Q, Mbr: member
Recv      QryV1      QryV2      G-Qry      GSQry      MbrV1      MbrV2      Leave
VL1        0          0          0          0          31744      208        256
VL70       0          0          0          0          0          0          0
Recv      IsIN      IsEX      ToIN      ToEX      ALLOW      BLOCK      Pkt-Err
VL1       1473      31784      0          1          1          7          0
VL70      0          0          0          0          0          0          0
Send      QryV1      QryV2      G-Qry      GSQry      MbrV1      MbrV2
VL1        0          0          166        0          0          0
VL70       0          0          0          0          0          0
```

Syntax: show ipv6 mld-snooping traffic

The following table describes the information displayed by the **show ipv6 mld-snooping traffic** command.

This field	Displays
Q	Query
Qry	General Query
QryV1	Number of general MLDv1 queries received or sent.
QryV2	Number of general MLDv2 snooping queries received or sent.
G-Qry	Number of group specific queries received or sent.
GSQry	Number of group source specific queries received or sent.
MBR	The membership report.
MbrV1	The MLDv1 membership report.
MbrV2	The MLDv2 membership report.
IsIN	Number of source addresses that were included in the traffic.
IsEX	Number of source addresses that were excluded in the traffic.
ToIN	Number of times the interface mode changed from EXCLUDE to INCLUDE.
ToEX	Number of times the interface mode changed from INCLUDE to EXCLUDE.
ALLO	Number of times additional source addresses were allowed on the interface.
BLK	Number of times sources were removed from an interface.
Pkt-Err	Number of packets having errors such as checksum errors.

Displaying MLD snooping information by VLAN

You can display MLD snooping information for all VLANs or for a specific VLAN. For example, to display MLD snooping information for VLAN 70, enter the following command.

```
Brocade#show ipv6 mld-snooping vlan 70
version=1, query-t=60, group-aging-t=140, max-resp-t=3, other-qr-present-t=123
VL70: cfg V2, vlan cfg passive, 2 grp, 0 (SG) cache, rtr ports,
      router ports: 0/1/36(120) fe80::2e0:52ff:fe00:9900,
      0/1/26 has 2 grp, non-QR (passive), cfg V1
      0/1/26 has 2 grp, non-QR (passive), cfg V1
      group: ff10:1234::5679, life = 100
      group: ff10:1234::5678, life = 100
      0/1/35 has 0 grp, non-QR (QR=fe80::2e0:52ff:fe00:9900, age=20), dft V2 trunk
```

Syntax: `show ipv6 mld-snooping vlan [<vlan-id>]`

If you do not specify a vlan-id, information for all VLANs is displayed.

The following table describes information displayed by the `show ipv6 mld-snooping vlan` command.

This field	Displays
version	The MLD version number.
query-t	How often a querier sends a general query on the interface.
group-aging-t	Number of seconds membership groups can be members of this group before aging out.
rtr-port	The router ports which are the ports receiving queries. The display <code>router ports: 0/1/36(120) fe80::2e0:52ff:fe00:9900</code> means port 0/1/36 has a querier with fe80::2e0:52ff:fe00:9900 as the link-local address, and the remaining life is 120 seconds.
max-resp-t	The maximum number of seconds a client can wait before it replies to the query.
non-QR	Indicates that the port is a non-querier.
QR	Indicates that the port is a querier.

Clear MLD snooping commands

The clear commands for MLD snooping should only be used in troubleshooting situations or when recovering from error conditions.

Clearing MLD counters on VLANs

To clear MLD Snooping error and traffic counters on all VLANs, enter the `clear ipv6 mld-snooping counters` command.

```
Brocade#clear ipv6 mld-snooping counters
```

Syntax: `clear ipv6 mld-snooping counters`

Clearing MLD mcache

To clear the mcache on all VLANs, enter the `clear ipv6 mld-snooping mcache` command.

```
Brocade#clear ipv6 mld-snooping mcache
```

Syntax: `clear ipv6 mld-snooping mcache`

Clearing mcache on a specific VLAN

To clear the mcache on a specific VLAN, enter the **clear ipv6 mld-snooping vlan <vlan-id> mcache** command.

```
Brocade#clear ipv6 mld-snooping vlan 10 mcache
```

Syntax: **clear ipv6 mld-snooping vlan <vlan-id> mcache**

The <vlan-id> parameter specifies the specific VLAN from which to clear the cache.

Clearing traffic on a specific VLAN

To clear the traffic counters on a specific VLAN, enter the **clear ipv6 mld-snooping vlan <vlan-id> traffic** command.

```
Brocade#clear ipv6 mld-snooping vlan 10 traffic
```

Syntax: **clear ipv6 mld-snooping vlan <vlan-id> traffic**

The <vlan-id> parameter specifies the specific VLAN from which to clear the traffic counters.

VRRP and VRRP-E

Table 275 lists the individual Brocade FastIron switches and the Virtual Router Redundancy Protocol (VRRP) and Virtual Router Redundancy Protocol Extended (VRRP-E) features they support.

NOTE

VRRP is supported in the base Layer 3, edge Layer 3, and full Layer 3 codes. VRRP support in the base Layer 3 and edge Layer 3 code is the same as in the full Layer 3 code. VRRP-E is supported with premium and ADV FastIron devices that are running the edge Layer 3 or full Layer 3 code.

TABLE 275 Supported VRRP and VRRP-E features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6450
Virtual Router Redundancy Protocol (VRRP)	Yes	Yes	Yes	Yes	Yes
VRRP timer scaling	Yes	Yes	Yes	Yes	Yes
VRRP Extended (VRRP-E)	Yes	Yes	Yes	Yes	Yes
IPv6 VRRP-E	Yes*	No	Yes	Yes	No
IPv6 VRRP v3	Yes*	No	Yes	Yes	No
VRRP-E slow start timer	Yes	Yes	Yes	Yes	Yes
VRRP-E timer scale	Yes	Yes	Yes	Yes	Yes
Forcing a Master router to abdicate to a standby router	Yes	No	Yes	Yes	Yes
VRRP-E Extension for Server Virtualization	Yes	No	No	No	No

* Refers to support for only IPv6 modules for these devices.

This chapter describes how to configure Brocade Layer 3 switches with the following router redundancy protocols:

- Virtual Router Redundancy Protocol (VRRP) – The standard router redundancy protocol described in RFC 2338. The FastIron devices support VRRP version 2 (v2) and VRRP version 3 (v3). VRRP v2 supports the IPv4 environment, and VRRP v3 supports the IPv6 environment.
- VRRP Extended (VRRP-E) – An enhanced version of VRRP that overcomes limitations in the standard protocol. The FastIron devices support VRRP-E v2 and VRRP-E v3. VRRP-E v2 supports the IPv4 environment, and VRRP-E v3 supports the IPv6 environment.

NOTE

VRRP and VRRP-E are separate protocols. You cannot use them together.

NOTE

You can use a Brocade Layer 3 switch configured for VRRP with another Brocade Layer 3 switch or a third-party router that is also configured for VRRP. However, you can use a Brocade Layer 3 switch configured for VRRP-E only with another Brocade Layer 3 switch that also is configured for VRRP-E.

NOTE

The maximum number of supported VRRP or VRRP-E router instances is 254 for IPv4 environments. The maximum number of supported VRRP or VRRP-E router instances is 128 for IPv6 environments.

For a summary of how these two router redundancy protocols differ, refer to [“Comparison of VRRP and VRRP-E”](#) on page 1658.

VRRP and VRRP-E overview

The following sections describe VRRP and VRRP-E. The protocols both provide redundant paths for IP addresses. However, the protocols differ in a few important ways. For clarity, each protocol is described separately.

VRRP overview

Virtual Router Redundancy Protocol (VRRP) provides redundancy to routers within a LAN. VRRP allows you to provide alternate router paths for a host without changing the IP address or MAC address by which the host knows its gateway. Consider the situation shown in [Figure 184](#).

FIGURE 184 Switch 1 is the Host1 default gateway but is a single point of failure

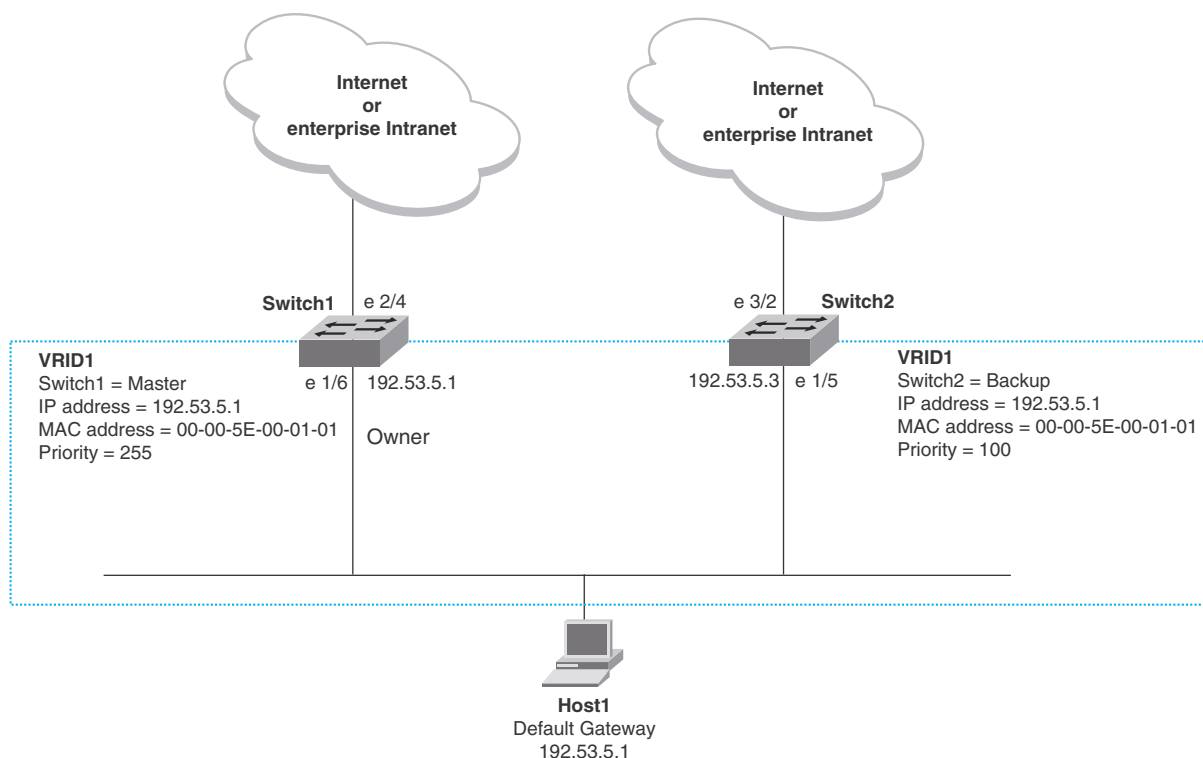

Switch 1 is the host default gateway out of the subnet. If this interface goes down, Host1 is cut off from the rest of the network. Switch 1 is thus a single point of failure for Host1's access to other networks.

If Switch 1 fails, you could configure Host1 to use Switch 2. Configuring one host with a different default gateway might not require too much extra administration. However, consider a more realistic network with dozens or even hundreds of hosts per subnet; reconfiguring the default gateways for all the hosts is impractical. It is much simpler to configure a VRRP virtual router on Switch 1 and Switch 2 to provide a redundant path for the hosts.

Figure 185 shows the same example network shown in Figure 184, but with a VRRP virtual router configured on Switch 1 and Switch 2.

FIGURE 185 Switch 1 and Switch 2 configured as VRRP virtual routers for redundant network access for Host1

The dashed box in Figure 185 represents a VRRP virtual router. When you configure a virtual router, one of the configuration parameters is the virtual router ID (VRID), which can be a number from 1 through 255. In this example, the VRID is 1.

NOTE

You can provide more redundancy by also configuring a second VRID with Switch 2 as the Owner and Switch 1 as the Backup. This type of configuration is sometimes called *Multigroup VRRP*.

Virtual router ID

A virtual router ID (VRID) consists of one Master router and one or more Backup routers. The Master router is the router that owns the IP addresses you associate with the VRID. For this reason, the Master router is sometimes called the “Owner”. Configure the VRID on the router that owns the default gateway interface. The other router in the VRID does not own the IP addresses associated with the VRID but provides the backup path if the Master router becomes unavailable.

Virtual router MAC address

Notice the MAC address associated with VRID1 in [Figure 185](#). The first five octets of the address are the standard MAC prefix for VRRP packets, as described in RFC 2338. The last octet is the VRID. The VRID number becomes the final octet in the virtual MAC address associated with the virtual router.

When you configure a VRID, the software automatically assigns its MAC address. When a VRID becomes active, the Master router broadcasts a gratuitous ARP request containing the virtual router MAC address for each IP address associated with the virtual router. In [Figure 185](#), Switch 1 sends a gratuitous ARP request with MAC address 00-00-5E-00-01-01 and IP address 192.53.5.1. Hosts use the virtual router MAC address in routed traffic they send to their default IP gateway (in this example, 192.53.5.1).

Virtual router IP address

VRRP does not use virtual IP addresses. Thus, there is no virtual IP address associated with a virtual router. Instead, you associate the virtual router with one or more real interface IP addresses configured on the router that owns the real IP addresses. In [Figure 185](#), the virtual router with VRID1 is associated with real IP address 192.53.5.1, which is configured on interface e1/6 on Switch 1. VRIDs are interface-level parameters, not system-level parameters, so the IP address you associate with the VRID must already be a real IP address configured on the Owner interface.

NOTE

You can associate a virtual router with a virtual interface. A virtual interface is a named set of physical interfaces.

When you configure the Backup router for the VRID, specify the same IP address as the one you specify on the Owner. This is the IP address used by the host as its default gateway. The IP address cannot also exist on the Backup router. The interface on which you configure the VRID on the Backup router must have an IP address in the same subnet.

NOTE

If you delete a real IP address used by a VRRP entry, the VRRP entry also is deleted automatically.

NOTE

When a Backup router takes over forwarding responsibilities from a failed Master router, the Backup forwards traffic addressed to the VRID MAC address, which the host believes is the MAC address of the router interface for its default gateway. However, the Backup router cannot reply to IP pings sent to the IP addresses associated with the VRID. Because the IP addresses are owned by the Owner, if the Owner is unavailable, the IP addresses are unavailable as packet destinations.

Master negotiation

The routers within a VRID use the VRRP priority values associated with each router to determine which router becomes the Master. When you configure the VRID on a router interface, you specify whether the router is the Owner of the IP addresses you plan to associate with the VRID or a Backup router. If you indicate that the router is the Owner of the IP addresses, the software automatically sets the router VRRP priority for the VRID to 255, the highest VRRP priority. The router with the highest priority becomes the Master.

Backup routers can have a priority from 3 through 254, which you assign when you configure the VRID on the Backup router interfaces. The default VRRP priority for Backup routers is 100.

Because the router that owns the IP addresses associated with the VRID always has the highest priority, when all the routers in the virtual router are operating normally, the negotiation process results in the Owner of the VRID IP addresses becoming the Master router. Thus, the VRRP negotiation results in the normal case, in which the host's path to the default route is to the router that owns the interface for that route.

Hello messages

Virtual routers use Hello messages for negotiation to determine the Master router. Virtual routers send Hello messages to IP Multicast address 224.0.0.18. The frequency with which the Master sends Hello messages is the Hello interval. Only the Master sends Hello messages. However, a Backup router uses the Hello interval you configure for the Backup router if it becomes the Master.

The Backup routers wait for a period of time called the dead interval for a Hello message from the Master. If a Backup router does not receive a Hello message by the time the dead interval expires, the Backup router assumes that the Master router is dead and negotiates with the other Backup routers to select a new Master router. The Backup router with the highest priority becomes the new Master.

Master and Owner backup routers

If the Owner becomes unavailable, but then comes back online, the Owner again becomes the Master router. The Owner becomes the Master router again because it has the highest priority. The Owner always becomes the Master again when the Owner comes back online.

NOTE

If you configure a track port on the Owner and the track port is down, the Owner priority is changed to the track priority. In this case, the Owner does not have a higher priority than the Backup router that is acting as the Master router and the Owner therefore does not resume its position as the Master router. For more information about track ports, refer to [“Track ports and track priority”](#) on page 1654.

By default, if a Backup is acting as the Master, and the original Master is still unavailable, another Backup can “preempt” the Backup that is acting as the Master. This can occur if the new Backup router has a higher priority than the Backup router that is acting as the Master. You can disable this behavior. When you disable preemption, a Backup router that has a higher priority than the router that is currently acting as the Master does not preempt the new Master by initiating a new Master negotiation. Refer to [“Backup preempt configuration”](#) on page 1678.

NOTE

Regardless of the setting for the preempt parameter, the Owner always becomes the Master again when it comes back online.

Track ports and track priority

The Brocade implementation of VRRP enhances the protocol by giving a VRRP router the capability to monitor the state of the interfaces on the other end of the route path through the router. For example, in [Figure 185](#) on page 1651, interface e1/6 on Switch 1 owns the IP address to which Host1 directs route traffic on its default gateway. The exit path for this traffic is through the Switch 1 e2/4 interface.

Suppose interface e2/4 goes down. Even if interface e1/6 is still up, Host1 is cut off from other networks. In conventional VRRP, Switch 1 would continue to be the Master router despite the unavailability of the exit interface for the path the router is supporting. However, if you configure interface e1/6 to track the state of interface e2/4, if e2/4 goes down, interface e1/6 responds by changing the Switch 1 VRRP priority to the value of the track priority. In the configuration shown in [Figure 185](#) on page 1651, the Switch 1 priority changes from 255 to 20. One of the parameters contained in the Hello messages the Master router sends to its Backup routers is the Master router priority. If the track port feature results in a change in the Master router priority, the Backup routers quickly become aware of the change and initiate a negotiation to become the Master router.

In [Figure 185](#) on page 1651, the track priority results in the Switch 1 VRRP priority becoming lower than the Switch 2 VRRP priority. As a result, when Switch 2 learns that it now has a higher priority than Switch 1, Switch 2 initiates negotiation to become the Master router and becomes the new Master router, thus providing an open path for the Host1 traffic. To take advantage of the track port feature, make sure the track priorities are always lower than the VRRP priorities. The default track priority for the router that owns the VRID IP addresses is 2. The default track priority for Backup routers is 1. If you change the track port priorities, make sure you assign a higher track priority to the Owner of the IP addresses than the track priority you assign on the Backup routers.

Suppression of RIP advertisements for backed-up interfaces

The Brocade implementation also enhances VRRP by allowing you to configure the protocol to suppress RIP advertisements for the backed-up paths from Backup routers. Normally, a VRRP Backup router includes route information for the interface it is backing up in RIP advertisements. As a result, other routers receive multiple paths for the interface and might sometimes unsuccessfully use the path to the Backup router rather than the path to the Master router. If you enable the Brocade implementation of VRRP to suppress the VRRP Backup routers from advertising the backed-up interface in RIP, other routers learn only the path to the Master router for the backed-up interface.

Authentication

The Brocade implementations of VRRP and VRRP-E can use simple passwords to authenticate VRRP and VRRP-E packets. VRRP-E can also use HMAC-MD5-96 to authenticate VRRP-E packets.

VRRP and VRRP-E authentication is configured on the router interfaces. The VRRP authentication configuration of every router interface must match. For example, if you want to use simple passwords to authenticate VRRP traffic within a router, you must configure VRRP simple password authentication with the same password on all of the participating router interfaces.

NOTE

The HMAC-MD5-96 authentication type is supported for VRRP-E, but not supported for VRRP.

NOTE

Authentication is not supported for VRRP v3.

Independent operation of VRRP alongside RIP, OSPF, and BGP4

VRRP operation is independent of RIP, OSPF, and BGP4; therefore, RIP, OSPF, and BGP4 are not affected if VRRP is enabled on one of these interfaces.

Dynamic VRRP configuration

All VRRP global and interface parameters take effect immediately. You do not need to reset the system to place VRRP configuration parameters into effect.

VRRP-E overview

The most important difference between VRRP and VRRP-E is that all VRRP-E routers are Backup routers; there is no Owner router. VRRP-E overcomes the limitations in standard VRRP by removing the Owner.

NOTE

VRRP-E is supported in the edge Layer 3 and full Layer 3 code only. It is not supported in the base Layer 3 code.

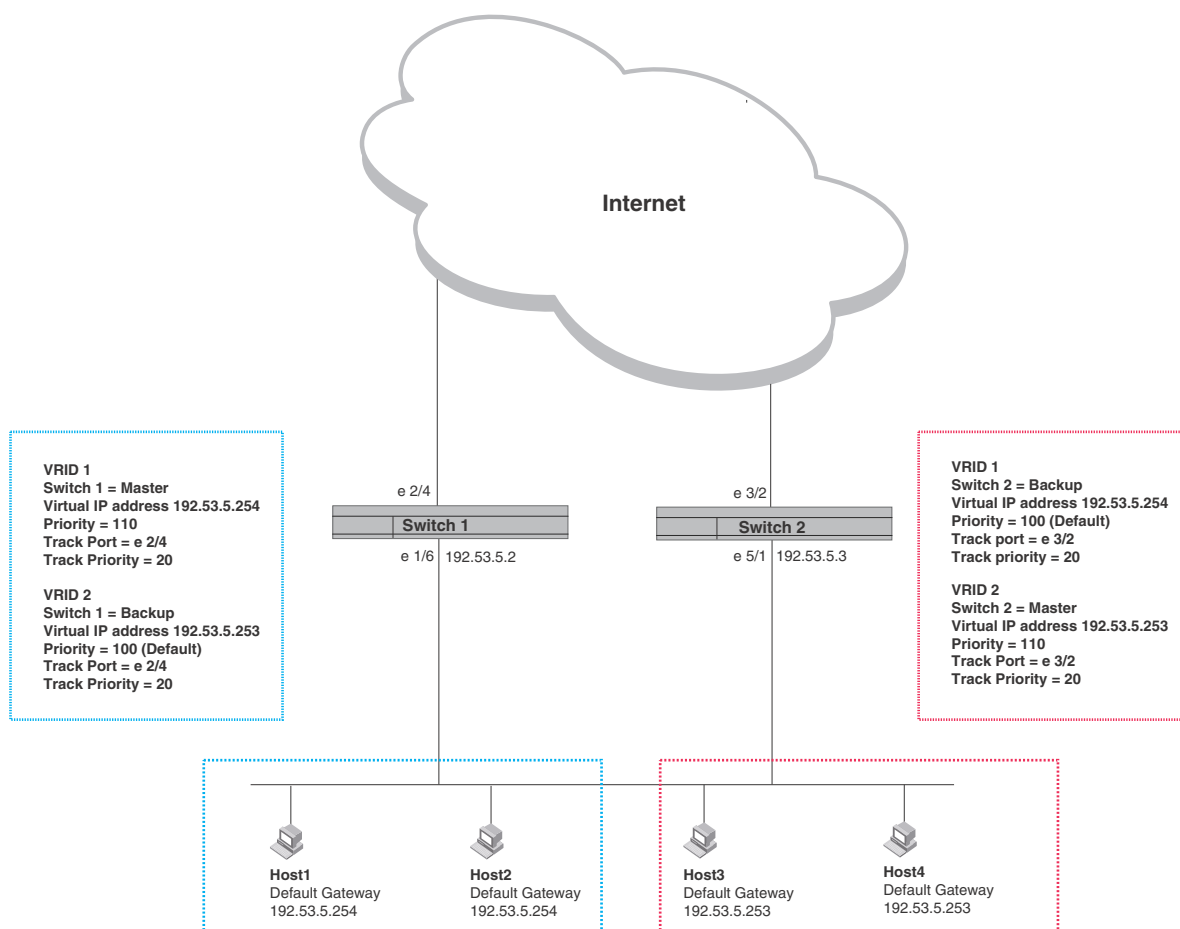

The following points explain how VRRP-E differs from VRRP:

- Owners and Backup routers
 - VRRP has an Owner and one or more Backup routers for each VRID. The Owner is the router on which the VRID's IP address is also configured as a real address. All the other routers supporting the VRID are Backup routers.
 - VRRP-E does not use Owners. All routers are Backup routers for a given VRID. The router with the highest priority becomes the Master. If there is a tie for highest priority, the router with the highest IP address becomes the Master. The elected Master owns the virtual IP address and answers pings and ARP requests.
- VRID's IP address
 - VRRP requires that the VRID's IP address also be a real IP address configured on the VRID's interface on the Owner.
 - VRRP-E requires only that the VRID be in the same subnet as an interface configured on the VRID's interface. VRRP-E does not allow you to specify a real IP address configured on the interface as the VRID IP address.

- VRID's MAC address
 - VRRP uses the source MAC address as a virtual MAC address defined as 00-00-5E-00-01-<vrid>, where <vrid> is the VRID. The Master owns the virtual MAC address.
 - VRRP-E uses the MAC address of the interface as the source MAC address. The MAC address is 02-04-80-<hash-value>-<vrid>, where <hash-value> is a two-octet hashed value for the IP address and <vrid> is the VRID.
- Hello packets
 - VRRP sends Hello messages to IP Multicast address 224.0.0.18.
 - VRRP-E uses UDP to send Hello messages in IP multicast messages. The Hello packets use the MAC address of the interface and the IP address as the source addresses. The destination MAC address is 01-00-5E-00-00-02, and the destination IP address is 224.0.0.2 (the well-known IP multicast address for "all routers"). Both the source and destination UDP port number is 8888. VRRP-E messages are encapsulated in the data portion of the packet.
- Track ports and track priority
 - VRRP changes the priority of the VRID to the track priority, which typically is lower than the VRID priority and lower than the VRID priorities configured on the Backup routers. For example, if the VRRP interface priority is 100 and a tracked interface with track priority 20 goes down, the software changes the VRRP interface priority to 20.
 - VRRP-E reduces the priority of a VRRP-E interface by the amount of a tracked interface priority if the tracked interface link goes down. For example, if the VRRP-E interface priority is 200 and a tracked interface with track priority 20 goes down, the software changes the VRRP-E interface priority to 180. If another tracked interface goes down, the software reduces the VRID priority again, by the amount of the tracked interface track priority.
- VRRP-E can use HMAC-MD5-96 for authenticating VRRP-E packets. VRRP can use only simple passwords.

Figure 186 shows an example of a VRRP-E configuration.

FIGURE 186 Switch 1 and Switch 2 are configured to provide dual redundant network access for the host

In this example, Switch 1 and Switch 2 use VRRP-E to load share as well as provide redundancy to the hosts. The load sharing is accomplished by creating two VRRP-E groups. Each group has its own virtual IP addresses. Half of the clients point to VRID 1's virtual IP address as their default gateway and the other half point to VRID 2's virtual IP address as their default gateway. This organization enables some of the outbound Internet traffic to go through Switch 1 and the rest to go through Switch 2.

Switch 1 is the Master router for VRID 1 (backup priority = 110) and Switch 2 is the Backup router for VRID 1 (backup priority = 100). Switch 1 and Switch 2 both track the uplinks to the Internet. If an uplink failure occurs on Switch 1, its backup priority is decremented by 20 (track priority = 20), so that all traffic destined to the Internet is sent through Switch 2 instead.

Similarly, Switch 2 is the Master router for VRID 2 (backup priority = 110) and Switch 1 is the Backup router for VRID 2 (backup priority = 100). Switch 1 and Switch 2 are both tracking the uplinks to the Internet. If an uplink failure occurs on Switch 2, its backup priority is decremented by 20 (track priority = 20), so that all traffic destined to the Internet is sent through Switch 1 instead.

ARP behavior with VRRP-E

In the VRRP-E implementation, the source MAC address of the gratuitous Address Resolution Protocol (ARP) request sent by the VRRP-E Master router is the VRRP-E virtual MAC address. When the router (either the Master or Backup router) sends an ARP request or reply packet, the sender's MAC address becomes the MAC address of the interface on the router. When an ARP request packet for the virtual router IP address is received by the Backup router, it is forwarded to the Master router to resolve the ARP request. Only the Master router answers the ARP request for the virtual router IP address.

Comparison of VRRP and VRRP-E

This section compares router redundancy protocols.

VRRP

VRRP is a standards-based protocol, described in RFC 2338. The Brocade implementation of VRRP contains the features in RFC 2338. The Brocade implementation also provides the following additional features:

- Track ports – A Brocade feature that enables you to diagnose the health of all the Layer 3 switch ports used by the backed-up VRID, instead of only the port connected to the client subnet. Refer to [“Track ports and track priority”](#) on page 1654.
- Suppression of RIP advertisements on Backup routers for the backed-up interface – You can enable the Layer 3 switches to advertise only the path to the Master router for the backed-up interface. Normally, a VRRP Backup router includes route information for the interface it is backing up in RIP advertisements.

Brocade Layer 3 switches configured for VRRP can interoperate with third-party routers using VRRP.

VRRP-E

VRRP-E is a Brocade protocol that provides the benefits of VRRP without the limitations. VRRP-E is unlike VRRP in the following ways:

- There is no “Owner” router. You do not need to use an IP address configured on one of the Layer 3 switches as the virtual router ID (VRID), which is the address you are backing up for redundancy. The VRID is independent of the IP interfaces configured in the Layer 3 switches. As a result, the protocol does not have an “Owner” as VRRP does.
- There is no restriction on which router can be the default Master router. In VRRP, the “Owner” (the Layer 3 switch on which the IP interface that is used for the VRID is configured) must be the default Master.

Brocade Layer 3 switches configured for VRRP-E can interoperate only with other Brocade Layer 3 switches.

Architectural differences between VRRP and VRRP-E

The protocols have the following architectural differences.

Management protocol

- VRRP – VRRP routers send VRRP Hello and Hello messages to IP Multicast address 224.0.0.18.
- VRRP-E – VRRP-E sends messages to destination MAC address 01-00-5E-00-00-02 and destination IP address 224.0.0.2 (the standard IP multicast address for “all routers”).

Virtual router IP address (the address you are backing up)

- VRRP – The virtual router IP address is the same as an IP address or virtual interface configured on one of the Layer 3 switches, which is the “Owner” and becomes the default Master.
- VRRP-E – The virtual router IP address is the gateway address you want to back up, but does not need to be an IP interface configured on one of the Layer 3 switch ports or a virtual interface.

Master and Backup routers

- VRRP – The “Owner” of the IP address of the VRID is the default Master and has the highest priority (255). The precedence of the Backup routers is determined by their priorities. The default Master is always the Owner of the IP address of the VRID.
- VRRP-E – The Master and Backup routers are selected based on their priority. You can configure any of the Layer 3 switches to be the Master by giving it the highest priority. There is no Owner.

VRRP and VRRP-E parameters

Table 276 lists the VRRP and VRRP-E parameters. Most of the parameters and default values are the same for both protocols. The exceptions are noted in the table.

TABLE 276 VRRP and VRRP-E parameters

Parameter	Description	Default	For more information
Protocol	The Virtual Router Redundancy Protocol (VRRP) based on RFC 2338 or VRRP-Extended, the Brocade-enhanced implementation of VRRP.	Disabled NOTE: Only one of the protocols can be enabled at a time.	page 1664 page 1668
VRRP or VRRP-E router	The Brocade Layer 3 switch active participation as a VRRP or VRRP-E router. Enabling the protocol does not activate the Layer 3 switch for VRRP or VRRP-E. You must activate the switch as a VRRP or VRRP-E router after you configure the VRRP or VRRP-E parameters.	Inactive	page 1664 page 1668
Virtual Router ID (VRID)	The ID of the virtual router you are creating by configuring multiple routers to back up an IP interface. You must configure the same VRID on each router that you want to use to back up the address.	None	page 1652 page 1664 page 1668
Virtual Router IP address	This is the address you are backing up. <ul style="list-style-type: none"> VRRP – The virtual router IP address must be a real IP address configured on the VRID interface on one of the VRRP routers. This router is the IP address Owner and is the default Master. VRRP-E – The virtual router IP address must be in the same subnet as a real IP address configured on the VRRP-E interface, but cannot be the same as a real IP address configured on the interface. 	None	page 1652 page 1664 page 1668
VRID MAC address	The source MAC address in VRRP or VRRP-E packets sent from the VRID interface, and the destination for packets sent to the VRID: <ul style="list-style-type: none"> VRRP – A virtual MAC address defined as 00-00-5E-00-01-<i><vrid></i> for IPv4 VRRP, and 00-00-5E-00-02-<i><vrid></i> for VRRP v3. The Master owns the virtual MAC address. VRRP-E – A virtual MAC address defined as 02-E0-52-<i><hash-value></i>-<i><vrid></i> for IPv4 VRRP-E and IPv6 VRRP-E, where <i><hash-value></i> is a two-octet hashed value for the IP address and <i><vrid></i> is the ID of the virtual router. 	Not configurable	page 1652

TABLE 276 VRRP and VRRP-E parameters (Continued)

Parameter	Description	Default	For more information
Authentication type	<p>The type of authentication the VRRP or VRRP-E interfaces use to validate VRRP or VRRP-E packets.</p> <ul style="list-style-type: none"> No authentication – The interfaces do not use authentication. This is the VRRP default. Simple – The interface uses a simple text-string as a password in packets sent on the interface. If the interface uses simple password authentication, the VRID configured on the interface must use the same authentication type and the same password. HMAC-MD5-96 (VRRP-E only) – The interface uses HMAC-MD5-96 authentication for VRRP-E packets. <p>NOTE: HMAC-MD5-96 authentication is only supported for IPv4 or IPv6 VRRP-E. HMAC-MD5-96 is not supported by VRRP. Authentication is not supported for VRRP v3.</p>	No authentication	page 1654 page 1671
Router type	<p>Whether the router is an Owner or a Backup.</p> <ul style="list-style-type: none"> Owner (VRRP only) – The router on which the real IP address used by the VRID is configured. Backup – Routers that can provide routing services for the VRID but do not have a real IP address matching the VRID. 	<p>VRRP – The Owner is always the router that has the real IP address used by the VRID. All other routers for the VRID are Backups.</p> <p>VRRP-E – All routers for the VRID are Backups.</p>	page 1673
Backup priority	<p>A numeric value that determines a Backup router's preferability for becoming the Master for the VRID. During negotiation, the router with the highest priority becomes the Master.</p> <ul style="list-style-type: none"> VRRP – The Owner has the highest priority (255); other routers (backups) can have a priority from 3 through 254. VRRP-E – All routers are Backups and have the same priority by default. <p>If two or more Backups are tied with the highest priority, the Backup interface with the highest IP address becomes the Master for the VRID.</p>	<p>VRRP v2 and IPv6 VRRP v3 - The value is 255 for the Owner and 100 for the Backups.</p> <p>VRRP-E v2 and IPv6 VRRP-E v3 - The value is 100 for all Backups.</p>	page 1673
Suppression of RIP advertisements	<p>A router that is running RIP normally advertises routes to a backed-up VRID even when the router is not currently the active router for the VRID. Suppression of these advertisements helps ensure that other routers do not receive invalid route paths for the VRID.</p> <p>NOTE: Suppression of RIP advertisements is not supported for VRRP v3 and VRRP-E v3.</p>	Disabled	page 1674
Hello interval	<p>The number of seconds or milliseconds between Hello messages from the Master to the Backups for a given VRID. The interval can be from 1 through 84 seconds for VRRP v2, VRRP-E v2, and IPv6 VRRP-E. The interval for VRRP v3 can be from 100 through 8400 milliseconds.</p>	<p>One second (VRRP v2 and VRRP-E v2, and IPv6 VRRP-E) 1000 milliseconds (VRRP v3).</p>	page 1653 page 1675

TABLE 276 VRRP and VRRP-E parameters (Continued)

Parameter	Description	Default	For more information
Dead interval	<p>The number of seconds or milliseconds a Backup waits for a Hello message from the Master for the VRID before determining that the Master is no longer active.</p> <p>If the Master does not send a Hello message before the dead interval expires, the Backups negotiate (compare priorities) to select a new Master for the VRID.</p>	<p>The dead interval calculation for VRRP v6 or VRRP-E v6 is:</p> <p>Dead Interval: (3 X Hello Interval) + Skew Time</p> <p>Skew Time is 256 - Priority X Hello Interval / 256.</p> <p>For VRRP v3, the default is 3600 milliseconds. The configurable range is from 100 through 8400 milliseconds.</p> <p>For VRRP-E v3, the default is 3600 milliseconds. The configurable range is from 1 through 84 seconds.</p>	page 1653 page 1676
Backup Hello interval	<p>The number of seconds between Hello messages from a Backup to the Master.</p> <p>The message interval can be from 60 through 3600 seconds.</p> <p>You must enable the Backup to send the messages. The messages are disabled by default on Backups. The current Master (whether the VRRP Owner or a Backup) sends Hello messages by default.</p>	<p>Disabled</p> <p>60 seconds when enabled</p>	page 1653 page 1676
Track port	<p>Another Layer 3 switch port or virtual interface whose link status is tracked by the VRID interface.</p> <p>If the link for a tracked interface goes down, the VRRP or VRRP-E priority of the VRID interface is changed, causing the devices to renegotiate for the Master.</p> <p>NOTE: Track port is not supported by VRRP v3.</p>	None	page 1654 page 1677
Track priority	<p>A VRRP or VRRP-E priority value assigned to the tracked ports. If a tracked port link goes down, the VRID port VRRP or VRRP-E priority changes:</p> <ul style="list-style-type: none"> • VRRP – The priority changes to the value of the tracked port priority. • VRRP-E – The VRID port priority is reduced by the amount of the tracked port priority. <p>NOTE: Track priority is not supported by VRRP v3.</p>	<p>VRRP – 2</p> <p>VRRP-E – 5</p>	page 1654 page 1677
Backup preempt mode	Prevents a Backup with a higher VRRP priority from taking control of the VRID from another Backup that has a lower priority but has already assumed control of the VRID.	Enabled	page 1678
Timer scale	<p>Adjusts the timers for the Hello interval, Dead interval, Backup Hello interval, and Hold-down interval.</p> <p>NOTE: The timer scale is not supported for IPv6 VRRP v3.</p>	1	page 1678

TABLE 276 VRRP and VRRP-E parameters (Continued)

Parameter	Description	Default	For more information
VRRP-E slow start timer	Causes a specified amount of time to elapse between the time the original Master is restored and when it takes over from the Backup. This interval allows time for OSPF convergence when the Master is restored. For VRRP-E only.	Disabled	page 1679
Short-path forwarding	Enables VRRP-E extension for server virtualization. If enabled, the traffic that is destined to the clients travels through the short-path forwarding path to reach the client (as shown in Figure 187 on page 1681). Any packets coming from the local subnet of the virtual IP address are routed to the VRRP-E Master router. For example, with VRRP-E extension for server virtualization enabled, the traceroute output shows one extra hop that displays the Backup router's interface IP address.	Disabled	page 1674

Note regarding disabling VRRP or VRRP-E

NOTE

Disabling VRRP or VRRP-E is supported by IPv4 VRRP v2, and IPv6 VRRP and IPv6 VRRP-E v3.

If you disable VRRP or VRRP-E, the Layer 3 switch removes all the configuration information for the disabled protocol from the running-config file. Moreover, when you save the configuration to the startup-config file after disabling one of these protocols, all the configuration information for the disabled protocol is removed from the startup-config file.

The CLI displays a warning message such as the following.

```
Brocade Router1(config-vrrp-router)#no router vrrp
router vrrp mode now disabled. All vrrp config data will be lost when writing to
flash!
```

If you have disabled the protocol but have not yet saved the configuration to the startup-config file and reloaded the software, you can restore the configuration information by re-entering the command to enable the protocol (for example, **router vrrp**). If you have already saved the configuration to the startup-config file and reloaded the software, the information is gone.

If you are testing a VRRP or VRRP-E configuration and are likely to disable and re-enable the protocol, you may want to make a backup copy of the startup-config file containing the protocol configuration information. This way, if you remove the configuration information by saving the configuration after disabling the protocol, you can restore the configuration by copying the backup copy of the startup-config file onto the flash memory.

Basic VRRP parameter configuration

To implement a simple VRRP configuration using all the default values, enter the commands shown in the following sections.

Configuration rules for VRRP

- The interfaces of all routers in a VRID must be in the same IP subnet.
- The IP addresses associated with the VRID must already be configured on the router that will be the Owner.
- An IP address associated with the VRID must be on only one router.
- The Hello interval must be set to the same value on the Owner and Backup routers for the VRID.
- The dead interval must be set to the same value on the Owner and Backup routers for the VRID.
- The track priority on a router must be lower than the router VRRP priority. Also, the track priority on the Owner must be higher than the track priority on the Backup routers.

NOTE

IPv6 VRRP and IPv6 VRRP-E v3 are supported on Brocade FESX, FSX 800, FSX 1600, and FCX IPv6 modules. IPv4 VRRP v3 is not supported on FCX devices.

NOTE

When you use the **router vrrp** command or the **ipv6 router vrrp** command to enter the VRRP configuration mode, the command prompt does not change and results in the following general configuration command prompt: `Brocade(config)#`. This differs from entering the VRRP extended mode, where entering the **router vrrp-extended** command results in a command prompt such as the following: `(config-VRRP-E-router)#`. For IPv6 VRRP extended mode, when entering the **ipv6 router vrrp-extended** command, this results in a command prompt such as the following: `(config-ipv6-VRRP-E-router)#`.

Configuring the Owner for IPv4 VRRP

To configure the VRRP Owner router for IPv4, enter the following commands on the router.

```
Brocade Router1(config)#router vrrp
Brocade Router1(config)#interface ethernet 1/6
Brocade Router1(config-if-1/6)#ip-address 192.53.5.1
Brocade Router1(config-if-1/6)#ip vrrp vrid 1
Brocade Router1(config-if-1/6-vrid-1)#owner
Brocade Router1(config-if-1/6-vrid-1)#ip-address 192.53.5.1
Brocade Router1(config-if-1/6-vrid-1)#activate
```

Syntax: [no] router vrrp

Syntax: [no] ip-address <ip-addr>

Syntax: [no] ip vrrp vrid <num>

Syntax: [no] owner [track-priority <value>]

Syntax: [no] activate

The `<ip-addr>` variable specifies the IPv4 address of the Owner router.

The IP address you assign to the Owner must be an IP address configured on an interface that belongs to the virtual router.

The `<num>` variable specifies the virtual router ID.

The **track-priority** `<value>` option changes the track-port priority for this interface and the VRID from the default (2) to a value from 1 through the maximum VRID supported by the device.

Configuring the Owner for IPv6 VRRP

To configure the VRRP Owner router for IPv6, enter the following commands on the router.

NOTE

You must first configure the **ipv6 unicast-routing** command at the global configuration level to enable IPv6 VRRP on the router.

```
Brocade Router1(config)# ipv6 unicast-routing
Brocade Router1(config)# ipv6 router vrrp
Brocade Router1(config)# interface ethernet 1/6
Brocade Router1(config-if-e10000-1/6)# ipv6-address 3013::1/64
Brocade Router1(config-if-e10000-1/6)# ipv6 vrrp vrid 1
Brocade Router1(config-if-e10000-1/6-vrid-1)# owner
Brocade Router1(config-if-e10000-1/6-vrid-1)# ipv6-address 3013::1
Brocade Router1(config-if-e10000-1/6-vrid-1)# activate
VRRP router 1 for this interface is activating
```

Syntax: `[no] ipv6 unicast-routing`

Syntax: `[no] ipv6 router vrrp`

Syntax: `[no] ipv6-address <ipv6-address>`

Syntax: `[no] ipv6 vrrp vrid <num>`

Syntax: `[no] owner`

Syntax: `[no] activate`

The `<num>` variable specifies the virtual router ID.

The `<ipv6-addr>` variable specifies the IPv6 address of the Owner router.

The IP address you assign to the Owner must be an IP address configured on an interface that belongs to the virtual router.

The **ipv6 router vrrp** command enables IPv6 VRRP v3 routing on the interface. All IPv6 VRRP router instances for a VRID are also enabled on the interface.

When the **no ipv6 router vrrp** command is enabled, all IPv6 VRRP router instances for a specific VRID are deleted from the interface, and the running configuration is lost when writing to flash. You must enable the **write memory** command to save your configuration. The following message is displayed when the **no ipv6 router vrrp** command is enabled.

```
Router1(config)#no ipv6 router vrrp
ipv6 router vrrp is disabled. All vrrp (ipv6) config data will be lost when
writing to flash!!
```

Configuring a Backup for IPv4 VRRP

To configure the VRRP Backup router for IPv4, enter the following commands.

```
Brocade Router2(config)#router vrrp
Brocade Router2(config)#interface ethernet 1/5
Brocade Router2(config-if-1/5)#ip-address 192.53.5.3
Brocade Router2(config-if-1/5)#ip vrrp vrid 1
Brocade Router2(config-if-1/5-vrid-1)#backup
Brocade Router2(config-if-1/5-vrid-1)#advertise backup
Brocade Router2(config-if-1/5-vrid-1)#ip-address 192.53.5.1
Brocade Router2(config-if-1/5-vrid-1)#activate
VRRP router 2 for interface is activating
```

Syntax: [no] router vrrp

Syntax: [no] ip-address <ip-addr>

Syntax: [no] ip vrrp vrid <num>

Syntax: [no] backup [priority <value>] [track-priority <value>]

Syntax: [no] advertise backup

Syntax: [no] activate

When you configure a Backup router, the router interface on which you are configuring the VRID must have a real IP address that is in the same subnet as the address associated with the VRID by the Owner. However, the address cannot be the same.

The <num> variable specifies the virtual router ID.

The **priority** <value> option specifies the VRRP priority for this virtual router. You can specify a value from 3 through 254. The default is 100.

The **track-priority** <value> option specifies that VRRP monitors the state of the interface. You can specify a value from 3 through 254. The default is 100.

By default, Backup routers do not send Hello messages to advertise themselves to the Master. The **advertise backup** command is used to enable a Backup router to send Hello messages to the Master.

Configuring a Backup for IPv6 VRRP

To configure the VRRP Backup router for IPv6, enter the following commands.

```
Brocade Router2(config)# ipv6 router vrrp
Brocade Router2(config)# interface ethernet 1/5
Brocade Router2(config-if-e10000-1/5)# ipv6-address 3013::3/64
Brocade Router2(config-if-e10000-1/5)# ipv6 vrrp vrid 1
Brocade Router2(config-if-e10000-1/5-vrid-1)# backup
Brocade Router2(config-if-e10000-1/5-vrid-1)# advertise backup
Brocade Router2(config-if-e10000-1/5-vrid-1)# ipv6-address 3013::1
Brocade Router2(config-if-e10000-1/5-vrid-1)# activate
```

When you configure a Backup router, the router interface on which you are configuring the VRID must have a real IP address that is in the same subnet as the address associated with the VRID by the Owner. However, the address cannot be the same.

Syntax: [no] ipv6 router vrrp

Syntax: [no] ipv6-address <ipv6-addr>

Syntax: [no] ipv6 vrrp vrid <num>

Syntax: [no] backup [priority <value>]

Syntax: [no] advertise backup

Syntax: [no] activate

The <ipv6-addr> variable specifies the IPv6 address of the Backup router.

The <num> variable specifies the virtual router ID.

The **priority** <value> option specifies the IPv6 VRRP priority for this virtual Backup router. You can specify a value from 3 through 254. The default is 100.

By default, Backup routers do not send Hello messages to advertise themselves to the Master. The **advertise backup** command is used to enable a Backup router to send Hello messages to the Master.

Configuration considerations for IPv6 VRRP v3 and IPv6 VRRP-E v3 support on Brocade devices

Consider the following when enabling IPv6 VRRP v3 mode and IPv6 VRRP-E v3 mode on FCX devices:

- You can configure only one protocol (Layer 3 VSRP, VRRP, or VRRP-E) on a router at a single time. However, VRRP or VRRP-E can be configured with IPv4 and IPv6 concurrently on a router.
- Scale timer configuration does not affect timer values, nor does it scale timer values for virtual routers configured with sub-second time values for IPv6 VRRP and IPv4 VRRP v3 modes.
- Abdication of a VRRP Owner router in an IPv6 environment is not supported. Abdication of an Owner router is a Brocade-specific enhancement to VRRP. Abdication of an Owner router is possible by changing the Owner's priority, or by configuring track ports for an Owner router.
 - For IPv6 VRRP v3 only, the tracking port configuration is not allowed if the router is configured as the VRRP Owner. This conforms to RFC 5798.
 - For the IPv6 VRRP v3 Owner router only, the priority configuration is not allowed. The Owner router priority is always 255. This conforms to RFC 5798.
- Hitless switchover is not supported for IPv6 VRRP and IPv6 VRRP-E environments.
- Interoperability is not supported for a VRID when VRRP routers are configured as VRRP v2 or v3.
- Brocade does not recommend that you re-use the same VRID across IPv6 VRRP-E and IPv4 VRRP-E if they are in the same broadcast domain.
- There is no specified restriction for configuring VRRP or VRRP-E instances if they are within the maximum VRID range. The maximum number of supported VRRP or VRRP-E router instances is 254 for IPv4 environments. The maximum number of supported VRRP or VRRP-E router instances is 128 for IPv6 environments.

Basic VRRP-E parameter configuration

The following sections describe the configuration of the parameters specific to IPv4 and IPv6 VRRP-E.

Configuration rules for VRRP-E

Consider the following rules when configuring VRRP-E:

- The interfaces of all routers in a VRID must be in the same IP subnet.
- The IP address associated with the VRID cannot be configured on any of the Layer 3 switches.
- The Hello interval must be set to the same value on all the Layer 3 switches.
- The dead interval must be set to the same value on all the Layer 3 switches.
- The track priority for a VRID must be lower than the VRRP-E priority.

Configuring IPv4 VRRP-E

VRRP-E is configured at the interface level. To implement a simple IPv4 VRRP-E configuration using all the default values, enter commands such as the following on each Layer 3 switch.

```
Brocade Router2(config)#router vrrp-extended
Brocade Router2(config)#interface ethernet 1/5
Brocade Router2(config-if-1/5)#ip-address 192.53.5.3
Brocade Router2(config-if-1/5)#ip vrrp-extended vrid 1
Brocade Router2(config-if-1/5-vrid-1)#backup
Brocade Router2(config-if-1/5-vrid-1)#advertise backup
Brocade Router2(config-if-1/5-vrid-1)#ip-address 192.53.5.254
Brocade Router2(config-if-1/5-vrid-1)#activate
```

Syntax: [no] router vrrp-extended

Syntax: [no] ip-address <ip-address>

Syntax: [no] ip vrrp-extended vrid <vrid>

Syntax: [no] backup [priority <value>] [track-priority <value>]

Syntax: [no] advertise backup

Syntax: [no] activate

The <vrid> variable specifies the virtual router ID.

The <ip-addr> variable specifies the IPv4 address of the router.

You must identify a VRRP-E router as a Backup before you can activate the virtual router on a Brocade device. However, after you configure the virtual router, you can use the **backup** command to change its priority or track priority.

The **priority** <value> option specifies the IPv4 VRRP-E priority for this virtual Backup router. You can specify a value from 3 through 254. The default is 100.

The **track-priority** <value> option changes the track port priority of a Backup router. You can specify a value from 1 through 254. The default is 2.

NOTE

You also can use the **enable** command to activate the configuration. This command does the same thing as the **activate** command.

Configuring IPv6 VRRP-E

To implement an IPv6 VRRP-E configuration using all the default values, enter the following commands.

NOTE

You must first configure the **ipv6 unicast-routing** command at the global configuration level to enable IPv6 VRRP-E on the router.

```
Brocade Router2(config)# ipv6 unicast-routing
Brocade Router2(config)# ipv6 router vrrp-extended
Brocade Router2(config-ipv6-VRRP-E-router)# interface ethernet 1/5
Brocade Router2(config-if-e10000-1/5)# ipv6-address 3013::2/64
Brocade Router2(config-if-e10000-1/5)# ipv6 vrrp-extended vrid 1
Brocade Router2(config-if-e10000-1/5-vrid-1)# backup priority 50 track-priority
10
Brocade Router2(config-if-e10000-1/5-vrid-1)# ipv6-address 3013::99
Brocade Router2(config-if-e10000-1/5-vrid-1)# activate
```

Syntax: [no] **ipv6 unicast-routing**

Syntax: **ipv6 router vrrp-extended**

Syntax: [no] **ipv6-address** <ipv6-addr>

Syntax: **ipv6 vrrp-extended vrid** <vrid>

Syntax: [no] **backup** [priority <value>] [track-priority <value>]

Syntax: [no] **activate**

The <vrid> variable specifies the virtual router ID.

The <ipv6-addr> variable specifies the IPv6 address of the router.

You must identify a VRRP-E router as a Backup before you can activate the virtual router on a Brocade device. However, after you configure the virtual router, you can use the **backup** command to change its priority or track priority.

The **priority** <value> option specifies the IPv6 VRRP-E priority for this virtual Backup router. You can specify a value from 3 through 254. The default is 100.

The **track-priority** <value> option changes the track port priority of a Backup router. You can specify a value from 1 through 254. The default is 2.

NOTE

You also can use the **enable** command to activate the configuration. This command does the same thing as the **activate** command.

When the **no ipv6 router vrrp-extended** command is enabled, all IPv6 VRRP-E instances for a specific VRID are deleted from the interface, and the running configuration is lost when writing to flash. You must enable the **write memory** command to save your configuration. The following message is displayed when the **no ipv6 router vrrp-extended** command is enabled.

```
Brocade Router2(config)#no ipv6 router vrrp-extended
ipv6 router VRRP-E is disabled. All VRRP-E (ipv6) config data will be lost when
writing to flash!!
```

Additional VRRP and VRRP-E parameter configuration

You can modify the following VRRP and VRRP-E parameters on an individual VRID basis. These parameters apply to both protocols:

- Authentication type (if the interfaces on which you configure the VRID use authentication)
- Router type (Owner or Backup)

NOTE

For VRRP, change the router type only if you have moved the real IP address from one router to another or you accidentally configured the IP address Owner as a Backup.

For VRRP-E, the router type is always Backup. You cannot change the type to Owner.

- Suppression of RIP advertisements on Backup routes for the backed-up interface
- Hello interval
- Dead interval
- Backup Hello messages and message timer (Backup advertisement)
- Track port
- Track priority
- Backup preempt mode
- Timer scale
- VRRP-E slow start timer
- VRRP-E extension for server virtualization (short-path forwarding)

Refer to [“VRRP and VRRP-E parameters”](#) on page 1660 for a summary of the parameters and their defaults.

VRRP and VRRP-E authentication types

This section describes VRRP and VRRP-E authentication parameters.

Configuring authentication type

The Brocade implementation of VRRP and VRRP-E supports the following authentication types for authenticating VRRP and VRRP-E traffic:

- No authentication – The interfaces do not use authentication. This is the default for VRRP and VRRP-E.
- Simple – The interfaces use a simple text-string as a password in packets sent on the interface. If the interfaces use simple password authentication, the VRID configured on the interfaces must use the same authentication type and the same password.

VRRP-E also supports the following authentication type:

- HMAC-MD5-96 – The interfaces use HMAC-MD5-96 authentication for VRRP-E packets.

NOTE

HMAC-MD5-96 authentication is not supported for VRRP.

To configure the VRID interface on Switch 1 for simple password authentication using the password “ourpword”, enter the following commands.

Configuring Switch 1

```
Brocade Switch1(config)#inter e 1/6
Brocade Switch1(config-if-1/6)#ip vrrp auth-type simple-text-auth ourpword
```

VRRP syntax

Syntax: `auth-type no-auth | simple-text-auth <auth-data>`

The **auth-type no-auth** option indicates that the VRID and the interface it is configured on do not use authentication.

The **simple-text-auth <auth-data>** option indicates that the VRID and the interface it is configured on use a simple text password for authentication. The `<auth-data>` variable is the password. If you use this variable, make sure all interfaces on all the routers supporting this VRID are configured for simple password authentication and use the same password.

NOTE

For VRRP v3, authentication is deprecated by RFC 5768.

VRRP-E syntax

For IPv4 VRRP-E:

Syntax: `ip vrrp-extended auth-type no-auth | simple-text-auth <auth-data> | md5-auth [0 | 1] <key>`

For IPv6 VRRP-E:

Syntax: `ipv6 vrrp-extended auth-type no-auth | simple-text-auth <auth-data> | md5-auth [0 | 1] <key>`

The values for the **no-auth** and **simple-text-auth** <auth-data> options are the same as for VRRP.

The **md5-auth** option configures the interface to use HMAC-MD5-96 for VRRP-E authentication.

The <key> variable is the MD5 encryption key, which can be up to 64 characters long. The optional [0 | 1] parameter configures whether the MD5 password is encrypted, as follows:

- If you do not enter this parameter and enter the key as clear text, the key appears encrypted in the device configuration and command outputs.
- If you enter **0** and enter the key as clear text, the key appears as clear text in the device configuration and command outputs.
- If you enter **1** and enter the key in encrypted format, the key appears in encrypted format in the device configuration and command outputs.

Syslog messages for VRRP-E HMAC-MD5-96 authentication

If an interface is configured with HMAC-MD5-96 authentication, all VRRP-E packets received on this interface are authenticated with the HMAC-MD5-96 algorithm using the shared secret key configured on the interface.

If a packet is received that fails this HMAC-MD5-96 authentication check, the packet gets dropped. Additionally, if syslog is enabled, a syslog message is generated to notify the administrator about an authentication failure. The message includes the VRID received in the packet's VRRP message and the interface on which the packet was received. These syslog messages will be rate limited to 20 log messages within a span of 5 minutes, starting from the first packet received that fails the HMAC-MD5-96 authentication check.

VRRP router type

A VRRP interface is either an Owner or a Backup router for a given VRID. By default, the Owner becomes the Master. A Backup router becomes the Master only if the Master becomes unavailable.

A VRRP-E interface is always a Backup router for its VRID. The Backup router with the highest VRRP priority becomes the Master.

This section describes how to specify the interface type, how to change the type for VRRP, and how to set or change the interface VRRP or VRRP-E priority and track priority for the VRID.

NOTE

You can force a VRRP Master router to abdicate (give away control) of the VRID to a Backup router by temporarily changing the Master VRRP priority to a value less than the Backup. Refer to [“Forcing a Master router to abdicate to a Backup router”](#) on page 1683.

NOTE

The Owner type is not applicable to VRRP-E.

NOTE

The IP addresses you associate with the Owner must be real IP addresses on the interface on which you configure the VRID.

When you configure a Backup router, the router interface on which you are configuring the VRID must have a real IP address that is in the same subnet as the address associated with the VRID by the Owner. However, the address cannot be the same.

Configuring Router 1 as VRRP VRID Owner

To configure Router1 as a VRRP VRID Owner, enter the following commands.

```
Brocade Router1(config)#interface ethernet 1/6
Brocade Router1(config-if-1/6)#ip vrrp vrid 1
Brocade Router1(config-if-1/6-vrid-1)#owner
```

Configuring Router 2 as VRRP Backup

To configure Router2 as a VRRP Backup for the same VRID, and set its VRRP priority, enter the following commands.

```
Brocade Router2(config)#interface ethernet 1/5
Brocade Router2(config-if-1/5)#ip vrrp vrid 1
Brocade Router2(config-if-1/5-vrid-1)#backup priority 120
Brocade Router2(config-if-1/5-vrid-1)#advertise backup
```

Configuring an IPv6 VRRP v3 interface as a Backup for a VRID

To configure an IPv6 VRRP v3 interface as a Backup for a VRID, and set its VRRP priority and track priority, enter commands such as the following.

```
Brocade Router2(config)# interface ethernet 1/5
Brocade Router2(config-if-e10000-1/1)# ipv6 vrrp vrid 1
Brocade Router2(config-if-e10000-1/1-vrid-1)# backup priority 50 track-priority 10
Brocade Router2(config-if-1/1-vrid-1)#advertise backup
```

Configuring an IPv6 VRRP-E v3 interface as a Backup for a VRID

To configure an IPv6 VRRP-E v3 interface as a Backup for a VRID, and set its VRRP-E priority and track priority, enter commands such as the following.

```
Brocade Router2(config)#interface ethernet 1/1
Brocade Router2(config-if-1/1)#ipv6 vrrp-extended vrid 1
Brocade Router2(config-if-1/1-vrid-1)#backup priority 50 track-priority 10
Brocade Router2(config-if-1/1-vrid-1)#advertise backup
```

VRRP v2 and IPv6 VRRP v3 syntax

Syntax: **owner** [**track-priority** <value>]

The **track-priority** <value> option changes the track port priority for this interface and VRID from the default (2) to a value from 1 through 254.

Syntax: **backup** [**priority** <value>] [**track-priority** <value>]

The **priority** <value> option specifies the VRRP priority for this interface and VRID. You can specify a value from 3 through 254. The default is 100.

The **track-priority** <value> option is the same as with the **owner** [**track-priority** <value>] command.

VRRP-E v2 and IPv6 VRRP-E v3 syntax

Syntax: **backup** [**priority** <value>] [**track-priority** <value>]

The software requires you to identify a VRRP-E interface as a Backup for its VRID before you can activate the interface for the VRID. However, after you configure the VRID, you can use this command to change its priority or track priority. The option values are the same as for VRRP.

Suppression of RIP advertisements

NOTE

Suppression of RIPng advertisements on Backup routers for the backup interface is not supported by IPv6 VRRP v3 and IPv6 VRRP-E v3.

Normally, a VRRP or VRRP-E Backup includes route information for the virtual IP address (the backed-up interface) in RIP advertisements. As a result, other routers receive multiple paths for the backed-up interface and might sometimes unsuccessfully use the path to the Backup router rather than the path to the Master.

You can prevent the Backup routers from advertising route information for the backed-up interface by enabling suppression of the advertisements.

Suppressing RIP advertisements for the backed-up interface in Router 2

To suppress RIP advertisements for the backed-up interface in Router 2, enter the following commands.

```
Brocade Router2(config)#router rip
Brocade Router2(config-rip-router)#use-vrrp-path
```

Syntax: `use-vrrp-path`

The syntax is the same for VRRP and VRRP-E.

Hello interval configuration

The Master periodically sends Hello messages to the Backup routers. The Backup routers use the Hello messages as verification that the Master is still online. If the Backup routers stop receiving the Hello messages for the period of time specified by the dead interval, the Backup routers determine that the Master router is dead. At this point, the Backup router with the highest priority becomes the new Master router.

NOTE

The default dead interval is three times the Hello interval plus the Skew time. Generally, if you change the Hello interval, you also should change the dead interval on the Backup routers.

To change the Hello interval on the Master to 10 seconds, enter the following commands.

```
Brocade Router1(config)#interface ethernet 1/6
Brocade Router1(config-if-1/6)#ip vrrp vrid 1
Brocade Router1(config-if-1/6-vrid-1)#hello-interval 10
```

Syntax: `[no] hello-interval <seconds>`

The `<seconds>` variable specifies the Hello interval value from 1 through 84 seconds for VRRP v2, VRRP-E v2, and IPv6 VRRP-E. The default is 1 second.

To change the Hello interval on the Master to 200 milliseconds for IPv6 VRRP v3, enter the following commands.

```
Brocade Router1(config)# interface ethernet 1/6
Brocade Router1(config-if-1/6)# ipv6 vrrp vrid 1
Brocade Router1(config-if-1/6-vrid-1)# hello-interval 200
```

Syntax: `[no] hello-interval <milliseconds>`

The `<milliseconds>` variable can be from 100 through 8400 milliseconds. The default is 1000 milliseconds.

Dead interval configuration

The dead interval is the number of seconds a Backup router waits for a Hello message from the Master before determining that the Master is dead. When Backup routers determine that the Master is dead, the Backup with the highest priority becomes the new Master.

If the value for the dead interval is not configured, then the current dead interval is equal to three times the Hello interval plus the Skew time (where Skew time is equal to $(256 - \text{priority})$ divided by 256).

To change the dead interval on a Backup to 30 seconds, enter the following commands.

```
Brocade Router2(config)#interface ethernet 1/5
Brocade Router2(config-if-e1000-1/5)#ip vrrp vrid 1
Brocade Router2(config-if-e1000-1/5-vrid-1)#dead-interval 30
```

Syntax: `dead-interval <value>`

The `<value>` variable is from 1 through 84 seconds for VRRP v2 and VRRP-E v2. For other versions, the `<value>` variable is from 100 through 8400 milliseconds. The default is 3600 milliseconds.

NOTE

If the `dead-interval` command is not configured on a VRRP v3 interface, then a zero value is displayed in the output of the `show ipv6 VRRP-Extended` command.

Backup Hello message state and interval

NOTE

The `advertise backup` command is supported by IPv4 VRRP v2, and IPv6 VRRP v3 and IPv6 VRRP-E v3.

By default, Backup routers do not send Hello messages to advertise themselves to the Master. You can enable these messages if desired and also change the message interval.

To enable a Backup router to send Hello messages to the Master, enter the following commands.

```
Brocade(config)#router vrrp
Brocade(config)#interface ethernet 1/6
Brocade(config-if-1/6)#ip vrrp vrid 1
Brocade(config-if-1/6-vrid-1)#advertise backup
```

Syntax: `[no] advertise backup`

When you enable a Backup to send Hello messages, the Backup sends a Hello message to the Master every 60 seconds by default. You can change the interval to be up to 3600 seconds. To change the Hello message interval, enter the following commands.

```
Brocade(config)#router vrrp
Brocade(config)#interface ethernet 1/6
Brocade(config-if-1/6)#ip vrrp vrid 1
Brocade(config-if-1/6-vrid-1)#backup-hello-interval 180
```

Syntax: `[no] backup-hello-interval <num>`

The `<num>` variable specifies the message interval and can be from 60 through 3600 seconds. The default is 60 seconds.

The syntax is the same for VRRP v2 and IPv6 VRRP v3, and VRRP-E v2 and IPv6 VRRP-E v3.

Track port configuration

NOTE

Track port is not supported by VRRP v3.

You can configure the VRID on one interface to track the link state of another interface on the Layer 3 switch. This capability is quite useful for tracking the state of the exit interface for the path for which the VRID is providing redundancy. Refer to [“Track ports and track priority”](#) on page 1654.

To configure interface 1/6 on Router 1 to track interface 2/4, enter the following commands.

```
Brocade Router1(config)#interface ethernet 1/6
Brocade Router1(config-if-1/6)#ip vrrp vrid 1
Brocade Router1(config-if-1/6-vrid-1)#track-port ethernet 2/4
```

Syntax: **track-port ethernet** [<slotnum>/<portnum> | **ve** <num>]

The syntax is the same for VRRP and VRRP-E.

Track priority configuration

NOTE

Track priority is not supported by IPv6 VRRP v3.

When you configure a VRID to track the link state of other interfaces, and one of the tracked interfaces goes down, the software changes the VRRP or VRRP-E priority of the VRID interface:

- For VRRP, the software changes the priority of the VRID to the track priority, which typically is lower than the VRID priority and lower than the VRID priorities configured on the Backups. For example, if the VRRP interface priority is 100 and a tracked interface with track priority 60 goes down, the software changes the VRRP interface priority to 60.
- For VRRP-E, the software reduces the VRID priority by the amount of the priority of the tracked interface that went down. For example, if the VRRP-E interface priority is 100 and a tracked interface with track priority 60 goes down, the software changes the VRRP-E interface priority to 40. If another tracked interface goes down, the software reduces the VRID priority again, by the amount of the tracked interface track priority.

The default track priority for an Owner for VRRP v2, IPv6 VRRP v3, and VRRP-E v2 and IPv6 VRRP-E v3 is 2. The default track priority for Backup routers is 1.

You enter the track priority as a value with the **owner** or **backup** command. Refer to [“Track port configuration”](#) on page 1677.

Syntax: **owner** [track-priority <value>]

Syntax: **backup** [priority <value>] [track-priority <value>]

The syntax is the same for VRRP and VRRP-E.

Backup preempt configuration

By default, a Backup that has a higher priority than another Backup that has become the Master can preempt the Master, and take over the role of Master. If you want to prevent this behavior, disable preemption.

Preemption applies only to Backups and takes effect only when the Master has failed and a Backup has assumed ownership of the VRID. The feature prevents a Backup with a higher priority from taking over as Master from another Backup that has a lower priority but has already become the Master of the VRID.

Preemption is especially useful for preventing flapping in situations where there are multiple Backups and a Backup with a lower priority than another Backup has assumed ownership, because the Backup with the higher priority was unavailable when ownership changed.

If you enable the non-preempt mode (thus disabling the preemption feature) on all the Backups, the Backup that becomes the Master following the disappearance of the Master continues to be the Master. The new Master is not preempted.

NOTE

In VRRP, regardless of the setting for the preempt parameter, the Owner always becomes the Master again when it comes back online.

To disable preemption on a Backup, enter commands such as the following.

```
Brocade Router1(config)#interface ethernet 1/6
Brocade Router1(config-if-1/6)#ip vrrp vrid 1
Brocade Router1(config-if-1/6-vrid-1)#non-preempt-mode
```

Syntax: [no] non-preempt-mode

The syntax is the same for VRRP and VRRP-E.

Changing the timer scale

NOTE

Changing the timer scale is supported for IPv4 VRRP v2, IPv4 VRRP-E v2, and IPv6 VRRP-E v3. It is not supported for IPv6 VRRP v3.

To achieve sub-second failover times, you can shorten the duration of all scale timers for VSRP, VRRP, and VRRP-E by adjusting the timer scale. The timer scale is a value used by the software to calculate the timers. By default, the scale value is 1. If you increase the timer scale, each timer's value is divided by the scale value. Using the timer scale to adjust timer values enables you to easily change all the timers while preserving the ratios among their values. [Table 277](#) shows timer scale values.

TABLE 277 Time scale values

Timer	Timer scale	Timer value
Hello interval	1	1 second
	2	0.5 seconds
Dead interval	1	3 seconds
	2	1.5 seconds

TABLE 277 Time scale values (Continued)

Timer	Timer scale	Timer value
Backup Hello interval	1	60 seconds
	2	30 seconds
Hold-down interval	1	2 seconds
	2	1 second

If you configure the device to receive its timer values from the Master, the Backup also receives the timer scale value from the Master.

To change the timer scale, enter a command such as the following at the global CONFIG level of the CLI.

```
Brocade(config)# scale-timer 2
```

This command changes the scale to 2. All VSRP, VRRP, and VRRP-E timer values will be divided by 2.

Syntax: **[no] scale-timer** <num>

The <num> variable specifies the multiplier. You can specify a timer scale from 1 through 10. However, Brocade recommends the timer scale of 1 or 2 for VRRP and VRRP-E.

NOTE

Be cautious when configuring the **scale-timer** command in a VRRP or VRRP-E scaled environment. VSRP, VRRP, and VRRP-E are time-sensitive protocols and system behavior cannot be predicted when the timers are scaled.

VRRP-E slow start timer

In a VRRP-E configuration, if a Master router goes down, the Backup router with the highest priority takes over after expiration of the dead interval. When the original Master router comes back up again, it takes over from the Backup router (which became the Master router when the original Master router went down). By default, this transition from Backup back to Master takes place immediately. However, you can configure the VRRP-E slow start timer feature, which causes a specified amount of time to elapse between the time the Master is restored and when it takes over from the Backup. This interval allows time for OSPF convergence when the Master is restored.

To set the IPv4 VRRP-E slow start timer to 30 seconds, enter the following commands.

```
Brocade(config)#router vrrp-extended
Brocade(config-VRRP-E-router)#slow-start 30
```

To set the IPv6 VRRP-E slow start timer to 60 seconds, enter the following commands.

```
Brocade(config)#ipv6 router vrrp-extended
Brocade(config-ipv6-VRRP-E-router)#slow-start 60
```

Syntax: **[no] slow-start** <seconds>

The <seconds> variable specifies a value from 1 through 255.

If the Master subsequently comes back up again, the amount of time specified by the VRRP-E slow start timer elapses (in the IPv4 example, 30 seconds) before the Master takes over from the Backup.

The VRRP-E slow start timer is effective only if the VRRP-E Backup router detects another VRRP-E Master (Standby) router. It is not effective during the initial bootup. The slow start timer is effective on a Backup router if the priority of the Backup router is equal to the configured priority on the Backup state router.

NOTE

The VRRP-E slow start timer applies only to VRRP-E configurations. It does not apply to VRRP configurations.

VRRP-E Extension for Server Virtualization

VRRP-E is enhanced with the VRRP-E Extension for Server Virtualization feature so that the Brocade device attempts to bypass the VRRP-E Master router and directly forward packets to their destinations through interfaces on the Backup router.

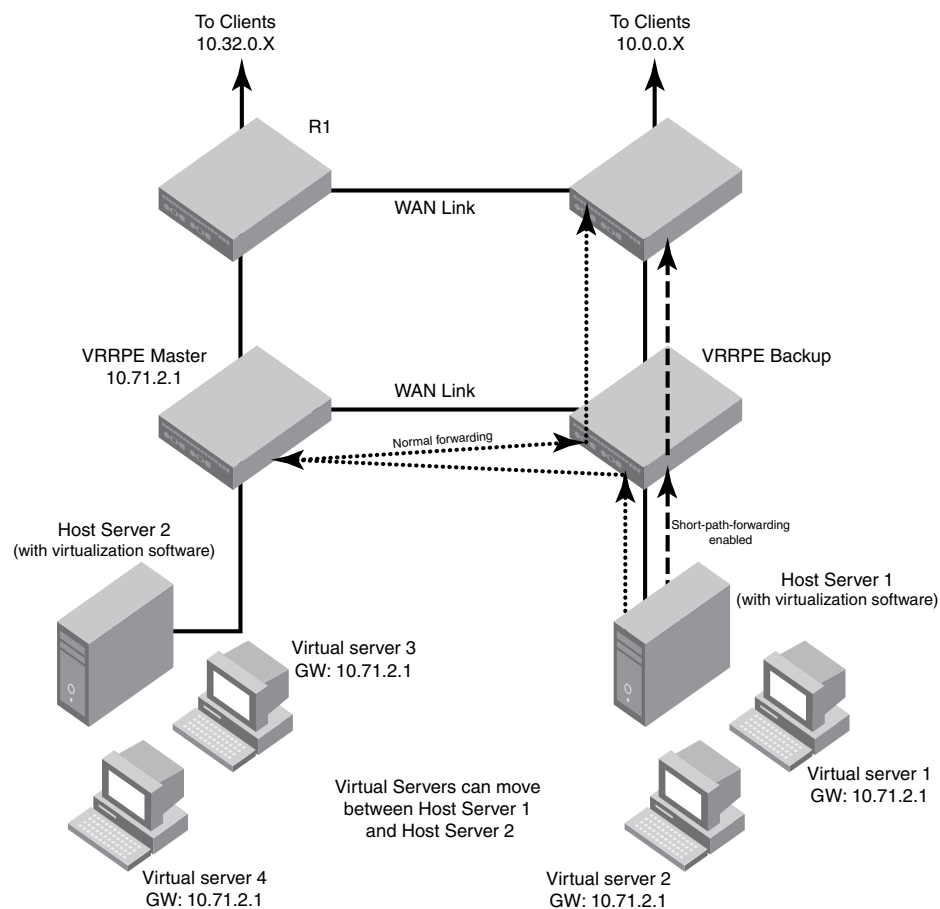

[Figure 187](#) shows an example of VRRP-E Extension for Server Virtualization. As shown, the virtual servers are dynamically moved between Host Server 1 and Host Server 2. Each time the virtual server is activated, it can be on a different Host Server, and sometimes the traffic crosses the WAN two times before it reaches the client. For example, in the VRRP-E implementation (without VRRP-E Extension for Server Virtualization), traffic from Virtual server 1 to the client at 10.0.0.X was switched to the VRRP-E Master router, then routed back to the VRRP-E Backup router, and then routed to the client (the normal forwarding path).

Short-path forwarding limitation

- Short-path forwarding (SPF) applies to IPv4 on Brocade FESX, FSX 800, and FSX 1600 platforms only. SPF is not supported on Brocade FWS, FCX, or ICX platforms.

Short-path forwarding configuration notes

- The VRRP-E Master router and Backup router must have routes to all destinations. You should utilize dynamic routing protocols such as Open Shortest Path First (OSPF) on all routers; otherwise, you must configure the static routes.
- Although it is not required, it is recommended that interfaces on different routers with the same VRID have the same SPF configuration. This ensures that the SPF behavior is retained after a failover. Different VRIDs, however, can have different SPF configurations.

FIGURE 187 VRRP-E Extension for short-path forwarding

VRRP-E Extension for short-path forwarding example

Under the VRRP-E VRID configuration level, there is an option to enable short-path forwarding. To enable short-path forwarding, enter the following commands.

```
Brocade (config)# router vrrp-extended
Brocade (config)# interface ve 10
Brocade (config-vif-10)# ip-address 10.10.10.25/24
Brocade (config-vif-10)# ip vrrp-extended vrid 10
Brocade (config-vif-10-vrid-10)# backup priority 50
Brocade (config-vif-10-vrid-10)# ip-address 10.10.10.254
Brocade (config-vif-10-vrid-10)# short-path-forwarding
Brocade (config-vif-10-vrid-10)# activate
```

Syntax: [no] short-path-forwarding [revert-priority <value>]

The **revert-priority** <value> parameter uses the priority value as the threshold to determine whether the short-path forwarding (SPF) behavior is effective. Typically, when short-path forwarding is enabled, the Backup router enforces SPF. For each port that goes down, the current priority of the VRRP-E router is lowered by the number specified in the **track-port** command. When the current priority is lower than the threshold, the SPF behavior is temporarily suspended and reverts back to the pre-SPF VRRP-E forwarding behavior. The value range is from 1 through 255.

Displaying short-path forwarding combinations

When short-path forwarding (SPF) is configured, the output of the following show commands include the SPF information:

- **show run**
- **show ip vrrp-e brief**
- **show ip vrrp-e vrid <vrid>**

The following example displays information about VRID 1 when only short-path forwarding is configured.

```
Brocade# show ip vrrp-e vrid 1
VRID 1
  Interface ethernet v100
  state backup
  administrative-status enabled
  priority 110
  current priority 90
  hello-interval 1000 msec
  dead-interval 0 msec
  current dead-interval 3500 msec
  preempt-mode true
  virtual ip address 100.1.1.3
  virtual mac address 02e0.5289.7001
  advertise backup: disabled
  master router 100.1.1.1 expires in 00:00:02.6
  track-port 1/13(down)
  short-path-forwarding enabled
```

The following example displays information about VRID 1 when short-path forwarding and revert-priority are configured.

```
Brocade# show ip vrrp-e vrid 1
VRID 1
  Interface ethernet v100
  state backup
  administrative-status enabled
  priority 110
  current priority 90
  hello-interval 1000 msec
  dead-interval 0 msec
  current dead-interval 3500 msec
  preempt-mode true
  virtual ip address 100.1.1.3
  virtual mac address 02e0.5289.7001
  advertise backup: disabled
  master router 100.1.1.1 expires in 00:00:02.7
  track-port 1/13(down)
  short-path-forwarding enabled <revertible priority 80 not reverted >
```

Forcing a Master router to abdicate to a Backup router

NOTE

Forcing a Master router to abdicate to a Backup router is not supported for IPv6 VRRP, IPv4 VRRP-E, and IPv6 VRRP-E. It is only supported for IPv4 VRRP.

You can force a VRRP Master to abdicate (give away control) of a VRID to a Backup router by temporarily changing the Master priority to a value less than that of the Backup router.

The VRRP Owner always has priority 255. You can use this feature to temporarily change the Owner priority to a value from 1 through 254.

NOTE

When you change the VRRP Owner priority, the change takes effect only for the current power cycle. The change is not saved to the startup-config file when you save the configuration and is not retained across a reload or reboot. Following a reload or reboot, the VRRP Owner again has priority 255.

To change the Master priority, enter commands such as the following.

```
Brocade(config)# interface ethernet 1/6
Brocade(config-if-1/6)# ip vrrp vrid 1
Brocade(config-if-1/6-vrid-1)# owner priority 99
```

Syntax: [no] owner priority <num>

The <num> variable specifies the new priority and can be a number from 1 through 254.

When the command is enabled, the software changes the priority of the Master to the specified priority. If the new priority is lower than at least one Backup priority for the same VRID, the Backup router takes over and becomes the new Master until the next software reload or system reset.

To verify the change, enter the following command from any level of the CLI.

```
Brocade#show ip vrrp
Total number of VRRP routers defined: 1
Interface ethernet v3
auth-type simple text password
VRID 3
  state backup
  administrative-status enabled
  mode non-owner(backup)
  priority 110
  current priority 110
  hello-interval 1000 msec
  dead-interval 0 msec
  current dead-interval 3500 msec
  preempt-mode true
  ip-address 172.21.3.1
  virtual mac address 0000.5e00.0103
  advertise backup: enabled
  next hello sent in 00:00:26.1
  master router 172.21.3.1 expires in 00:00:02.7
```

This example shows that even though this Layer 3 switch is the Owner of the VRID (“mode owner”), the Layer 3 switch priority for the VRID is 110 and the state is now “backup” instead of “active”. In addition, the administrative status is “enabled”.

To change the Master priority back to the default Owner priority 255, enter **no** followed by the command you entered to change the priority. For example, to change the priority of a VRRP Owner back to 255 from 110, enter the following command.

```
Brocade(config-if-1/6-vrid-1)#no owner priority 110
```

You cannot set the priority to 255 using the **owner priority** command.

Displaying VRRP and VRRP-E information

You can display the following information for VRRP or VRRP-E:

- Summary configuration and status information
- Detailed configuration and status information
- VRRP and VRRP-E statistics
- CPU utilization statistics

Displaying summary information

To display summary information for a Layer 3 switch for VRRP, enter the **show ip vrrp brief** command at any level of the CLI.

```
Brocade#show ip vrrp brief
```

```
Total number of VRRP routers defined: 1
Interface VRID CurPri P State Master addr Backup addr VIP
1/6          1    255 P Init  192.53.5.1  192.53.5.3 192.53.5.1
```

To display summary information for IPv6 VRRP, enter the **show ipv6 vrrp brief** command at any level of the CLI.

```
Brocade#show ipv6 vrrp brief
```

```
Total number of VRRP routers defined: 1
Interface      VRID CurPri P State Master addr
Backup addr
VIP
1/5            1    255 P Master Master addr: Local
Backup addr: fe80::212:f2ff:fea8:3900
VIP           : 2001::1
```

To display summary information for IPv6 VRRP-E v3 , enter the **show ipv6 vrrp-extended brief** command at any level of the CLI.

```
Brocade#show ipv6 vrrp-extended brief
Total number of VRRP-Extended routers defined: 3
Interface      VRID CurPri P State Master addr
                Backup addr
                VIP
1/1/1          1    100   P Master Master addr: Local
                Backup addr: fe80::212:f2ff:fea8:5b00
                VIP      : 2000:1::100
1/1/2          2    150   P Master Master addr: Local
                Backup addr: fe80::212:f2ff:fea8:5b00
                VIP      : 2000:2::100
v51            100  100   P Master Master addr: Local
                Backup addr: fe80::212:f2ff:fea8:5b00
                VIP      : 2000:51::100
```

Syntax for IPv4 VRRP v2 and IPv6 VRRP v3:

Syntax: **show ip vrrp brief** | **ethernet** [**<slotnum>/<portnum>**] | **ve** **<num>** | **stat** | **vrid** **<num>**

Syntax: **show ipv6 vrrp brief** | **ethernet** [**<slotnum>/<portnum>**] | **ve** **<num>** | **stat** | **vrid** **<num>**

Syntax for IPv4 VRRP-E v2 and IPv6 VRRP-E v3:

Syntax: **show ip vrrp-extended brief** | **ethernet** [**<slotnum>/<portnum>**] | **ve** **<num>** | **stat** | **vrid** **<num>**

Syntax: **show ipv6 vrrp-extended brief** | **ethernet** [**<slotnum>/<portnum>**] | **ve** **<num>** | **stat** | **vrid** **<num>**

The **brief** option displays the summary information. If you do not use this option, detailed information is displayed instead. Refer to [“Displaying detailed information”](#) on page 1686.

The **ethernet** **<slotnum>** option is required on chassis devices if you specify a port number.

The **ethernet** **<portnum>** option specifies an Ethernet port. If you use this option, the command displays VRRP or VRRP-E information only for the specified port.

The **ve** **<num>** option specifies a virtual interface. If you use this option, the command displays VRRP or VRRP-E information only for the specified virtual interface.

The **stat** option displays statistics. Refer to [“Displaying statistics”](#) on page 1692.

The **vrid** **<num>** option specifies the virtual router ID. Enter a value from 1 through 255.

[Table 278](#) shows a description of the output for the **show ip vrrp brief** and **show ip vrrp-extended brief** commands.

TABLE 278 CLI display of VRRP or VRRP-E summary information

Field	Description
Total number of VRRP (or VRRP-Extended) routers defined	The total number of VRIDs configured on this Layer 3 switch. NOTE: The total applies only to the protocol the Layer 3 switch is running. For example, if the Layer 3 switch is running VRRP-E, the total applies only to VRRP-E routers.
Interface	The interface on which VRRP or VRRP-E is configured. If VRRP or VRRP-E is configured on multiple interfaces, information for each interface is listed separately.

TABLE 278 CLI display of VRRP or VRRP-E summary information (Continued)

Field	Description
VRID	The VRID configured on this interface. If multiple VRIDs are configured on the interface, information for each VRID is listed in a separate row.
CurPri	The current VRRP or VRRP-E priority of this Layer 3 switch for the VRID.
P	Whether the backup preempt mode is enabled. If the backup preempt mode is enabled, this field contains a "P". If the mode is disabled, this field is blank.
State	<p>This Layer 3 switch VRRP or VRRP-E state for the VRID. The state can be one of the following:</p> <ul style="list-style-type: none"> Init – The VRID is not enabled (activated). If the state remains Init after you activate the VRID, make sure that the VRID is also configured on the other routers and that the routers can communicate with each other. <p>NOTE: If the state is Init and the mode is incomplete, make sure you have specified the IP address for the VRID.</p> <ul style="list-style-type: none"> Backup – This Layer 3 switch is a Backup for the VRID. Master – This Layer 3 switch is the Master for the VRID.
Master addr	IP address of the router interface that is currently Master for the VRID.
Backup addr	IP addresses of router interfaces that are currently Backups for the VRID.
VIP	The virtual IP address that is being backed up by the VRID.

Displaying detailed information

To display detailed VRRP or VRRP-E information, enter the **show ip vrrp** command at any level of the CLI.

```
Brocade#show ip vrrp

Total number of VRRP routers defined: 1
Interface ethernet v3
auth-type simple text password
VRID 3
  state master
  administrative-status enabled
  mode owner
  priority 255
  current priority 255
  track-priority 150
  hello-interval 1000 msec
  ip-address 172.21.3.1
  virtual mac address 0000.5e00.0103
  advertise backup: disabled
  next hello sent in 00:00:00.7
  backup router 172.21.3.2 expires in 00:02:41.3
  track-port 3/14(up)
```

The following example is for a VRRP Backup.

```
Brocade#show ip vrrp

Total number of VRRP routers defined: 1
Interface ethernet v3
auth-type simple text password
VRID 3
  state backup
  administrative-status enabled
  mode non-owner(backup)
  priority 110
  current priority 110
  hello-interval 1000 msec
  dead-interval 0 msec
  current dead-interval 3500 msec
  preempt-mode true
  ip-address 172.21.3.1
  virtual mac address 0000.5e00.0103
  advertise backup: enabled
  next hello sent in 00:00:26.1
  master router 172.21.3.1 expires in 00:00:02.7
  track-port 4/1-4/4(up)
```

The following example is for a VRRP-E Master.

```
Brocade#show ip vrrp-extended

Total number of VRRP-Extended routers defined: 50
Interface ethernet v201
auth-type simple text password
VRID 201
  state master
  administrative-status enabled
  priority 220
  current priority 220
  hello-interval 1000 msec
  dead-interval 0 msec
  current dead-interval 3100 msec
  preempt-mode true
  virtual ip address 201.201.201.5
  virtual mac address 02e0.52d7.82c9
  advertise backup: enabled
  next hello sent in 00:00:00.1
  backup router 201.201.201.4 expires in 00:02:45.2
  backup router 201.201.201.3 expires in 00:02:47.6
  track-port 1/1/25*2/1/24(up)
```

Syntax: `show ip vrrp brief | ethernet [<slotnum>]/<portnum> | ve <num> | stat`

Syntax: `show ip vrrp-extended brief | ethernet [<slotnum>]/<portnum> | ve <num> | stat`

The **brief** option displays summary information. Refer to [“Displaying summary information”](#) on page 1684.

The **ethernet <portnum>** option specifies an Ethernet port. If you use this option, the command displays VRRP or VRRP-E information only for the specified port. Also, you must specify the **<slotnum>** variable on chassis devices.

The **ve** <num> option specifies a virtual interface. If you use this option, the command displays VRRP or VRRP-E information only for the specified virtual interface.

The **stat** option displays statistics. Refer to “[Displaying statistics](#)” on page 1692.

[Table 279](#) shows a description of the output for the **show ip vrrp** and **show ip vrrp-extended** commands.

TABLE 279 CLI display of VRRP or VRRP-E detailed information

Field	Description
Total number of VRRP (or VRRP-Extended) routers defined	The total number of VRIDs configured on this Layer 3 switch. NOTE: The total applies only to the protocol the Layer 3 switch is running. For example, if the Layer 3 switch is running VRRP-E, the total applies only to VRRP-E routers.
Interface parameters	
Interface	The interface on which VRRP, VRRP v3, VRRP-E, or IPv6 VRRP-E is configured. If VRRP, VRRP v3, VRRP-E, or IPv6 VRRP-E is configured on multiple interfaces, information for each interface is listed separately.
auth-type	The authentication type enabled on the interface.
VRID parameters	
VRID	The VRID configured on this interface. If multiple VRIDs are configured on the interface, information for each VRID is listed separately.
state	This Layer 3 switch VRRP, VRRP v3, VRRP-E, or IPv6 VRRP-E state for the VRID. The state can be one of the following: <ul style="list-style-type: none"> initialize – The VRID is not enabled (activated). If the state remains “initialize” after you activate the VRID, make sure that the VRID is also configured on the other routers and that the routers can communicate with each other. NOTE: If the state is “initialize” and the mode is incomplete, make sure you have specified the IP address for the VRID. <ul style="list-style-type: none"> backup – This Layer 3 switch is a Backup for the VRID. master – This Layer 3 switch is the Master for the VRID.
administrative-status	The administrative status of the VRID. The administrative status can be one of the following: <ul style="list-style-type: none"> disabled – The VRID is configured on the interface but VRRP or VRRP-E has not been activated on the interface. enabled – VRRP, VRRP v3, VRRP-E, or IPv6 VRRP-E has been activated on the interface.
mode	Indicates whether the Layer 3 switch is the Owner or a Backup for the VRID. NOTE: If “incomplete” appears after the mode, configuration for this VRID is incomplete. For example, you might not have configured the virtual IP address that is being backed up by the VRID. NOTE: This field applies only to VRRP or VRRP v3. All Layer 3 switches configured for VRRP-E are Backups.
priority	The device preferability for becoming the Master for the VRID. During negotiation, the router with the highest priority becomes the Master. If two or more devices are tied with the highest priority, the Backup interface with the highest IP address becomes the active router for the VRID.

TABLE 279 CLI display of VRRP or VRRP-E detailed information (Continued)

Field	Description
current priority	<p>The current VRRP, VRRP v3, VRRP-E, or IPv6 VRRP-E priority of this Layer 3 switch for the VRID. The current priority can differ from the configured priority (refer to the priority field) for the following reason:</p> <p>The current priority can differ from the configured priority in the VRID if the VRID is configured with track ports and the link on a tracked interface has gone down. Refer to “Track ports and track priority” on page 1654.</p>
hello-interval	<p>The configured value for the Hello interval. This is the amount of time, in milliseconds, between Hello messages from the Master to the Backups for a given VRID.</p> <p>NOTE: In some VRRP command outputs, Hello interval timers are displayed in seconds instead of milliseconds.</p>
dead interval	<p>The configured value for the dead interval. This is the amount of time, in milliseconds, that a Backup waits for a Hello message from the Master for the VRID before determining that the Master is no longer active.</p> <p>If the Master does not send a Hello message before the dead interval expires, the Backups negotiate (compare priorities) to select a new Master for the VRID.</p> <p>NOTE: If the value is 0, then you have not configured this parameter.</p> <p>NOTE: This field does not apply to VRRP Owners.</p> <p>NOTE: All timer fields (Hello interval, dead interval, current dead interval, and so on) are displayed in milliseconds.</p>
current dead interval	<p>The current value of the dead interval. This value is equal to the value configured for the dead interval.</p> <p>If the value for the dead interval is not configured, then the current dead interval is equal to three times the Hello interval plus Skew time (where Skew time is equal to 256 minus priority divided by 256).</p> <p>NOTE: This field does not apply to VRRP Owners.</p>
preempt mode	<p>Whether the backup preempt mode is enabled.</p> <p>NOTE: This field does not apply to VRRP Owners.</p>
virtual ip address	The virtual IP addresses that this VRID is backing up. The address can be an IPv4 or IPv6 address.
virtual mac address	The virtual MAC addresses for the VRID. The MAC address can be an IPv4 or IPv6 address.
advertise backup	<p>The IP addresses of Backups that have advertised themselves to this Layer 3 switch by sending Hello messages.</p> <p>NOTE: Hello messages from Backups are disabled by default. You must enable the Hello messages on the Backup for the Backup to advertise itself to the current Master. Refer to “Hello messages” on page 1653.</p>
backup router <ip-addr> expires in <time>	<p>The IP addresses of Backups that have advertised themselves to this Master by sending Hello messages.</p> <p>The <time> value indicates how long before the Backup expires. A Backup expires if you disable the advertise backup option on the Backup or the Backup becomes unavailable. Otherwise, the Backup next Hello message arrives before the Backup expires. The Hello message resets the expiration timer.</p> <p>An expired Backup does not necessarily affect the Master. However, if you have not disabled the advertise backup option on the Backup, then the expiration may indicate a problem with the Backup.</p> <p>NOTE: This field applies only when Hello messages are enabled on the Backups (using the advertise backup option).</p>

TABLE 279 CLI display of VRRP or VRRP-E detailed information (Continued)

Field	Description
next hello sent in <time>	How long until the Backup sends its next Hello message. NOTE: This field applies only when this Layer 3 switch is the Master and the Backup is configured to send Hello messages (the advertise backup option is enabled).
master router <ip-addr> expires in <time>	The IP address of the Master and the amount of time until the Master dead interval expires. If the Backup does not receive a Hello message from the Master by the time the interval expires, either the IP address listed for the Master will change to the IP address of the new Master, or this Layer 3 switch itself will become the Master. NOTE: This field applies only when this Layer 3 switch is a Backup.
track port	The interfaces that the VRID interface is tracking. If the link for a tracked interface goes down, the VRRP, VRRP v3, VRRP-E, or IPv6 VRRP-E priority of the VRID interface is changed, causing the devices to renegotiate for Master. NOTE: This field is displayed only if track interfaces are configured for this VRID.

Displaying detailed information for an individual VRID

You can display information about the settings configured for a specified VRRP Virtual Router ID (VRID). To display information about VRID 1, enter the **show ip vrrp vrid** command.

```
Brocade#show ip vrrp vrid 2
VRID 2
  Interface ethernet v2
  state master
  administrative-status enabled
  version v2
  mode non-owner(backup)
  priority 100
  current priority 100
  hello-interval 1000 msec
  dead-interval 0 msec
  current dead-interval 3600 msec
  preempt-mode true
  ip-address 1.1.1.5
  virtual mac address 0000.5e00.0102
  advertise backup: disabled
  next hello sent in 00:00:01.0
```

To display information about the settings configured for a specified IPv6 VRRP VRID, enter the **show ipv6 vrrp vrid** command.

```

Brocade#show ipv6 vrrp vrid 1
VRID 1
  Interface ethernet 5
  state backup
  administrative-status enabled
  version v3
  mode non-owner(backup)
  priority 100
  current priority 100
  hello-interval 1000 msec
  dead-interval 0 msec
  current dead-interval 3000 msec
  preempt-mode true
  ip-address a7a7:a7a7:a7a7::1
  virtual mac address 0000.5e00.0201
  advertise backup: enabled

```

Syntax: `show ip vrrp vrid <num> [ethernet <num> | ve <num>]`

Syntax: `show ipv6 vrrp vrid <num> [ethernet <num> | ve <num>]`

The `<num>` variable specifies the VRID.

The `ethernet <num> | ve <num>` options specify an interface on which the VRID is configured. If you specify an interface, VRID information is displayed for that interface only. Otherwise, information is displayed for all the interfaces on which the specified VRID is configured.

[Table 280](#) shows a description of the output for the `show ip vrrp vrid` command.

TABLE 280 Output from the `show ip vrrp vrid` command

Field	Description
VRID	The specified VRID.
Interface	The interface on which VRRP is configured.
State	<p>This Layer 3 switch VRRP state for the VRID. The state can be one of the following:</p> <ul style="list-style-type: none"> Init – The VRID is not enabled (activated). If the state remains Init after you activate the VRID, make sure that the VRID is also configured on the other routers and that the routers can communicate with each other. <p>NOTE: If the state is Init and the mode is incomplete, make sure you have specified the IP address for the VRID.</p> <ul style="list-style-type: none"> Backup – This Layer 3 switch is a Backup for the VRID. Master – This Layer 3 switch is the Master for the VRID.
priority	The configured VRRP priority of this Layer 3 switch for the VRID.
current priority	The current VRRP priority of this Layer 3 switch for the VRID.
track priority	The new VRRP priority that the router receives for this VRID if the interface goes down.
hello interval	How often the Master router sends Hello messages to the Backups.
dead interval	The amount of time a Backup waits for a Hello message from the Master before determining that the Master is dead.

TABLE 280 Output from the show ip vrrp vrid command (Continued)

Field	Description
current dead interval	The current value of the dead interval. This value is equal to the value configured for the dead interval. If the value for the dead interval is not configured, then the current dead interval is equal to three times the Hello interval plus Skew time (where Skew time is equal to 256 minus priority divided by 256). NOTE: This field does not apply to VRRP Owners.
preempt mode	Whether the backup preempt mode is enabled. If the backup preempt mode is enabled, this field contains "true". If the mode is disabled, this field contains "false".
advertise backup	Whether Backup routers send Hello messages to the Master.

Displaying statistics

To display statistics on most Brocade devices, enter the **show ip vrrp stat** command at any level of the CLI.

```
Brocade#show ip vrrp stat
```

```
Interface ethernet 1/5
  rxd vrrp header error count = 0
  rxd vrrp auth error count = 0
  rxd vrrp auth passwd mismatch error count = 0
  rxd vrrp vrid not found error count = 0
VRID 1
  rxd arp packet drop count = 0
  rxd ip packet drop count = 0
  rxd vrrp port mismatch count = 0
  rxd vrrp ip address mismatch count = 0
  rxd vrrp hello interval mismatch count = 0
  rxd vrrp priority zero from master count = 0
  rxd vrrp higher priority count = 0
  transitioned to master state count = 1
  transitioned to backup state count = 1
```

To display IPv6 VRRP-E v3 statistics on a device, enter the following command at any level of the CLI.

```
Brocade#show ipv6 vrrp-extended stat ve 51
Interface ethernet v51
  rxd vrrp header error count = 0
  rxd vrrp auth error count = 0
  rxd vrrp auth passwd mismatch error count = 0
  rxd vrrp vrid not found error count = 0
VRID 100
  rxd arp packet drop count = 0
  rxd ip packet drop count = 0
  rxd vrrp port mismatch count = 0
  rxd vrrp ip address mismatch count = 0
  rxd vrrp hello interval mismatch count = 0
  rxd vrrp priority zero from master count = 0
  rxd vrrp higher priority count = 0
```

Table 281 shows a description of the output for the **show ip vrrp stat** and **show ip vrrp-extended stat** commands.

TABLE 281 CLI display of VRRP or VRRP-E statistics

Field	Description
Interface statistics	
Interface	The interface on which VRRP or VRRP-E is configured. If VRRP or VRRP-E is configured on more than one interface, the display lists the statistics separately for each interface.
rxed vrrp header error count	The number of VRRP or VRRP-E packets received by the interface that had a header error.
rxed vrrp auth error count	The number of VRRP or VRRP-E packets received by the interface that had an authentication error.
rxed vrrp auth passwd mismatch error count	The number of VRRP or VRRP-E packets received by the interface that had a password value that does not match the password used by the interface for authentication.
rxed vrrp vrid not found error count	The number of VRRP or VRRP-E packets received by the interface that contained a VRID that is not configured on this interface.
VRID statistics	
rxed arp packet drop count	The number of ARP packets addressed to the VRID that were dropped.
rxed ip packet drop count	The number of IP packets addressed to the VRID that were dropped.
rxed vrrp port mismatch count	The number of packets received that did not match the configuration for the receiving interface.
rxed vrrp ip address mismatch count	The number of packets received that did not match the configured IP addresses.
rxed vrrp hello interval mismatch count	The number of packets received that did not match the configured Hello interval.
rxed vrrp priority zero from master count	Indicates that the current Master has resigned.
rxed vrrp higher priority count	The number of VRRP or VRRP-E packets received by the interface that had a higher backup priority for the VRID than this Layer 3 switch backup priority for the VRID.
transitioned to master state count	The number of times this Layer 3 switch has changed from the backup state to the master state for the VRID.
transitioned to backup state count	The number of times this Layer 3 switch has changed from the master state to the backup state for the VRID.

Clearing VRRP or VRRP-E statistics

To clear VRRP or VRRP-E statistics, enter the **clear ip vrrp-stat** command at the Privileged EXEC level or any configuration level of the CLI.

```
Brocade#clear ip vrrp-stat
```

Syntax: clear ip vrrp-stat

To clear IPv6 VRRP v3 or IPv6 VRRP-E v3 statistics, enter the following command at the Privileged EXEC level or any configuration level of the CLI.

```
Brocade#clear ipv6 vrrp-stat
```

Syntax: clear ipv6 vrrp-stat

Displaying CPU utilization statistics

To display CPU utilization statistics for the previous one-second, one-minute, five-minute, and fifteen-minute intervals, enter the following command at any level of the CLI. In the following output example, IPv6 protocols are also displayed.

```
Brocade#show process cpu
```

Process Name	5Sec(%)	1Min(%)	5Min(%)	15Min(%)	Runtime(ms)
ARP	0.02	0.02	0.02	0.02	15532
BGP	0.00	0.00	0.00	0.00	0
DOT1X	0.00	0.00	0.00	0.00	0
GVRP	0.00	0.00	0.00	0.00	0
ICMP	0.01	0.01	0.01	0.01	8608
IP	0.09	0.12	0.11	0.08	72959
OSPF	0.05	0.07	0.07	0.06	85015
RIP	0.00	0.00	0.00	0.00	98
STP	0.68	0.86	0.78	0.57	568586
VRRP	0.42	0.54	0.50	0.37	357133

Process Name	5Sec(%)	1Min(%)	5Min(%)	15Min(%)	Runtime(ms)
IPv6	1.23	1.49	0.99	1.40	917973
ICMP6	0.04	0.05	0.06	0.04	38508
ND6	0.00	0.01	0.01	0.01	6691
RIPng	0.00	0.00	0.00	0.00	45
OSPFv3	0.00	0.00	0.00	0.00	1515
IPV6_RX	0.16	0.21	0.21	0.14	143506

If the software has been running less than 15 minutes (the maximum interval for utilization statistics), the command indicates how long the software has been running, as shown in the following example.

```
Brocade#show process cpu
```

The system has only been up for 6 seconds.

Process Name	5Sec(%)	1Min(%)	5Min(%)	15Min(%)	Runtime(ms)
ARP	0.01	0.00	0.00	0.00	0
BGP	0.00	0.00	0.00	0.00	0
GVRP	0.00	0.00	0.00	0.00	0
ICMP	0.01	0.00	0.00	0.00	1
IP	0.00	0.00	0.00	0.00	0
OSPF	0.00	0.00	0.00	0.00	0
RIP	0.00	0.00	0.00	0.00	0
STP	0.00	0.00	0.00	0.00	0
VRRP	0.00	0.00	0.00	0.00	0

To display utilization statistics for a specific number of seconds, enter a command such as the following. In the following output example, IPv6 protocols are also displayed for a specific number of seconds.

```
Brocade#show process cpu 2
```

Statistics for last 1 sec and 999 ms

Process Name	Sec(%)	Time(ms)
ARP	0.01	0
BGP	0.00	0
DOT1X	0.00	0
GVRP	0.00	0
ICMP	0.01	0
IP	0.04	0
OSPF	0.07	1
RIP	0.00	0
STP	0.97	19
VRRP	0.53	10

Statistics for last 1 sec and 999 ms

Process Name	Sec(%)	Time(ms)
IPv6	0.09	1
ICMP6	0.05	1
ND6	0.00	0
RIPng	0.00	0
OSPFv3	0.00	0
IPV6_RX	0.04	0

When you specify how many seconds of statistics you want to display, the software selects the sample that most closely matches the number of seconds you specified. In this example, statistics are requested for the previous two seconds. The closest sample available is for the previous 1 second plus 80 milliseconds.

Syntax: `show process cpu [<num>]`

The `<num>` variable specifies the number of seconds and can be a value from 1 through 900. If you use this variable, the command lists the usage statistics only for the specified number of seconds. If you do not use this variable, the command lists the usage statistics for the previous one-second, one-minute, five-minute, and fifteen-minute intervals.

Displaying VRRP and VRRP-E information for IPv6

You can display information for IPv6 VRRP or VRRP-E v3.

Displaying detailed information for IPv6 VRRP v3 and IPv6 VRRP-E v3

To display information for an IPv6 VRRP Owner, enter the **show ipv6 vrrp** command at any level of the CLI.

```
Brocade#show ipv6 vrrp
Total number of VRRP routers defined: 25
Interface ethernet v52
auth-type no authentication
VRID 52
  state master
  administrative-status enabled
  version v3
  mode owner
  priority 255
  current priority 255
  track-priority 5
  hello-interval 1000 msec
  ipv6-address 2172:52::52:3
  virtual mac address 0000.5e00.0234
  advertise backup: disabled
  next hello sent in 00:00:00.1
  backup router fe80::224:38ff:fec8:5a40 expires in 00:02:03.1
```

To display information for an IPv6 VRRP Backup, enter the **show ipv6 vrrp** command at any level of the CLI.

```
Brocade#show ipv6 vrrp
Total number of VRRP routers defined: 26
Interface ethernet v52
auth-type no authentication
VRID 52
  state backup
  administrative-status enabled
  version v3
  mode non-owner(backup)
  priority 101
  current priority 20
  track-priority 20
  hello-interval 100 msec
  dead-interval 0 msec
  current dead-interval 300 msec
  preempt-mode true
  ipv6-address 2172:52::52:3
  virtual mac address 0000.5e00.0234
  advertise backup: enabled
  next hello sent in 00:00:36.5
  master router fe80::768e:f8ff:fe33:8600 expires in 00:00:00.2
  track-port 2/1/3*4/1/4(down) v41(up)
```

Syntax: `show ipv6 vrrp brief | ethernet <stack-unit>/<slotnum>/<portnum> | stat [ethernet <stack-unit>/<slotnum>/<portnum> | ve <num>] | vrid <num>`

To display detailed information for IPv6 VRRP-E, enter the `show ipv6 vrrp-extended` command at any level of the CLI.

```
Brocade#show ipv6 vrrp-extended
Total number of VRRP-Extended routers defined: 1
Interface ethernet v201
auth-type md5 authentication
VRID 201
  state master
  administrative-status enabled
  priority 100
  current priority 100
  hello-interval 1000 msec
  dead-interval 0 msec
  current dead-interval 3600 msec
  preempt-mode true
  virtual ipv6 address 2201:201::201:5
  virtual mac address 02e0.5202.bac9
  advertise backup: enabled
  next hello sent in 00:00:01.0
```

Syntax: `show ipv6 vrrp-extended brief | ethernet <stack-unit>/<slotnum>/<portnum> | stat [ethernet <stack-unit>/<slotnum>/<portnum> | ve <num>] | vrid <num>`

For more information on the field descriptions for the `show ipv6 vrrp` command and the `show ipv6 vrrp-extended` command, refer to [“CLI display of VRRP or VRRP-E detailed information”](#) on page 1688.

Configuration examples

The following sections contain the CLI commands for implementing the VRRP and VRRP-E configurations shown in [Figure 185](#) on page 1651 and [Figure 186](#) on page 1657.

VRRP example

To implement the VRRP configuration shown in [Figure 185](#) on page 1651, use the following method.

Configuring Switch 1

To configure VRRP Switch 1, enter the following commands.

```
Brocade Switch1(config)#switch vrrp
Brocade Switch1(config)#interface ethernet 1/6
Brocade Switch1(config-if-1/6)#ip-address 192.53.5.1
Brocade Switch1(config-if-1/6)#ip vrrp vrid 1
Brocade Switch1(config-if-1/6-vrid-1)#owner track-priority 20
Brocade Switch1(config-if-1/6-vrid-1)#track-port ethernet 2/4
Brocade Switch1(config-if-1/6-vrid-1)#ip-address 192.53.5.1
Brocade Switch1(config-if-1/6-vrid-1)#activate
```

NOTE

When you configure the Master (Owner), the address you enter with the **ip-address** command must already be configured on the interface.

Configuring Switch 2

To configure Switch 2 in [Figure 185](#) on page 1651 after enabling VRRP, enter the following commands.

```
Brocade Switch2(config)#switch vrrp
Brocade Switch2(config)#interface ethernet 1/5
Brocade Switch2(config-if-1/5)#ip-address 192.53.5.3
Brocade Switch2(config-if-1/5)#ip vrrp vrid 1
Brocade Switch2(config-if-1/5-vrid-1)#backup priority 100 track-priority 19
Brocade Switch2(config-if-1/5-vrid-1)#track-port ethernet 3/2
Brocade Switch2(config-if-1/5-vrid-1)#ip-address 192.53.5.1
Brocade Switch2(config-if-1/5-vrid-1)#activate
```

The **backup** command specifies that this router is a VRRP Backup for virtual router VRID1. The IP address entered with the **ip-address** command is the same IP address as the one entered when configuring Switch 1. In this case, the IP address cannot also exist on Switch 2, but the interface on which you are configuring the VRID Backup must have an IP address in the same subnet. By entering the same IP address as the one associated with this VRID on the Owner, you are configuring the Backup to back up the address, but you are not duplicating the address.

NOTE

When you configure a Backup router, the router interface on which you are configuring the VRID must have a real IP address that is in the same subnet as the address associated with the VRID by the Owner. However, the address cannot be the same.

The **priority** parameter establishes the router VRRP priority in relation to the other VRRP routers in this virtual router. The **track-priority** parameter specifies the new VRRP priority that the router receives for this VRID if the interface goes down. Refer to [“Track ports and track priority”](#) on page 1654.

The **activate** command activates the VRID configuration on this interface. The interface does not provide backup service for the virtual IP address until you activate the VRRP configuration. Alternatively, you can use the **enable** command. The **activate** and **enable** commands do the same thing.

Syntax: router vrrp

Syntax: ip vrrp vrid <vrid>

Syntax: owner [track-priority <value>]

Syntax: backup [priority <value>] [track-priority <value>]

Syntax: track-port ethernet [<slotnum>/]<portnum> | ve <num>

Syntax: ip-address <ip-addr>

Syntax: activate

VRRP-E example

To implement the VRRP-E configuration shown in [Figure 186](#) on page 1657, use the following CLI method.

Configuring Switch 1

To configure VRRP Switch 1 in [Figure 186](#) on page 1657, enter the following commands.

```
Brocade Switch1(config)#switch vrrp-extended
Brocade Switch1(config)#interface ethernet 1/6
Brocade Switch1(config-if-1/6)#ip-address 192.53.5.2/24
Brocade Switch1(config-if-1/6)#ip vrrp-extended vrid 1
Brocade Switch1(config-if-1/6-vrid-1)#backup priority 110 track-priority 20
Brocade Switch1(config-if-1/6-vrid-1)#track-port ethernet 2/4
Brocade Switch1(config-if-1/6-vrid-1)#ip-address 192.53.5.254
Brocade Switch1(config-if-1/6-vrid-1)#activate
VRRP Switch 1 for this interface is activating
Brocade Switch1(config-if-1/6-vrid-1)#exit
Brocade Switch1(config)#interface ethernet 1/6
Brocade Switch1(config-if-1/6)#ip vrrp-extended vrid 2
Brocade Switch1(config-if-1/6-vrid-1)#backup priority 100 track-priority 20
Brocade Switch1(config-if-1/6-vrid-1)#track-port ethernet 2/4
Brocade Switch1(config-if-1/6-vrid-1)#ip-address 192.53.5.253
Brocade Switch1(config-if-1/6-vrid-1)#activate
VRRP Switch 1 for this interface is activating
```

NOTE

The address you enter with the **ip-address** command cannot be the same as a real IP address configured on the interface.

Configuring Switch 2

To configure Switch 2, enter the following commands.

```
Brocade Switch2(config)#switch vrrp-extended
Brocade Switch2(config)#interface ethernet 5/1
Brocade Switch2(config-if-5/1)#ip-address 192.53.5.3/24
Brocade Switch2(config-if-5/1)#ip vrrp-extended vrid 1
Brocade Switch2(config-if-5/1-vrid-1)#backup priority 100 track-priority 20
Brocade Switch2(config-if-5/1-vrid-1)#track-port ethernet 3/2
Brocade Switch2(config-if-5/1-vrid-1)#ip-address 192.53.5.254
Brocade Switch2(config-if-5/1-vrid-1)#activate
VRRP Switch 2 for this interface is activating
```

```

Brocade Switch2(config-if-5/1-vrid-1)#exit
Brocade Switch2(config)#interface ethernet 5/1
Brocade Switch2(config-if-5/1)#ip vrrp-extended vrid 2
Brocade Switch2(config-if-5/1-vrid-1)#backup priority 110 track-priority 20
Brocade Switch2(config-if-5/1-vrid-1)#track-port ethernet 2/4
Brocade Switch2(config-if-5/1-vrid-1)#ip-address 192.53.5.253
Brocade Switch2(config-if-5/1-vrid-1)#activate
VRRP Switch 2 for this interface is activating

```

The **backup** command specifies that this router is a VRRP-E Backup for virtual router VRID1. The IP address entered with the **ip-address** command is the same IP address as the one entered when configuring Switch 1. In this case, the IP address cannot also exist on Switch 2, but the interface on which you are configuring the VRID Backup must have an IP address in the same subnet. By entering the same IP address as the one associated with this VRID on the Owner, you are configuring the Backup to back up the address, but you are not duplicating the address.

NOTE

When you configure a Backup router, the router interface on which you are configuring the VRID must have a real IP address that is in the same subnet as the address associated with the VRID by the Owner. However, the address cannot be the same.

The **priority** parameter establishes the router VRRP-E priority in relation to the other VRRP-E routers in this virtual router. The **track-priority** parameter specifies the new VRRP-E priority that the router receives for this VRID if the interface goes down. Refer to [“Track ports and track priority”](#) on page 1654.

The **activate** command activates the VRID configuration on this interface. The interface does not provide backup service for the virtual IP address until you activate the VRRP-E configuration. Alternatively, you can use the **enable** command. The **activate** and **enable** commands do the same thing.

Syntax: router vrrp-extended

Syntax: ip vrrp-extended vrid <vrid>

Syntax: backup [priority <value>] [track-priority <value>]

Syntax: track-port ethernet [<slotnum>/]<portnum> | ve <num>

Syntax: ip-address <ip-addr>

Syntax: activate

Rule-Based IP ACLs

Table 282 and Table 283 list the individual Brocade FastIron switches and Access Control List (ACL) features they support. Table 282 lists the features supported on inbound traffic, while Table 283 lists the features supported on outbound traffic. These features are supported in the Layer 2, base Layer 3, edge Layer 3, and full Layer 3 software images, except where explicitly noted.

TABLE 282 Supported ACL features on inbound traffic

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
Hardware-based ACLs	Yes	Yes	Yes	Yes	Yes
Standard named and numbered ACLs	Yes	Yes	Yes	Yes	Yes
Extended named and numbered ACLs	Yes	Yes	Yes	Yes	Yes
User input preservation for ACL TCP/UDP port numbers	Yes	Yes	Yes	Yes	Yes
ACL comment text	Yes	Yes	Yes	Yes	Yes
ACL logging of denied packets	Yes	Yes	Yes	Yes	Yes
ACL logging with traffic rate limiting (to prevent CPU overload)	Yes To enable, configure a traffic conditioner.	Yes	Yes	Yes	Yes
Strict control of ACL filtering of fragmented packets	Yes	Yes	Yes	Yes	Yes
ACL support for switched traffic in the router image	Yes To enable, use the bridged-routed parameter..	Yes	Yes	Yes	ICX 6450 only This feature is enabled by default on FWS, FCX and ICX devices. There is no CLI command to enable or disable it.
ACL filtering based on VLAN membership or VE port membership	Yes	Yes	Yes	Yes	Yes
ACLs to filter ARP packets	No	Yes	No	No	No
Filtering on IP precedence and ToS value	Yes	Yes	Yes	Yes	Yes
Combined DSCP and internal marking in one ACL rule	Yes	No	No	No	No
QoS options for IP ACLs	Yes	Yes	Yes	Yes	Yes ¹
DSCP CoS mapping	Yes	No	No	No	No
Priority mapping using ACLs	Yes	Yes	Yes	Yes	Yes

TABLE 282 Supported ACL features on inbound traffic

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
Hardware usage statistics	Yes	Yes	Yes	Yes	Yes
Policy-based routing (PBR) (Supported in the full Layer 3 code only)	Yes	No	Yes	Yes	No

1. ICX 6430 devices have only four priority queues. See [“Queues for the ICX 6430 switch”](#) on page 1973 for more information.

TABLE 283 Supported ACL features on outbound traffic

Feature	FSX 800 FSX 1600 ¹	FESX	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
Hardware-based ACLs	Yes	No	No	Yes	Yes	Yes
Standard named and numbered ACLs	Yes	No	No	Yes	Yes	Yes
Extended named and numbered ACLs	Yes	No	No	Yes	Yes	Yes
User input preservation for ACL TCP/UDP port numbers	Yes	No	No	Yes	Yes	Yes
ACL comment text	Yes	No	No	Yes	Yes	Yes
ACL logging of denied packets	No	No	No	No	No	No
ACL logging with traffic rate limiting (to prevent CPU overload)	No	No	No	No	No	No
Strict control of ACL filtering of fragmented packets	Yes	No	No	Yes	Yes	Yes
ACL support for switched traffic in the router image	Yes	No	No	Yes	Yes	ICX 6450 only
This feature is enabled by default for outbound ACLs on platforms that support outbound ACL support. There is no CLI command to enable or disable it.						
ACL filtering based on VLAN membership or VE port membership	Not applicable for outbound traffic.					
ACLs to filter ARP packets	Not applicable for outbound traffic.					
Filtering on IP precedence and ToS value	Yes	No	No	Yes	Yes	Yes
Combined DSCP and internal marking in one ACL rule	Not applicable for outbound traffic, as DSCP CoS mapping is not supported.					
QoS options for IP ACLs ²	Yes	No	No	Yes	Yes	Yes
DSCP CoS mapping	DSCP CoS mapping is not supported for outgoing traffic.					
Priority mapping using ACLs	Internal priority marking is not supported for outgoing traffic.					
Hardware usage statistics	Yes	No	No	Yes	Yes	Yes
Policy-based routing (PBR) (Supported in the full Layer 3 code only)	Not applicable for outbound traffic					No

1. ACL features for outbound traffic are only supported on specific FastIron SX 800 & FastIron SX 1600 modules. Please check with your Brocade Support representative for details.
2. DSCP CoS mapping is not supported for outgoing traffic.

This chapter describes how Access Control Lists (ACLs) are implemented and configured in the Brocade devices.

NOTE

For information about IPv6 ACLs, refer to [Chapter 41, “IPv6 ACLs”](#).

ACL overview

Brocade devices support **rule-based ACLs** (sometimes called hardware-based ACLs), where the decisions to permit or deny packets are processed in hardware and all permitted packets are switched or routed in hardware. All denied packets are also dropped in hardware. In addition, FastIron FWS devices support inbound ACLs only. Outbound ACLs are not supported on those devices. FSX, FCX, and ICX devices support both inbound and outbound ACLs. The ACL features supported on inbound and outbound traffic are as listed in [Table 282](#) and [Table 283](#) respectively and discussed in more detail in the rest of this chapter.

NOTE

FastIron devices do not support flow-based ACLs.

Rule-based ACLs program the ACL entries you assign to an interface into Content Addressable Memory (CAM) space allocated for the ports. The ACLs are programmed into hardware at startup (or as new ACLs are entered and bound to ports). Devices that use rule-based ACLs program the ACLs into the CAM entries and use these entries to permit or deny packets in the hardware, without sending the packets to the CPU for processing.

Rule-based ACLs are supported on the following interface types:

- Gbps Ethernet ports
- 10 Gbps Ethernet ports
- Trunk groups
- Virtual routing interfaces

Types of IP ACLs

You can configure the following types of IP ACLs:

- **Standard** – Permits or denies packets based on source IP address. Valid standard ACL IDs are 1 – 99 or a character string.
- **Extended** – Permits or denies packets based on source and destination IP address and also based on IP protocol information. Valid extended ACL IDs are a number from 100 – 199 or a character string.

ACL IDs and entries

ACLs consist of ACL IDs and ACL entries:

- **ACL ID** – An ACL ID is a number from 1 – 99 (for a standard ACL) or 100 – 199 (for an extended ACL) or a character string. The ACL ID identifies a collection of individual ACL entries. When you apply ACL entries to an interface, you do so by applying the ACL ID that contains the ACL entries to the interface, instead of applying the individual entries to the interface. This makes applying large groups of access filters (ACL entries) to interfaces simple. Refer to [“Numbered and named ACLs”](#) on page 1706.

NOTE

This is different from IP access policies. If you use IP access policies, you apply the individual policies to interfaces.

- **ACL entry** – Also called an **ACL rule**, this is a filter command associated with an ACL ID. The maximum number of ACL rules you can configure is a system-wide parameter and depends on the device you are configuring. You can configure up to the maximum number of entries in any combination in different ACLs. For example, on a FESX switch, you can configure 4095 entries in one ACL, 2046 entries in two ACLs, etc.. The total number of entries in all ACLs cannot exceed the system maximum listed in [Table 284](#).

TABLE 284 Maximum number of ACL entries

System	Maximum ACL rules per port region	Maximum ACL entries per system
FESX Layer 2 Switch	IPv4 devices = 1016	4096
FESX Layer 3 Switch	IPv6 devices = 1023	
FSX 800 and FSX 1600 Layer 2 Switch	1015	8192
FSX 800 and FSX 1600 Layer 3 Switch		
FWS base Layer 3 Switch	756 (24-port) 1512 (48-port)	756 (24-port) 4096 (48-port)
FCX Layer 2 or Layer 3 Switch	4093	8192
ICX 6610	3069	8192
ICX 6430	508	8192
ICX 6450	3068	8192

You configure ACLs on a global basis, then apply them to the incoming or outgoing traffic on specific ports. The software applies the entries within an ACL in the order they appear in the ACL configuration. As soon as a match is found, the software takes the action specified in the ACL entry (permit or deny the packet) and stops further comparison for that packet.

Numbered and named ACLs

When you configure an ACL, you can refer to the ACL by a numeric ID or by an alphanumeric name. The commands to configure numbered ACLs are different from the commands for named ACLs.

- **Numbered ACL** – If you refer to the ACL by a numeric ID, you can use 1 – 99 for a standard ACL or 100 – 199 for an extended ACL.
- **Named ACL** – If you refer to the ACL by a name, you specify whether the ACL is a standard ACL or an extended ACL, then specify the name.

You can configure up to 99 standard numbered IP ACLs and 100 extended numbered IP ACLs. You also can configure up to 99 standard named ACLs and 100 extended named ACLs by number.

Default ACL action

The default action when no ACLs are configured on a device is to permit all traffic. However, once you configure an ACL and apply it to a port, the default action for that port is to deny all traffic that is not explicitly permitted on the port:

- If you want to tightly control access, configure ACLs consisting of permit entries for the access you want to permit. The ACLs implicitly deny all other access.
- If you want to secure access in environments with many users, you might want to configure ACLs that consist of explicit deny entries, then add an entry to permit all access to the end of each ACL. The software permits packets that are not denied by the deny entries.

How hardware-based ACLs work

When you bind an ACL to inbound or outbound traffic on an interface, the device programs the Layer 4 CAM with the ACL. Permit and deny rules are programmed. Most ACL rules require one Layer 4 CAM entry. However, ACL rules that match on more than one TCP or UDP application port may require several CAM entries. The Layer 4 CAM entries for ACLs do not age out. They remain in the CAM until you remove the ACL:

- If a packet received on the interface matches an ACL rule in the Layer 4 CAM, the device permits or denies the packet according to the ACL.
- If a packet does not match an ACL rule, the packet is dropped, since the default action on an interface that has ACLs is to deny the packet.

How fragmented packets are processed

The descriptions above apply to non-fragmented packets. The default processing of fragments by hardware-based ACLs is as follows:

- The first fragment of a packet is permitted or denied using the ACLs. The first fragment is handled the same way as non-fragmented packets, since the first fragment contains the Layer 4 source and destination application port numbers. The device uses the Layer 4 CAM entry if one is programmed, or applies the interface's ACL entries to the packet and permits or denies the packet according to the first matching ACL.
- For other fragments of the same packet, they are subject to a rule only if there is no Layer 4 information in the rule or in any preceding rules.

The fragments are forwarded even if the first fragment, which contains the Layer 4 information, was denied. Generally, denying the first fragment of a packet is sufficient, since a transaction cannot be completed without the entire packet.

On 48GC, 8x10GC, 2x10GC and 24GF modules, the first IP fragment packet is also treated as an IP packet fragment.

For tighter control, you can configure the port to drop all packet fragments. Refer to [“Enabling strict control of ACL filtering of fragmented packets”](#) on page 1732.

Hardware aging of Layer 4 CAM entries

Rule-based ACLs use Layer 4 CAM entries. The device permanently programs rule-based ACLs into the CAM. The entries never age out.

ACL configuration considerations

- See [“ACL overview”](#) on page 1705 for details on which devices support inbound and outbound ACLs.
- Hardware-based ACLs are supported on the following devices:
 - Gbps Ethernet ports
 - 10 Gbps Ethernet ports
 - Trunk groups
 - Virtual routing interfaces

NOTE

Brocade FCX devices do not support ACLs on Group VEs, even though the CLI contains commands for this action.

- Inbound ACLs apply to all traffic, including management traffic. By default outbound ACLs are not applied to traffic generated by the CPU. This must be enabled using the `enable egress-acl-on-control-traffic` command. See [“Applying egress ACLs to Control \(CPU\) traffic”](#) on page 1725 for details.
- The number of ACLs supported per device is listed in [Table 284](#).
- Hardware-based ACLs support only one ACL per port. The ACL of course can contain multiple entries (rules). For example, hardware-based ACLs do not support ACLs 101 and 102 on port 1, but hardware-based ACLs do support ACL 101 containing multiple entries.
- For devices that support both, inbound ACLs and outbound ACLs can co-exist. When an inbound ACL and an outbound ACL are configured on the same port, the outbound ACL is applied only on outgoing traffic.
- ACLs are affected by port regions. For example, on the FESX and FSX, multiple ACL groups share 1016 ACL rules per port region. Each ACL group must contain one entry for the implicit *deny all IP traffic* clause. Also, each ACL group uses a multiple of 8 ACL entries. For example, if all ACL groups contain 5 ACL entries, you could add 127 ACL groups (1016/8) in that port region. If all your ACL groups contain 8 ACL entries, you could add 63 ACL groups, since you must account for the implicit deny entry.
- By default, the first fragment of a fragmented packet received by the Brocade device is permitted or denied using the ACLs, but subsequent fragments of the same packet are forwarded in hardware. Generally, denying the first fragment of a packet is sufficient, since a transaction cannot be completed without the entire packet.
- ACLs are supported on member ports of a VLAN on which DHCP snooping and Dynamic ARP Inspection (DAI) are enabled. Also, IP source guard and ACLs are supported together on the same port, as long as both features are configured at the port-level or per-port-per-VLAN level. Brocade ports do not support IP source guard and ACLs on the same port if one is configured at the port-level and the other is configured at the per-port-per-VLAN level.
- Ingress MAC filters can be applied to the same port as an outbound ACL.

- A DOS attack configuration on a port will only apply on the ingress traffic.
- Outbound ACLs cannot be configured through a RADIUS server as dynamic or user-based ACLs. However, outbound ACLs can still be configured with MAC-AUTH/DOT1X enabled, as they the two are configured in different directions.
- The following ACL features and options are not supported on the FastIron devices:
 - Applying an ACL on a device that has Super Aggregated VLANs (SAVs) enabled.
 - ACL logging of permitted packets– ACL logging is supported for packets that are sent to the CPU for processing (denied packets) for inbound traffic. ACL logging is not supported for packets that are processed in hardware (permitted packets).
 - Flow-based ACLs
 - Layer 2 ACLs
- You can apply an ACL to a port that has TCP SYN protection or ICMP smurf protection, or both, enabled.

Configuring standard numbered ACLs

This section describes how to configure standard numbered ACLs with numeric IDs and provides configuration examples.

Standard ACLs permit or deny packets based on source IP address. You can configure up to 99 standard numbered ACLs. There is no limit to the number of ACL entries an ACL can contain except for the system-wide limitation. For the number of ACL entries supported on a device, refer to [“ACL IDs and entries”](#) on page 1706.

Standard numbered ACL syntax

Syntax: [no] access-list <ACL-num> deny | permit <source-ip> | <hostname> <wildcard> [log]

or

Syntax: [no] access-list <ACL-num> deny | permit <source-ip>/<mask-bits> | <hostname> [log]

Syntax: [no] access-list <ACL-num> deny | permit host <source-ip> | <hostname> [log]

Syntax: [no] access-list <ACL-num> deny | permit any [log]

Syntax: [no] ip access-group <ACL-num> in | out

The <ACL-num> parameter is the access list number from 1 – 99.

The **deny** | **permit** parameter indicates whether packets that match a policy in the access list are denied (dropped) or permitted (forwarded).

The <source-ip> parameter specifies the source IP address. Alternatively, you can specify the host name.

NOTE

To specify the host name instead of the IP address, the host name must be configured using the DNS resolver on the Brocade device. To configure the DNS resolver name, use the **ip dns server-address...** command at the global CONFIG level of the CLI.

The `<wildcard>` parameter specifies the mask value to compare against the host address specified by the `<source-ip>` parameter. The `<wildcard>` is in dotted-decimal notation (IP address format). It is a four-part value, where each part is 8 bits (one byte) separated by dots, and each bit is a one or a zero. Each part is a number ranging from 0 to 255, for example 0.0.0.255. Zeros in the mask mean the packet source address must match the `<source-ip>`. Ones mean any value matches. For example, the `<source-ip>` and `<wildcard>` values 209.157.22.26 0.0.0.255 mean that all hosts in the Class C subnet 209.157.22.x match the policy.

If you prefer to specify the wildcard (mask value) in CIDR format, you can enter a forward slash after the IP address, then enter the number of significant bits in the mask. For example, you can enter the CIDR equivalent of “209.157.22.26 0.0.0.255” as “209.157.22.26/24”. The CLI automatically converts the CIDR number into the appropriate ACL mask (where zeros instead of ones are the significant bits) and changes the non-significant portion of the IP address into ones. For example, if you specify 209.157.22.26/24 or 209.157.22.26 0.0.0.255, then save the changes to the startup-config file, the value appears as 209.157.22.0/24 (if you have enabled display of subnet lengths) or 209.157.22.0 0.0.0.255 in the startup-config file.

If you enable the software to display IP subnet masks in CIDR format, the mask is saved in the file in “/`<mask-bits>`” format. To enable the software to display the CIDR masks, enter the **ip show-subnet-length** command at the global CONFIG level of the CLI. You can use the CIDR format to configure the ACL entry regardless of whether the software is configured to display the masks in CIDR format.

NOTE

If you use the CIDR format, the ACL entries appear in this format in the running-config and startup-config files, but are shown with subnet mask in the display produced by the **show ip access-list** command.

The **host** `<source-ip> | <hostname>` parameter lets you specify a host IP address or name. When you use this parameter, you do not need to specify the mask. A mask of all zeros (0.0.0.0) is implied.

The **any** parameter configures the policy to match on all host addresses.

The **log** argument configures the device to generate Syslog entries and SNMP traps for inbound packets that are denied by the access policy.

The **in | out** parameter applies the ACL to incoming or outgoing traffic on the interface to which you apply the ACL. You can apply the ACL to an Ethernet port, or virtual interface.

NOTE

If the ACL is for a virtual routing interface, you also can specify a subset of ports within the VLAN containing that interface when assigning an ACL to the interface.

Configuration example for standard numbered ACLs

To configure a standard ACL and apply it to incoming traffic on port 1/1, enter the following commands.

```
Brocade(config)#access-list 1 deny host 209.157.22.26 log
Brocade(config)#access-list 1 deny 209.157.29.12 log
Brocade(config)#access-list 1 deny host IPHost1 log
Brocade(config)#access-list 1 permit any
Brocade(config)#int eth 1/1
Brocade(config-if-1/1)#ip access-group 1 in
Brocade(config)#write memory
```

The commands in this example configure an ACL to deny packets from three source IP addresses from being received on port 1/1. The last ACL entry in this ACL permits all packets that are not explicitly denied by the first three ACL entries.

Standard named ACL configuration

This section describes how to configure standard named ACLs with alphanumeric IDs. This section also provides configuration examples.

Standard ACLs permit or deny packets based on source IP address. You can configure up to 99 standard named ACLs. There is no limit to the number of ACL entries an ACL can contain except for the system-wide limitation. For the number of ACL entries supported on a device, refer to [“ACL IDs and entries”](#) on page 1706.

The commands for configuring named ACL entries are different from the commands for configuring numbered ACL entries. The command to configure a numbered ACL is **access-list**. The command for configuring a named ACL is **ip access-list**. In addition, when you configure a numbered ACL entry, you specify all the command parameters on the same command. When you configure a named ACL, you specify the ACL type (standard or extended) and the ACL name with one command, which places you in the configuration level for that ACL. Once you enter the configuration level for the ACL, the command syntax is the same as the syntax for numbered ACLs.

Standard named ACL syntax

Syntax: [no] ip access-list standard <ACL-name> | <ACL-num>

Syntax: deny | permit <source-ip> | <hostname> <wildcard> [log]

or

Syntax: deny | permit <source-ip>/<mask-bits> | <hostname> [log]

Syntax: deny | permit host <source-ip> | <hostname> [log]

Syntax: deny | permit any [log]

Syntax: [no] ip access-group <ACL-name> in | out

The <ACL-name> parameter is the access list name. You can specify a string of up to 256 alphanumeric characters. You can use blanks in the ACL name if you enclose the name in quotation marks (for example, “ACL for Net1”).

The `<ACL-num>` parameter allows you to specify an ACL number if you prefer. If you specify a number, you can specify from 1 – 99 for standard ACLs.

NOTE

For convenience, the software allows you to configure numbered ACLs using the syntax for named ACLs. The software also still supports the older syntax for numbered ACLs. Although the software allows both methods for configuring numbered ACLs, numbered ACLs are always formatted in the startup-config and running-config files in using the older syntax, as follows.

```
access-list 1 deny host 209.157.22.26 log
access-list 1 deny 209.157.22.0 0.0.0.255 log
access-list 1 permit any
access-list 101 deny tcp any any eq http log
```

The **deny** | **permit** parameter indicates whether packets that match a policy in the access list are denied (dropped) or permitted (forwarded).

The `<source-ip>` parameter specifies the source IP address. Alternatively, you can specify the host name.

NOTE

To specify the host name instead of the IP address, the host name must be configured using the DNS resolver on the Brocade device. To configure the DNS resolver name, use the **ip dns server-address...** command at the global CONFIG level of the CLI.

The `<wildcard>` parameter specifies the mask value to compare against the host address specified by the `<source-ip>` parameter. The `<wildcard>` is in dotted-decimal notation (IP address format). It is a four-part value, where each part is 8 bits (one byte) separated by dots, and each bit is a one or a zero. Each part is a number ranging from 0 to 255, for example 0.0.0.255. Zeros in the mask mean the packet source address must match the `<source-ip>`. Ones mean any value matches. For example, the `<source-ip>` and `<wildcard>` values 209.157.22.26 0.0.0.255 mean that all hosts in the Class C subnet 209.157.22.x match the policy.

If you prefer to specify the wildcard (mask value) in CIDR format, you can enter a forward slash after the IP address, then enter the number of significant bits in the mask. For example, you can enter the CIDR equivalent of “209.157.22.26 0.0.0.255” as “209.157.22.26/24”. The CLI automatically converts the CIDR number into the appropriate ACL mask (where zeros instead of ones are the significant bits) and changes the non-significant portion of the IP address into ones. For example, if you specify 209.157.22.26/24 or 209.157.22.26 0.0.0.255, then save the changes to the startup-config file, the value appears as 209.157.22.0/24 (if you have enabled display of subnet lengths) or 209.157.22.0 0.0.0.255 in the startup-config file.

If you enable the software to display IP subnet masks in CIDR format, the mask is saved in the file in “/`<mask-bits>`” format. To enable the software to display the CIDR masks, enter the **ip show-subnet-length** command at the global CONFIG level of the CLI. You can use the CIDR format to configure the ACL entry regardless of whether the software is configured to display the masks in CIDR format.

NOTE

If you use the CIDR format, the ACL entries appear in this format in the running-config and startup-config files, but are shown with subnet mask in the display produced by the **show ip access-list** command.

The **host** <source-ip> | <hostname> parameter lets you specify a host IP address or name. When you use this parameter, you do not need to specify the mask. A mask of all zeros (0.0.0.0) is implied.

The **any** parameter configures the policy to match on all host addresses.

The **log** argument configures the device to generate Syslog entries and SNMP traps for inbound packets that are denied by the access policy.

NOTE

You can enable logging on inbound ACLs and filters that support logging even when the ACLs and filters are already in use. To do so, re-enter the ACL or filter command and add the **log** parameter to the end of the ACL or filter. The software replaces the ACL or filter command with the new one. The new ACL or filter, with logging enabled, takes effect immediately.

The **in** | **out** parameter applies the ACL to incoming or outgoing traffic on the interface to which you apply the ACL. You can apply the ACL to an Ethernet port or virtual interface.

NOTE

If the ACL is bound to a virtual routing interface, you also can specify a subset of ports within the VLAN containing that interface when assigning an ACL to the interface. See [“Enabling ACL filtering based on VLAN membership or VE port membership”](#) on page 1734 for further details.

Configuration example for standard named ACLs

To configure a standard named ACL, enter commands such as the following.

```
Brocade(config)#ip access-list standard Net1
Brocade(config-std-nACL)#deny host 209.157.22.26 log
Brocade(config-std-nACL)#deny 209.157.29.12 log
Brocade(config-std-nACL)#deny host IPHost1 log
Brocade(config-std-nACL)#permit any
Brocade(config-std-nACL)#exit
Brocade(config)#int eth 1/1
Brocade(config-if-e1000-1/1)#ip access-group Net1 in
```

The commands in this example configure a standard ACL named “Net1”. The entries in this ACL deny packets from three source IP addresses from being forwarded on port 1. Since the implicit action for an ACL is “deny”, the last ACL entry in this ACL permits all packets that are not explicitly denied by the first three ACL entries. For an example of how to configure the same entries in a numbered ACL, refer to [“Configuring standard numbered ACLs”](#) on page 1709.

Notice that the command prompt changes after you enter the ACL type and name. The “std” in the command prompt indicates that you are configuring entries for a standard ACL. For an extended ACL, this part of the command prompt is “ext”. The “nACL” indicates that you are configuring a named ACL.

Extended numbered ACL configuration

This section describes how to configure extended numbered ACLs.

Extended ACLs let you permit or deny packets based on the following information:

- IP protocol
- Source IP address or host name
- Destination IP address or host name
- Source TCP or UDP port (if the IP protocol is TCP or UDP)
- Destination TCP or UDP port (if the IP protocol is TCP or UDP)

The IP protocol can be one of the following well-known names or any IP protocol number from 0 – 255:

- Internet Control Message Protocol (ICMP)
- Internet Group Management Protocol (IGMP)
- Internet Gateway Routing Protocol (IGRP)
- Internet Protocol (IP)
- Open Shortest Path First (OSPF)
- Transmission Control Protocol (TCP)
- User Datagram Protocol (UDP)

For TCP and UDP, you also can specify a comparison operator and port name or number. For example, you can configure a policy to block web access to a specific website by denying all TCP port 80 (HTTP) packets from a specified source IP address to the website IP address.

Extended numbered ACL syntax

Syntax: `[no] access-list <ACL-num> deny | permit <ip-protocol> <source-ip> | <hostname> <wildcard> [<operator> <source-tcp/udp-port>] <destination-ip> | <hostname> [<icmp-num> | <icmp-type>] <wildcard> [<tcp/udp comparison operator> <destination-tcp/udp-port>] [802.1p-priority-matching <0 - 7>] [dscp-cos-mapping] [dscp-marking <0-63>] [802.1p-priority-marking <0 - 7>... | dscp-cos-mapping] [dscp-matching <0-63>] [log] [precedence <name> | <0 - 7>] [tos <0 - 63> | <name>] [traffic policy <name>]`

Syntax: `[no] access-list <ACL-num> deny | permit host <ip-protocol> any any`

Syntax: `[no] ip access-group <ACL-num> in | out`

The `<ACL-num>` parameter is the extended access list number. Specify a number from 100 – 199.

The **deny** | **permit** parameter indicates whether packets that match the policy are dropped or forwarded.

The *ip-protocol* parameter indicates the type of IP packet you are filtering. You can specify a well-known name for any protocol whose number is less than 255. For other protocols, you must enter the number. Enter “?” instead of a protocol to list the well-known names recognized by the CLI.

The *source-ip* | *hostname* parameter specifies the source IP host for the policy. If you want the policy to match on all source addresses, enter **any**.

The *wildcard* parameter specifies the portion of the source IP host address to match against. The *wildcard* is in dotted-decimal notation (IP address format). It is a four-part value, where each part is 8 bits (one byte) separated by dots, and each bit is a one or a zero. Each part is a number ranging from 0 to 255, for example 0.0.0.255. Zeros in the mask mean the packet's source address must match the *source-ip*. Ones mean any value matches. For example, the *source-ip* and *wildcard* values 209.157.22.26 0.0.0.255 mean that all hosts in the Class C subnet 209.157.22.x match the policy.

If you prefer to specify the wildcard (mask value) in Classless Interdomain Routing (CIDR) format, you can enter a forward slash after the IP address, then enter the number of significant bits in the mask. For example, you can enter the CIDR equivalent of "209.157.22.26 0.0.0.255" as "209.157.22.26/24". The CLI automatically converts the CIDR number into the appropriate ACL mask (where zeros instead of ones are the significant bits) and changes the non-significant portion of the IP address into zeros. For example, if you specify 209.157.22.26/24 or 209.157.22.26 0.0.0.255, then save the changes to the startup-config file, the value appears as 209.157.22.0/24 (if you have enabled display of subnet lengths) or 209.157.22.0 0.0.0.255 in the startup-config file.

If you enable the software to display IP subnet masks in CIDR format, the mask is saved in the file in *"/ mask-bits "* format. To enable the software to display the CIDR masks, enter the **ip show-subnet-length** command at the global CONFIG level of the CLI. You can use the CIDR format to configure the ACL entry regardless of whether the software is configured to display the masks in CIDR format.

NOTE

If you use the CIDR format, the ACL entries appear in this format in the running-config and startup-config files, but are shown with subnet mask in the display produced by the **show ip access-list** command.

The *destination-ip | hostname* parameter specifies the destination IP host for the policy. If you want the policy to match on all destination addresses, enter **any**.

The *icmp-type | icmp-num* parameter specifies the ICMP protocol type:

- This parameter applies only if you specified **icmp** as the *ip-protocol* value.
- If you use this parameter, the ACL entry is sent to the CPU for processing.
- If you do not specify a message type, the ACL applies to all types of ICMP messages.

The *icmp-num* parameter can be a value from 0 – 255.

The *icmp-type* parameter can have one of the following values, depending on the software version the device is running:

- any-icmp-type
- echo
- echo-reply
- information-request
- log
- mask-reply
- mask-request
- parameter-problem
- redirect
- source-quench

- time-exceeded
- timestamp-reply
- timestamp-request
- traffic policy
- unreachable
- *num*

NOTE

The QoS options listed below are only available if a specific ICMP type is specified for the *icmp-type* parameter and cannot be used with the **any-icmp-type** option above. See [“QoS options for IP ACLs”](#) on page 1740 for more information on using ACLs to perform QoS.

The *tcp/udp comparison operator* parameter specifies a comparison operator for the TCP or UDP port number. This parameter applies only when you specify **tcp** or **udp** as the IP protocol. For example, if you are configuring an entry for HTTP, specify **tcp eq http**. You can enter one of the following operators:

- **eq** – The policy applies to the TCP or UDP port name or number you enter after **eq**.
- **established** – This operator applies only to TCP packets. If you use this operator, the policy applies to TCP packets that have the ACK (Acknowledgment) or RST (Reset) bits set on (set to “1”) in the Control Bits field of the TCP packet header. Thus, the policy applies only to established TCP sessions, not to new sessions. Refer to Section 3.1, “Header Format”, in RFC 793 for information about this field.

NOTE

This operator applies only to destination TCP ports, not source TCP ports.

- **gt** – The policy applies to TCP or UDP port numbers greater than the port number or the numeric equivalent of the port name you enter after **gt**.
- **lt** – The policy applies to TCP or UDP port numbers that are less than the port number or the numeric equivalent of the port name you enter after **lt**.
- **neq** – The policy applies to all TCP or UDP port numbers except the port number or port name you enter after **neq**.
- **range** – The policy applies to all TCP or UDP port numbers that are between the first TCP or UDP port name or number and the second one you enter following the **range** parameter. The range includes the port names or numbers you enter. For example, to apply the policy to all ports between and including 23 (Telnet) and 53 (DNS), enter the following: **range 23 53**. The first port number in the range must be lower than the last number in the range.

The *tcp/udp-port* parameter specifies the TCP or UDP port number or well-known name. You can specify a well-known name for any application port whose number is less than 1024. For other application ports, you must enter the number. Enter “?” instead of a port to list the well-known names recognized by the CLI.

The **in | out** parameter specifies that the ACL applies to incoming traffic on the interface to which you apply the ACL. You can apply the ACL to an Ethernet port or a virtual interface.

NOTE

If the ACL is for a virtual routing interface, you also can specify a subset of ports within the VLAN containing that interface when assigning an ACL to the interface. Refer to [“Configuring standard numbered ACLs”](#) on page 1709.

The **precedence** *name* | *num* parameter of the **ip access-list** command specifies the IP precedence. The precedence option for of an IP packet is set in a three-bit field following the four-bit header-length field of the packet's header. You can specify one of the following:

- **critical** or **5** – The ACL matches packets that have the critical precedence. If you specify the option number instead of the name, specify number 5.
- **flash** or **3** – The ACL matches packets that have the flash precedence. If you specify the option number instead of the name, specify number 3.
- **flash-override** or **4** – The ACL matches packets that have the flash override precedence. If you specify the option number instead of the name, specify number 4.
- **immediate** or **2** – The ACL matches packets that have the immediate precedence. If you specify the option number instead of the name, specify number 2.
- **internet** or **6** – The ACL matches packets that have the internetwork control precedence. If you specify the option number instead of the name, specify number 6.
- **network** or **7** – The ACL matches packets that have the network control precedence. If you specify the option number instead of the name, specify number 7.
- **priority** or **1** – The ACL matches packets that have the priority precedence. If you specify the option number instead of the name, specify number 1.
- **routine** or **0** – The ACL matches packets that have the routine precedence. If you specify the option number instead of the name, specify number 0.

The **tos** *name* | *num* parameter of the **ip access-list** command specifies the IP ToS. You can specify one of the following:

- **max-reliability** or **2** – The ACL matches packets that have the maximum reliability ToS. The decimal value for this option is 2.
- **max-throughput** or **4** – The ACL matches packets that have the maximum throughput ToS. The decimal value for this option is 4.
- **min-delay** or **8** – The ACL matches packets that have the minimum delay ToS. The decimal value for this option is 8.
- **min-monetary-cost** or **1** – The ACL matches packets that have the minimum monetary cost ToS. The decimal value for this option is 1.

NOTE

This value is not supported on 10 Gigabit Ethernet modules.

- **normal** or **0** – The ACL matches packets that have the normal ToS. The decimal value for this option is 0.
- *num* – A number from 0 – 15 that is the sum of the numeric values of the options you want. The ToS field is a four-bit field following the Precedence field in the IP header. You can specify one or more of the following. To select more than one option, enter the decimal value that is equivalent to the sum of the numeric values of all the ToS options you want to select. For example, to select the **max-reliability** and **min-delay** options, enter number 10. To select all options, select 15.

NOTE

The following QoS options are only available if a specific ICMP type is specified and cannot be used with the **any-icmp-type** option set for the *icmp-type* parameter. See [“QoS options for IP ACLs”](#) on page 1740 for more information on using ACLs to perform QoS.

The **802.1p-priority-matching** option inspects the 802.1p bit in the ACL that can be used with adaptive rate limiting. Enter a value from 0 – 7. For details, refer to [“Inspecting the 802.1p bit in the ACL for adaptive rate limiting”](#) on page 1781.

The **dscp-cos-mapping** option maps the DSCP value in incoming packets to a hardware table that provides mapping of each of the 0 – 63 DSCP values, and distributes them among eight traffic classes (internal priorities) and eight 802.1p priorities.

NOTE

The **dscp-cos-mapping** option overrides port-based priority settings.

NOTE

The **dscp-cos-mapping** option is **not** supported for FCX devices. The **dscp-cos-mapping** option is supported on FESX and FSX devices only.

The **dscp-marking** option enables you to configure an ACL that marks matching packets with a specified DSCP value. Enter a value from 0 – 63. Refer to [“Using an IP ACL to mark DSCP values \(DSCP marking\)”](#) on page 1742.

The **dscp-matching** option matches on the packet’s DSCP value. Enter a value from 0 – 63. This option does not change the packet’s forwarding priority through the device or mark the packet. Refer to [“DSCP matching”](#) on page 1744.

The **log** parameter enables SNMP traps and Syslog messages for inbound packets denied by the ACL:

- You can enable logging on inbound ACLs and filters that support logging even when the ACLs and filters are already in use. To do so, re-enter the **ACL** or **filter** command and add the **log** parameter to the end of the ACL or filter. The software replaces the **ACL** or **filter** command with the new one. The new ACL or filter, with logging enabled, takes effect immediately.

The **traffic-policy** option enables the device to rate limit inbound traffic and to count the packets and bytes per packet to which ACL permit or deny clauses are applied. For configuration procedures and examples, refer to the chapter [“Traffic Policies”](#) on page 1773.

Configuration examples for extended numbered ACLs

To configure an extended access control list that blocks all Telnet traffic received on port 1/1 from IP host 209.157.22.26, enter the following commands.

```
Brocade(config)#access-list 101 deny tcp host 209.157.22.26 any eq telnet log
Brocade(config)#access-list 101 permit ip any any
Brocade(config)#int eth 1/1
Brocade(config-if-e1000-1/1)#ip access-group 101 in
Brocade(config)#write memory
```

Here is another example of commands for configuring an extended ACL and applying it to an interface. These examples show many of the syntax choices. Notice that some of the entries are configured to generate log entries while other entries are not thus configured.

```

Brocade(config)#access-list 102 perm icmp 209.157.22.0/24 209.157.21.0/24
Brocade(config)#access-list 102 deny igmp host rkwong 209.157.21.0/24 log
Brocade(config)#access-list 102 deny igmp 209.157.21.0/24 host rkwong log
Brocade(config)#access-list 102 deny ip host 209.157.21.100 host 209.157.22.1 log
Brocade(config)#access-list 102 deny ospf any any log
Brocade(config)#access-list 102 permit ip any any

```

The first entry permits ICMP traffic from hosts in the 209.157.22.x network to hosts in the 209.157.21.x network.

The second entry denies IGMP traffic from the host device named “rkwong” to the 209.157.21.x network.

The third entry denies IGMP traffic from the 209.157.21.x network to the host device named “rkwong”.

The fourth entry denies all IP traffic from host 209.157.21.100 to host 209.157.22.1 and generates Syslog entries for packets that are denied by this entry.

The fifth entry denies all OSPF traffic and generates Syslog entries for denied traffic.

The sixth entry permits all packets that are not explicitly denied by the other entries. Without this entry, the ACL would deny all incoming or outgoing IP traffic on the ports to which you assign the ACL.

The following commands apply ACL 102 to the incoming traffic on port 1/2 and to the incoming traffic on port 4/3.

```

Brocade(config)#int eth 1/2
Brocade(config-if-1/2)#ip access-group 102 in
Brocade(config-if-1/2)#exit
Brocade(config)#int eth 4/3
Brocade(config-if-4/3)#ip access-group 102 in
Brocade(config)#write memory

```

Here is another example of an extended ACL.

```

Brocade(config)#access-list 103 deny tcp 209.157.21.0/24 209.157.22.0/24
Brocade(config)#access-list 103 deny tcp 209.157.21.0/24 eq ftp 209.157.22.0/24
Brocade(config)#access-list 103 deny tcp 209.157.21.0/24 209.157.22.0/24 lt
telnet neq 5
Brocade(config)#access-list 103 deny udp any range 5 6 209.157.22.0/24 range 7 8
Brocade(config)#access-list 103 permit ip any any

```

The first entry in this ACL denies TCP traffic from the 209.157.21.x network to the 209.157.22.x network.

The second entry denies all FTP traffic from the 209.157.21.x network to the 209.157.22.x network.

The third entry denies TCP traffic from the 209.157.21.x network to the 209.157.22.x network, if the TCP port number of the traffic is less than the well-known TCP port number for Telnet (23), and if the TCP port is not equal to 5. Thus, TCP packets whose TCP port numbers are 5 or are greater than 23 are allowed.

The fourth entry denies UDP packets from any source to the 209.157.22.x network, if the UDP port number from the source network is 5 or 6 and the destination UDP port is 7 or 8.

The fifth entry permits all packets that are not explicitly denied by the other entries. Without this entry, the ACL would deny all incoming or outgoing IP traffic on the ports to which you assign the ACL.

The following commands apply ACL 103 to the incoming traffic on ports 2/1 and 2/2.

```
Brocade(config)#int eth 2/1
Brocade(config-if-2/1)#ip access-group 103 in
Brocade(config-if-2/1)#exit
Brocade(config)#int eth 0/2/2
Brocade(config-if-2/2)#ip access-group 103 in
Brocade(config)#write memory
```

Extended named ACL configuration

The commands for configuring named ACL entries are different from the commands for configuring numbered ACL entries. The command to configure a numbered ACL is **access-list**. The command for configuring a named ACL is **ip access-list**. In addition, when you configure a numbered ACL entry, you specify all the command parameters on the same command. When you configure a named ACL, you specify the ACL type (standard or extended) and the ACL number with one command, which places you in the configuration level for that ACL. Once you enter the configuration level for the ACL, the command syntax is the same as the syntax for numbered ACLs.

Extended ACLs let you permit or deny packets based on the following information:

- IP protocol
- Source IP address or host name
- Destination IP address or host name
- Source TCP or UDP port (if the IP protocol is TCP or UDP)
- Destination TCP or UDP port (if the IP protocol is TCP or UDP)

The IP protocol can be one of the following well-known names or any IP protocol number from 0 – 255:

- Internet Control Message Protocol (ICMP)
- Internet Group Management Protocol (IGMP)
- Internet Gateway Routing Protocol (IGRP)
- Internet Protocol (IP)
- Open Shortest Path First (OSPF)
- Transmission Control Protocol (TCP)
- User Datagram Protocol (UDP)

For TCP and UDP, you also can specify a comparison operator and port name or number. For example, you can configure a policy to block web access to a specific website by denying all TCP port 80 (HTTP) packets from a specified source IP address to the website's IP address.

Extended named ACL syntax

Syntax: `[no] ip access-list extended <ACL-name> deny | permit <ip-protocol> <source-ip> | <hostname> <wildcard> [<operator> <source-tcp/udp-port>] <destination-ip> | <hostname> [<icmp-num> | <icmp-type>] <wildcard> [<tcp/udp comparison operator> <destination-tcp/udp-port>] [802.1p-priority-matching <0 - 7>] [dscp-cos-mapping] [dscp-marking <0-63> [802.1p-priority-marking <0 - 7>... | dscp-cos-mapping]] [dscp-matching <0-63>] [log] [precedence <name> | <0 - 7>] [tos <0 - 63> | <name>] [traffic policy <name>]`

Syntax: `[no] ip access-group <num> in | out`

The *<ACL-name>* parameter is the access list name. You can specify a string of up to 256 alphanumeric characters. You can use blanks in the ACL name if you enclose the name in quotation marks (for example, "ACL for Net1").

The **deny** | **permit** parameter indicates whether packets that match the policy are dropped or forwarded.

The *ip-protocol* parameter indicates the type of IP packet you are filtering. You can specify a well-known name for any protocol whose number is less than 255. For other protocols, you must enter the number. Enter "?" instead of a protocol to list the well-known names recognized by the CLI.

The *source-ip* | *hostname* parameter specifies the source IP host for the policy. If you want the policy to match on all source addresses, enter **any**.

The *wildcard* parameter specifies the portion of the source IP host address to match against. The *wildcard* is in dotted-decimal notation (IP address format). It is a four-part value, where each part is 8 bits (one byte) separated by dots, and each bit is a one or a zero. Each part is a number ranging from 0 to 255, for example 0.0.0.255. Zeros in the mask mean the packet's source address must match the *source-ip*. Ones mean any value matches. For example, the *source-ip* and *wildcard* values 209.157.22.26 0.0.0.255 mean that all hosts in the Class C subnet 209.157.22.x match the policy.

If you prefer to specify the wildcard (mask value) in Classless Interdomain Routing (CIDR) format, you can enter a forward slash after the IP address, then enter the number of significant bits in the mask. For example, you can enter the CIDR equivalent of "209.157.22.26 0.0.0.255" as "209.157.22.26/24". The CLI automatically converts the CIDR number into the appropriate ACL mask (where zeros instead of ones are the significant bits) and changes the non-significant portion of the IP address into zeros. For example, if you specify 209.157.22.26/24 or 209.157.22.26 0.0.0.255, then save the changes to the startup-config file, the value appears as 209.157.22.0/24 (if you have enabled display of subnet lengths) or 209.157.22.0 0.0.0.255 in the startup-config file.

If you enable the software to display IP subnet masks in CIDR format, the mask is saved in the file in *" / mask-bits "* format. To enable the software to display the CIDR masks, enter the **ip show-subnet-length** command at the global CONFIG level of the CLI. You can use the CIDR format to configure the ACL entry regardless of whether the software is configured to display the masks in CIDR format.

NOTE

If you use the CIDR format, the ACL entries appear in this format in the running-config and startup-config files, but are shown with subnet mask in the display produced by the **show ip access-list** command.

The *destination-ip | hostname* parameter specifies the destination IP host for the policy. If you want the policy to match on all destination addresses, enter **any**.

The *icmp-type | icmp-num* parameter specifies the ICMP protocol type:

- This parameter applies only if you specified **icmp** as the *ip-protocol* value.
- If you use this parameter, the ACL entry is sent to the CPU for processing.
- If you do not specify a message type, the ACL applies to all types of ICMP messages.

The *icmp-num* parameter can be a value from 0 – 255.

The *icmp-type* parameter can have one of the following values, depending on the software version the device is running:

- any-icmp-type
- echo
- echo-reply
- information-request
- log
- mask-reply
- mask-request
- parameter-problem
- redirect
- source-quench
- time-exceeded
- timestamp-reply
- timestamp-request
- traffic policy
- unreachable
- *num*

NOTE

The QoS options listed below are only available if a specific ICMP type is specified for the *icmp-type* parameter and cannot be used with the **any-icmp-type** option above. See [“QoS options for IP ACLs”](#) on page 1740 for more information on using ACLs to perform QoS.

The *tcp/udp comparison operator* parameter specifies a comparison operator for the TCP or UDP port number. This parameter applies only when you specify **tcp** or **udp** as the IP protocol. For example, if you are configuring an entry for HTTP, specify **tcp eq http**. You can enter one of the following operators:

- **eq** – The policy applies to the TCP or UDP port name or number you enter after **eq**.
- **established** – This operator applies only to TCP packets. If you use this operator, the policy applies to TCP packets that have the ACK (Acknowledgment) or RST (Reset) bits set on (set to “1”) in the Control Bits field of the TCP packet header. Thus, the policy applies only to established TCP sessions, not to new sessions. Refer to Section 3.1, “Header Format”, in RFC 793 for information about this field.

NOTE

This operator applies only to destination TCP ports, not source TCP ports.

- **gt** – The policy applies to TCP or UDP port numbers greater than the port number or the numeric equivalent of the port name you enter after **gt**.
- **lt** – The policy applies to TCP or UDP port numbers that are less than the port number or the numeric equivalent of the port name you enter after **lt**.
- **neq** – The policy applies to all TCP or UDP port numbers except the port number or port name you enter after **neq**.
- **range** – The policy applies to all TCP or UDP port numbers that are between the first TCP or UDP port name or number and the second one you enter following the **range** parameter. The range includes the port names or numbers you enter. For example, to apply the policy to all ports between and including 23 (Telnet) and 53 (DNS), enter the following: **range 23 53**. The first port number in the range must be lower than the last number in the range.

The *tcp/udp-port* parameter specifies the TCP or UDP port number or well-known name. You can specify a well-known name for any application port whose number is less than 1024. For other application ports, you must enter the number. Enter “?” instead of a port to list the well-known names recognized by the CLI.

The **in | out** parameter specifies that the ACL applies to incoming traffic on the interface to which you apply the ACL. You can apply the ACL to an Ethernet port or a virtual interface.

NOTE

If the ACL is for a virtual routing interface, you also can specify a subset of ports within the VLAN containing that interface when assigning an ACL to the interface. Refer to [“Configuring standard numbered ACLs”](#) on page 1709.

The **precedence name | num** parameter of the **ip access-list** command specifies the IP precedence. The precedence option for of an IP packet is set in a three-bit field following the four-bit header-length field of the packet’s header. You can specify one of the following:

- **critical** or **5** – The ACL matches packets that have the critical precedence. If you specify the option number instead of the name, specify number 5.
- **flash** or **3** – The ACL matches packets that have the flash precedence. If you specify the option number instead of the name, specify number 3.
- **flash-override** or **4** – The ACL matches packets that have the flash override precedence. If you specify the option number instead of the name, specify number 4.
- **immediate** or **2** – The ACL matches packets that have the immediate precedence. If you specify the option number instead of the name, specify number 2.
- **internet** or **6** – The ACL matches packets that have the internetwork control precedence. If you specify the option number instead of the name, specify number 6.
- **network** or **7** – The ACL matches packets that have the network control precedence. If you specify the option number instead of the name, specify number 7.
- **priority** or **1** – The ACL matches packets that have the priority precedence. If you specify the option number instead of the name, specify number 1.
- **routine** or **0** – The ACL matches packets that have the routine precedence. If you specify the option number instead of the name, specify number 0.

The **tos name | num** parameter of the **ip access-list** command specifies the IP ToS. You can specify one of the following:

- **max-reliability** or **2** – The ACL matches packets that have the maximum reliability ToS. The decimal value for this option is 2.
- **max-throughput** or **4** – The ACL matches packets that have the maximum throughput ToS. The decimal value for this option is 4.
- **min-delay** or **8** – The ACL matches packets that have the minimum delay ToS. The decimal value for this option is 8.
- **min-monetary-cost** or **1** – The ACL matches packets that have the minimum monetary cost ToS. The decimal value for this option is 1.

NOTE

This value is not supported on 10 Gigabit Ethernet modules.

- **normal** or **0** – The ACL matches packets that have the normal ToS. The decimal value for this option is 0.
- *num* – A number from 0 – 15 that is the sum of the numeric values of the options you want. The ToS field is a four-bit field following the Precedence field in the IP header. You can specify one or more of the following. To select more than one option, enter the decimal value that is equivalent to the sum of the numeric values of all the ToS options you want to select. For example, to select the **max-reliability** and **min-delay** options, enter number 10. To select all options, select 15.

NOTE

The following QoS options are only available if a specific ICMP type is specified and cannot be used with the **any-icmp-type** option set for the *icmp-type* parameter. See [“QoS options for IP ACLs”](#) on page 1740 for more information on using ACLs to perform QoS.

The **802.1p-priority-matching** option inspects the 802.1p bit in the ACL that can be used with adaptive rate limiting. Enter a value from 0 – 7. For details, refer to [“Inspecting the 802.1p bit in the ACL for adaptive rate limiting”](#) on page 1781.

The **dscp-cos-mapping** option maps the DSCP value in incoming packets to a hardware table that provides mapping of each of the 0 – 63 DSCP values, and distributes them among eight traffic classes (internal priorities) and eight 802.1p priorities.

NOTE

The **dscp-cos-mapping** option overrides port-based priority settings.

NOTE

The **dscp-cos-mapping** option is **not** supported for FCX devices. The **dscp-cos-mapping** option is supported on FESX and FSX devices only.

The **dscp-marking** option enables you to configure an ACL that marks matching packets with a specified DSCP value. Enter a value from 0 – 63. Refer to [“Using an IP ACL to mark DSCP values \(DSCP marking\)”](#) on page 1742.

The **dscp-matching** option matches on the packet’s DSCP value. Enter a value from 0 – 63. This option does not change the packet’s forwarding priority through the device or mark the packet. Refer to [“DSCP matching”](#) on page 1744.

The **log** parameter enables SNMP traps and Syslog messages for inbound packets denied by the ACL:

- You can enable logging on inbound ACLs and filters that support logging even when the ACLs and filters are already in use. To do so, re-enter the **ACL** or **filter** command and add the **log** parameter to the end of the ACL or filter. The software replaces the **ACL** or **filter** command with the new one. The new ACL or filter, with logging enabled, takes effect immediately.

The **traffic-policy** option enables the device to rate limit inbound traffic and to count the packets and bytes per packet to which ACL permit or deny clauses are applied. For configuration procedures and examples, refer to the chapter [“Traffic Policies”](#) on page 1773.

Configuration example for extended named ACLs

To configure an extended named ACL, enter the **ip access-list extended <ACL_name>** command.

```
Brocade(config)#ip access-list extended "block Telnet"
Brocade(config-ext-nACL)#deny tcp host 209.157.22.26 any eq telnet log
Brocade(config-ext-nACL)#permit ip any any
Brocade(config-ext-nACL)#exit
Brocade(config)#int eth 1/1
Brocade(config-if-1/1)#ip access-group "block Telnet" in
```

The options at the ACL configuration level and the syntax for the **ip access-group** command are the same for numbered and named ACLs and are described in [“Extended numbered ACL configuration”](#) on page 1714 and [“Extended numbered ACL configuration”](#) on page 1714.

Applying egress ACLs to Control (CPU) traffic

By default, outbound ACLs are not applied to traffic generated by the CPU. This must be enabled using the **enable egress-acl-on-control-traffic** command.

Syntax: **enable egress-acl-on-control-traffic**

Preserving user input for ACL TCP/UDP port numbers

ACL implementations automatically display the TCP/UDP port name instead of the port number, regardless of user preference, unless the device is configured to preserve user input. When the option to preserve user input is enabled, the system will display either the port name or the number.

To enable this feature, enter the **ip preserve-ACL-user-input-format** command.

```
Brocade(config)#ip preserve-ACL-user-input-format
```

Syntax: **ip preserve-ACL-user-input-format**

The following example shows how this feature works for a TCP port (this feature works the same way for UDP ports). In this example, the user identifies the TCP port by number (80) when configuring ACL group 140. However, **show ip access-list 140** reverts back to the port name for the TCP port (http in this example). After the user issues the new **ip preserve-ACL-user-input-format** command, **show ip access-list 140** displays either the TCP port number or name, depending on how it was configured by the user.

```

Brocade(config)#access-list 140 permit tcp any any eq 80
Brocade(config)#access-list 140 permit tcp any any eq ftp
Brocade#show ip access-lists 140
Extended IP access list 140
permit tcp any any eq http
permit tcp any any eq ftp
Brocade(config)#ip preserve-ACL-user-input-format
Brocade#show ip access-lists 140
Extended IP access list 140
permit tcp any any eq 80
permit tcp any any eq ftp

```

ACL comment text management

ACL comment text describes entries in an ACL. The comment text appears in the output of **show** commands that display ACL information.

This section describes how to add, delete, and view ACL comments.

Adding a comment to an entry in a numbered ACL

To add comments to entries in a numbered ACL, enter commands such as the following.

```

Brocade(config)#access-list 100 remark The following line permits TCP packets
Brocade(config)#access-list 100 permit tcp 192.168.4.40/24 2.2.2.2/24
Brocade(config)#access-list 100 remark The following permits UDP packets
Brocade(config)#access-list 100 permit udp 192.168.2.52/24 2.2.2.2/24
Brocade(config)#access-list 100 deny ip any any

```

You can add comments to entries in a numbered ACL using the syntax for named ACLs. For example, using the same example configuration above, you could instead enter the following commands.

```

Brocade(config)#ip access-list extended 100
Brocade(config-ext-nACL)#remark The following line permits TCP packets
Brocade(config-ext-nACL)#permit tcp 192.168.4.40/24 2.2.2.2/24
Brocade(config-ext-nACL)#remark The following permits UDP packets
Brocade(config-ext-nACL)#permit udp 192.168.2.52/24 2.2.2.2/24
Brocade(config-ext-nACL)#deny ip any any

```

Syntax: [no] **access-list** <ACL-num> **remark** <comment-text>

or

Syntax: [no] **ip access-list** **standard** | **extended** <ACL-num>

Syntax: **remark** <comment-text>

For <ACL-num>, enter the number of the ACL.

The <comment-text> can be up to 128 characters in length. The comment must be entered separately from the actual ACL entry; that is, you cannot enter the ACL entry and the ACL comment with the same **access-list** or **ip access-list** command. Also, in order for the remark to be displayed correctly in the output of **show** commands, the comment must be entered immediately before the ACL entry it describes. Note that an ACL comment is tied to the ACL entry immediately following the comment. Therefore, if the ACL entry is removed, the ACL comment is also removed.

The **standard** | **extended** parameter indicates the ACL type.

Adding a comment to an entry in a named ACL

To add comments to entries in a named ACL, enter commands such as the following.

```
Brocade(config)#ip access-list extended TCP/UDP
Brocade(config-ext-nACL)#remark The following line permits TCP packets
Brocade(config-ext-nACL)#permit tcp 192.168.4.40/24 2.2.2.2/24
Brocade(config-ext-nACL)#remark The following permits UDP packets
Brocade(config-ext-nACL)#permit udp 192.168.2.52/24 2.2.2.2/24
Brocade(config-ext-nACL)#deny ip any any
```

Syntax: [no] **access-list** **standard** | **extended** <ACL-name>

Syntax: **remark** <comment-text>

The **standard** | **extended** parameter indicates the ACL type.

For <ACL-name>, enter the name of the ACL.

The <comment-text> can be up to 128 characters in length. The comment must be entered separately from the actual ACL entry; that is, you cannot enter the ACL entry and the ACL comment with the same **ip access-list** command. Also, in order for the remark to be displayed correctly in the output of show commands, the comment must be entered immediately before the ACL entry it describes. Note that an ACL comment is tied to the ACL entry immediately following the comment. Therefore, if the ACL entry is removed, the ACL comment is also removed.

Deleting a comment from an ACL entry

To delete a comment from an ACL entry, enter commands such as the following.

```
Brocade(config)#ip access-list standard 99
Brocade(config)#no remark The following line permits TCP packets
```

Syntax: **no remark** <comment-text>

Viewing comments in an ACL

You can use the following commands to display comments for ACL entries:

- **show running-config**
- **show access-list**
- **show ip access-list**

The following shows the comment text for a numbered ACL, ACL 100, in a **show running-config** display.

```
Brocade#show running-config
...
access-list 100 remark The following line permits TCP packets
access-list 100 permit tcp 192.168.4.40/24 2.2.2.2/24
access-list 100 remark The following line permits UDP packets
access-list 100 permit udp 192.168.2.52/24 2.2.2.2/24
access-list 100 deny ip any any
```

Syntax: show running-config

The following example shows the comment text for an ACL in a **show access-list** display. The output is identical in a **show ip access-list** display.

```
Brocade#show access-list
IP access list rate-limit 100 aaaa.bbbb.cccc
Extended IP access list TCP/UDP (Total flows: N/A, Total packets: N/A)
ACL Remark: The following line permits TCP packets
permit tcp 0.0.0.40 255.255.255.0 0.0.0.2 255.255.255.0 (Flows: N/A, Packets:
N/A)
ACL Remark: The following line permits UDP packets
permit udp 0.0.0.52 255.255.255.0 0.0.0.2 255.255.255.0 (Flows: N/A, Packets:
N/A)
deny ip any any (Flows: N/A, Packets: N/A)
```

Syntax: show access-list <ACL-num> | <ACL-name> | all

or

Syntax: show ip access-list <ACL-num> | <ACL-name> | all

Applying an ACL to a virtual interface in a protocol- or subnet-based VLAN

By default, when you apply an ACL to a virtual interface in a protocol-based or subnet-based VLAN, the ACL takes effect on all protocol or subnet VLANs to which the untagged port belongs. To prevent the Brocade device from denying packets on other virtual interfaces that do not have an ACL applied, configure an ACL that permits packets in the IP subnet of the virtual interface in all protocol-based or subnet-based VLANs to which the untagged port belongs. The following is an example configuration.

```
Brocade#conf t
Brocade(config)#vlan 1 name DEFAULT-VLAN by port
Brocade(config-vlan-1)#ip-subnet 192.168.10.0 255.255.255.0
Brocade(config-vlan-ip-subnet)#static ethe 1
Brocade(config-vlan-ip-subnet)#router-interface ve 10
Brocade(config-vlan-ip-subnet)#ip-subnet 10.15.1.0 255.255.255.0
Brocade(config-vlan-ip-subnet)#static ethe 1
Brocade(config-vlan-ip-subnet)#router-interface ve 20
Brocade(config-vlan-ip-subnet)#logging console
Brocade(config-vlan-ip-subnet)#exit
Brocade(config-vlan-1)#no vlan-dynamic-discovery
Vlan dynamic discovery is disabled
Brocade(config-vlan-1)#int e 2
Brocade(config-if-e1000-2)#disable
Brocade(config-if-e1000-2)#interface ve 10
Brocade(config-vif-10)#ip address 192.168.10.254 255.255.255.0
Brocade(config-vif-10)#int ve 20
Brocade(config-vif-20)#ip access-group test1 in
Brocade(config-vif-20)#ip address 10.15.1.10 255.255.255.0
Brocade(config-vif-20)#exit
Brocade(config)#ip access-list extended test1
```

```

Brocade(config-ext-nACL)#permit ip 10.15.1.0 0.0.0.255 any log
Brocade(config-ext-nACL)#permit ip 192.168.10.0 0.0.0.255 any log
Brocade(config-ext-nACL)#end
Brocade#

```

ACL logging

Brocade devices support ACL logging of inbound packets that are sent to the CPU for processing (denied packets).

NOTE

ACL logging is not supported for outbound packets or any packets that are processed in hardware (permitted packets).

You may want the software to log entries in the Syslog for packets that are denied by ACL filters. ACL logging is disabled by default; it must be explicitly enabled on a port.

When you enable logging for ACL entries, statistics for packets that match the deny conditions of the ACL entries are logged. For example, if you configure a standard ACL entry to deny all packets from source address 209.157.22.26, statistics for packets that are explicitly denied by the ACL entry are logged in the Syslog buffer and in SNMP traps sent by the Brocade device.

The first time an ACL entry denies a packet, the software immediately generates a Syslog entry and an SNMP trap. The software also starts a five-minute timer. The timer keeps track of all packets explicitly denied by the ACL entries. After five minutes, the software generates a single Syslog entry for each ACL entry that denied a packet. The Syslog entry (message) indicates the number of packets denied by the ACL entry during the previous five minutes. Note however that packet count may be inaccurate if the packet rate is high and exceeds the CPU processing rate.

If no ACL entries explicitly deny packets during an entire five-minute timer interval, the timer stops. The timer restarts when an ACL entry explicitly denies a packet.

NOTE

The timer for logging packets denied by MAC address filters is a different timer than the ACL logging timer.

Configuration notes for ACL logging

Note the following points before configuring ACL logging:

- ACL logging is supported for denied packets, which are sent to the CPU for logging. ACL logging is not supported for permitted packets.
- ACL logging is not supported for dynamic ACLs with multi-device port authentication and 802.1X.
- Packets that are denied by ACL filters are logged in the Syslog based on a sample time-period.
- You can enable ACL logging on physical and virtual interfaces.
- When ACL logging is disabled, packets that match the ACL rule are forwarded or dropped in hardware.
- ACL logging is supported on FCX and ICX devices for ACLs that are applied to network management access features such as Telnet, SSH, Web, and SNMP.

- When an ACL that includes an entry with a logging option is applied to a port that has logging enabled, and then the same ACL is applied to another port on the same system, traffic on the latter port is also logged, whether logging is explicitly enabled for that latter port or not.

On the other hand, when an ACL is applied to a port that has logging disabled, and then the same ACL is applied to another port on the same system, traffic on the latter port is also not logged, whether logging is explicitly enabled for that latter port or not.

NOTE

The above limitation applies only to IPv4 ACLs, it does not apply to the use of ACLs to log IPv6 traffic.

- When ACL logging is enabled on FastIron WS, Brocade FCX Series and ICX devices, packets sent to the CPU are automatically rate limited to prevent CPU overload.
- When ACL logging is enabled on FastIron X Series devices, Brocade recommends that you configure a traffic conditioner, then link the ACL to the traffic conditioner to prevent CPU overload. For example:

```
Brocade(config)#traffic-policy TPD1 rate-limit fixed 100 exceed-action drop
Brocade(config)#access-list 101 deny ip host 210.10.12.2 any traffic-policy
TPD1 log
```

- ACL logging is intended for debugging purposes. Brocade recommends that you disable ACL logging after the debug session is over.

Configuration tasks for ACL logging

To enable ACL logging, complete the following steps:

1. Create ACL entries with the log option
2. Enable ACL logging on individual ports

NOTE

The command syntax for enabling ACL logging is different on IPv4 devices than on IPv6 devices. See the configuration examples in the next section.

3. Bind the ACLs to the ports on which ACL logging is enabled

Example ACL logging configuration

The following shows an example ACL logging configuration on an IPv4 device.

```
Brocade(config)#access-list 1 deny host 209.157.22.26 log
Brocade(config)#access-list 1 deny 209.157.29.12 log
Brocade(config)#access-list 1 deny host IPHost1 log
Brocade(config)#access-list 1 permit any
Brocade(config)#interface e 1/4
Brocade(config-if-e1000-1/4)#ACL-logging
Brocade(config-if-e1000-1/4)#ip access-group 1 in
```

The above commands create ACL entries that include the log option, enable ACL logging on interface e 1/4, then bind the ACL to interface e 1/4. Statistics for packets that match the deny statements will be logged.

NOTE

The **ACL-logging** command shown above is **not** required for FWS devices.

Syntax: ACL-logging

The **ACL-logging** command applies to IPv4 devices only. For IPv6 devices, use the **logging-enable** command as shown in the following example.

The following shows an example configuration on an IPv6 device.

```
Brocade(config)#ipv6 acc ACL_log_v6
Brocade(config-ipv6-access-list ACL_log_v6)#logging-enable
Brocade(config-ipv6-access-list ACL_log_v6)# deny ipv6 host 2001::1 any log
Brocade(config-ipv6-access-list ACL_log_v6)#inter e 9/12
Brocade(config-if-e1000-9/12)#ipv6 traffic-filter ACL_log_v6 in
```

The above commands create ACL entries that include the log option, then bind the ACL to interface e 9/12. Statistics for packets that match the deny statement will be logged.

Syntax: logging-enable

NOTE

The **logging-enabled** command applies to IPv6 devices only. For IPv4 devices, use the **ACL-logging** command as shown in the previous example.

Displaying ACL Log Entries

The first time an entry in an ACL permits or denies a packet and logging is enabled for that entry, the software generates a Syslog message and an SNMP trap. Messages for packets permitted or denied by ACLs are at the warning level of the Syslog.

When the first Syslog entry for a packet permitted or denied by an ACL is generated, the software starts an ACL timer. After this, the software sends Syslog messages every five minutes. If an ACL entry does not permit or deny any packets during the timer interval, the software does not generate a Syslog entry for that ACL entry.

NOTE

For an ACL entry to be eligible to generate a Syslog entry for denied packets, logging must be enabled for the entry. The Syslog contains entries only for the ACL entries that deny packets and have logging enabled.

To display Syslog entries, enter the **show log** command from any CLI prompt:

Enabling strict control of ACL filtering of fragmented packets

```
Brocade#show log
Syslog logging: enabled (0 messages dropped, 2 flushes, 0 overruns)
  Buffer logging: level ACDMEINW, 9 messages logged
  level code: A=alert C=critical D=debugging M=emergency E=error
              I=informational N=notification W=warning

Dynamic Log Buffer (50 lines):
0d00h12m18s:W:ACL: ACL: List 122 denied tcp 20.20.15.6(0)(Ethernet 4 0000.0804.01
20.20.18.6(0), 1 event(s)
0d00h12m18s:W:ACL: ACL: List 122 denied tcp 20.20.15.2(0)(Ethernet 4 0000.0804.01

0d00h12m18s:W:ACL: ACL: List 122 denied tcp 20.20.15.4(0)(Ethernet 4 0000.0804.01
20.20.18.4(0), 1 event(s)
0d00h12m18s:W:ACL: ACL: List 122 denied tcp 20.20.15.3(0)(Ethernet 4 0000.0804.01
20.20.18.3(0), 1 event(s)
0d00h12m18s:W:ACL: ACL: List 122 denied tcp 20.20.15.5(0)(Ethernet 4 0000.0804.01
20.20.18.5(0), 1 event(s)
0d00h12m18s:I:ACL: 122 applied to port 4 by  from console session
0d00h10m12s:I:ACL: 122 removed from port 4 by  from console session
0d00h09m56s:I:ACL: 122 removed from port 4 by  from console session
0d00h09m38s:I:ACL: 122 removed from port 4 by  from console session
```

Syntax: show log

Enabling strict control of ACL filtering of fragmented packets

The default processing of fragments by hardware-based ACLs is as follows:

- The first fragment of a packet is permitted or denied using the ACLs. The first fragment is handled the same way as non-fragmented packets, since the first fragment contains the Layer 4 source and destination application port numbers. The device uses the Layer 4 CAM entry if one is programmed, or applies the interface's ACL entries to the packet and permits or denies the packet according to the first matching ACL.
- For other fragments of the same packet, they are subject to a rule only if there is no Layer 4 information in the rule or in any preceding rules.

The fragments are forwarded even if the first fragment, which contains the Layer 4 information, was denied. Generally, denying the first fragment of a packet is sufficient, since a transaction cannot be completed without the entire packet.

For tighter control, you can configure the port to drop all packet fragments. To do so, enter commands such as the following.

```
Brocade(config)#interface ethernet 1/1
Brocade(config-if-1/1)#ip access-group frag deny
```

This option begins dropping all fragments received by the port as soon as you enter the command. This option is especially useful if the port is receiving an unusually high rate of fragments, which can indicate a hacker attack.

Syntax: [no] ip access-group frag deny

Enabling ACL support for switched traffic in the router image

NOTE

The **bridged-routed** CLI parameter applies to FSX and FESX devices only. For FWS, Brocade FCX Series and ICX devices, ACL support for switched traffic in the router image is enabled by default. There is no command to enable or disable it.

For outbound traffic, ACL support is enabled on switched traffic by default. The **bridged-routed** command is not applicable.

By default, when an ACL is applied to a physical or virtual routing interface, the Brocade Layer 3 device filters routed traffic only. It does not filter traffic that is switched from one port to another within the same VLAN or virtual routing interface, even if an ACL is applied to the interface.

You can enable the device to filter switched traffic within a VLAN or virtual routing interface. When filtering is enabled, the device uses the ACLs applied to inbound traffic to filter traffic received by a port from another port in the same virtual routing interface.

To enable this feature, enter a command such as the following.

```
Brocade(config)# access-list 101 bridged-routed
```

Applying the ACL rule above to an interface enables filtering of traffic switched within a VLAN or virtual routing interface.

Syntax: [no] **access-list** <ACL-ID> **bridged-routed**

The <ACL-ID> parameter specifies a standard or extended numbered or named ACL.

You can use the **bridged-routed** feature in conjunction with **enable ACL-per-port-per-vlan**, to assign an ACL to certain ports of a VLAN under the virtual interface configuration level. In this case, all of the Layer 3 traffic (bridged and routed) are filtered by the ACL. The following shows an example configuration.

```
Brocade(config)#vlan 101 by port
Brocade(config-vlan-101)#tagged ethernet 1 to 4
Brocade(config-vlan-101)#router-interface ve 101
Brocade(config-vlan-101)#exit
Brocade(config)#enable ACL-per-port-per-vlan
Brocade(config)#access-list 101 bridged-routed
Brocade(config)#write memory
Brocade(config)#exit
Brocade#reload
...
Brocade(config-vif-101)#ip access group 1 in ethernet 1 ethernet 3 ethernet 4
```

NOTE

For FastIron X Series devices, the **enable ACL-per-port-per-vlan** command must be followed by the **write-memory** and **reload** commands to place the change into effect.

Enabling ACL filtering based on VLAN membership or VE port membership

NOTE

This section applies to IPv4 ACLs only. IPv6 ACLs do not support ACL filtering based on VLAN membership or VE port membership.

This feature is not applicable to outbound traffic.

You can apply an inbound IPv4 ACL to specific VLAN members on a port (Layer 2 devices only) or to specific ports on a virtual interface (VE) (Layer 3 Devices only). By default, this feature support is disabled. To enable it, enter the following commands at the Global CONFIG level of the CLI.

```
Brocade(config)#enable ACL-per-port-per-vlan
Brocade(config)#write memory
Brocade(config)#exit
Brocade#reload
```

NOTE

For complete configuration examples, see [“Applying an IPv4 ACL to specific VLAN members on a port \(Layer 2 devices only\)”](#) on page 1734 and [“Applying an IPv4 ACL to a subset of ports on a virtual interface \(Layer 3 devices only\)”](#) on page 1735.

NOTE

For FastIron X Series devices, you must save the configuration and reload the software to place the change into effect.

Syntax: [no] enable ACL-per-port-per-vlan

Enter the **no** form of the command to disable this feature.

Configuration notes for ACL filtering

- Before enabling this feature on an IPv4 device, make sure the VLAN numbers are contiguous. For example, the VLAN numbers can be 201, 202, 203, and 204, but not 300, 401, 600, and 900.
- Brocade devices do not support a globally-configured PBR policy together with per-port-per-VLAN ACLs.
- IPv4 ACLs that filter based on VLAN membership or VE port membership (ACL-per-port-per-VLAN), are supported together with IPv6 ACLs on the same device, as long as they are not bound to the same port or virtual interface.

Applying an IPv4 ACL to specific VLAN members on a port (Layer 2 devices only)

NOTE

This section applies to IPv4 ACLs only. IPv6 ACLs do not support ACL filtering based on VLAN membership.

When you bind an IPv4 ACL to a port, the port filters all inbound traffic on the port. However, on a tagged port, there may be a need to treat packets for one VLAN differently from packets for another VLAN. In this case, you can configure a tagged port on a Layer 2 device to filter packets based on the packets' VLAN membership.

To apply an IPv4 ACL to a specific VLAN on a port, enter commands such as the following.

```
Brocade(config)#enable ACL-per-port-per-vlan
...
Brocade(config)#vlan 12 name vlan12
Brocade(config-vlan-12)#untag ethernet 5 to 8
Brocade(config-vlan-12)#tag ethernet 23 to 24
Brocade(config-vlan-12)#exit
Brocade(config)#access-list 10 deny host 209.157.22.26 log
Brocade(config)#access-list 10 deny 209.157.29.12 log
Brocade(config)#access-list 10 deny host IPhost1 log
Brocade(config)#access-list 10 permit
Brocade(config)#int e 1/23
Brocade(config-if-e1000-1/23)#per-vlan 12
Brocade(config-if-e1000-1/23-vlan-12)#ip access-group 10 in
```

NOTE

For FastIron X Series devices, the **enable ACL-per-port-per-vlan** command must be followed by the **write-memory** and **reload** commands to place the change into effect. .

The commands in this example configure port-based VLAN 12, and add ports e 5 – 8 as untagged ports and ports e 23 – 24 as tagged ports to the VLAN. The commands following the VLAN configuration commands configure ACL 10. Finally, the last three commands apply ACL 10 on VLAN 12 for which port e 23 is a member.

Syntax: **per-vlan** <VLAN ID>

Syntax: **[no] ip access-group** <ACL ID>

The <VLAN ID> parameter specifies the VLAN name or number to which you will bind the ACL.

The <ACL ID> parameter is the access list name or number.

Applying an IPv4 ACL to a subset of ports on a virtual interface (Layer 3 devices only)

NOTE

This section applies to IPv4 ACLs only. IPv6 ACLs do not support ACL filtering based on VE port membership.

You can apply an IPv4 ACL to a virtual routing interface. The virtual interface is used for routing between VLANs and contains all the ports within the VLAN. The IPv4 ACL applies to all the ports on the virtual routing interface. You also can specify a subset of ports within the VLAN containing a specified virtual interface when assigning an ACL to that virtual interface.

Use this feature when you do not want the IPv4 ACLs to apply to all the ports in the virtual interface VLAN or when you want to streamline IPv4 ACL performance for the VLAN.

To apply an ACL to a subset of ports within a virtual interface, enter commands such as the following.

```
Brocade(config)#enable ACL-per-port-per-vlan
...
Brocade(config)#vlan 10 name IP-subnet-vlan
Brocade(config-vlan-10)#untag ethernet 1/1 to 2/12
Brocade(config-vlan-10)#router-interface ve 1
Brocade(config-vlan-10)#exit
Brocade(config)#access-list 1 deny host 209.157.22.26 log
Brocade(config)#access-list 1 deny 209.157.29.12 log
Brocade(config)#access-list 1 deny host IPhost1 log
Brocade(config)#access-list 1 permit any
Brocade(config)#interface ve 1/1
Brocade(config-vif-1/1)#ip access-group 1 in ethernet 1/1 ethernet 1/3 ethernet
2/1 to 2/4
```

NOTE

For FastIron X Series devices, the **enable ACL-per-port-per-vlan** command must be followed by the **write-memory** and **reload** commands to place the change into effect.

The commands in this example configure port-based VLAN 10, add ports 1/1 – 2/12 to the VLAN, and add virtual routing interface 1 to the VLAN. The commands following the VLAN configuration commands configure ACL 1. Finally, the last two commands apply ACL 1 to a subset of the ports associated with virtual interface 1.

Syntax: [no] **ip access-group** <ACL ID> **in ethernet** <port> [to <port>]

The <ACL ID> parameter is the access list name or number.

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

ACLs to filter ARP packets

NOTE

This feature is not applicable to outbound traffic.

You can use ACLs to filter ARP packets. Without this feature, ACLs cannot be used to permit or deny incoming ARP packets. Although an ARP packet contains an IP address just as an IP packet does, an ARP packet is not an IP packet; therefore, it is not subject to normal filtering provided by ACLs.

When a Brocade device receives an ARP request, the source MAC and IP addresses are stored in the device ARP table. A new record in the ARP table overwrites existing records that contain the same IP address. This behavior can cause a condition called "ARP hijacking", when two hosts with the same IP address try to send an ARP request to the Brocade device.

Normally ARP hijacking is not a problem because IP assignments are done dynamically; however, in some cases, ARP hijacking can occur, such as when a configuration allows a router interface to share the IP address of another router interface. Since multiple VLANs and the router interfaces that are associated with each of the VLANs share the same IP segment, it is possible for two hosts in two different VLANs to fight for the same IP address in that segment. ARP filtering using ACLs protects an IP host record in the ARP table from being overwritten by a hijacking host. Using ACLs to filter ARP requests checks the source IP address in the received ARP packet. Only packets with the permitted IP address will be allowed to be written in the ARP table; others are dropped.

Configuration considerations for filtering ARP packets

- This feature is available on devices running Layer 3 code. This filtering occurs on the management processor.
- The feature is available on physical interfaces and virtual routing interfaces. It is supported on the following physical interface types Ethernet and trunks.
- ACLs used to filter ARP packets on a virtual routing interface can be inherited from a previous interface if the virtual routing interface is defined as a follower virtual routing interface.

Configuring ACLs for ARP filtering

To implement the ACL ARP filtering feature, enter commands such as the following.

```
Brocade(config)# access-list 101 permit ip host 192.168.2.2 any
Brocade(config)# access-list 102 permit ip host 192.168.2.3 any
Brocade(config)# access-list 103 permit ip host 192.168.2.4 any
Brocade(config)# vlan 2
Brocade(config-vlan-2)# tag ethe 1/1 to 1/2
Brocade(config-vlan-2)# router-interface ve 2
Brocade(config-vlan-2)# vlan 3
Brocade(config-vlan-3)# tag ethe 1/1 to 1/2
Brocade(config-vlan-3)# router-int ve 3
Brocade(config-vlan-3)# vlan 4
Brocade(config-vlan-4)# tag ethe 1/1 to 1/2
Brocade(config-vlan-4)# router-int ve 4
Brocade(config-vlan-4)# interface ve 2
Brocade(config-ve-2)# ip access-group 101 in
Brocade(config-ve-2)# ip address 192.168.2.1/24
Brocade(config-ve-2)# ip use-ACL-on-arp 103
Brocade(config-ve-2)# exit
Brocade(config)# interface ve 3
Brocade(config-ve-3)# ip access-group 102 in
Brocade(config-ve-3)# ip follow ve 2
Brocade(config-ve-3)# ip use-ACL-on-arp
Brocade(config-ve-3)# exit
Brocade(config-vlan-4)# interface ve 4
Brocade(config-ve-4)# ip follow ve 2
Brocade(config-ve-4)# ip use-ACL-on-arp
Brocade(config-ve-4)# exit
```

Syntax: [no] ip use-ACL-on-arp [<access-list-number>]

When the **use-ACL-on-arp** command is configured, the ARP module checks the source IP address of the ARP request packets received on the interface. It then applies the specified ACL policies to the packet. Only the packet with the IP address that the ACL permits will be allowed to be written in the ARP table; those that are not permitted will be dropped.

The *<access-list-number>* parameter identifies the ID of the standard ACL that will be used to filter the packet. Only the source and destination IP addresses will be used to filter the ARP packet. You can do one of the following for *<access-list-number>*:

- Enter an ACL ID to explicitly specify the ACL to be used for filtering. In the example above, the line `FastIron(config-ve-2)# ip use-ACL-on-arp 103` specifies ACL 103 to be used as the filter.
- Allow the ACL ID to be inherited from the IP ACLs that have been defined for the device. In the example above, the line `FastIron(config-ve-4)# ip use-ACL-on-arp` allows the ACL to be inherited from IP ACL 101 because of the `ip follow` relationship between virtual routing interface 2 and virtual routing interface 4. Virtual routing interface 2 is configured with IP ACL 101; thus virtual routing interface 4 inherits IP ACL 101.

ARP requests will not be filtered by ACLs if one of the following conditions occur:

- If the ACL is to be inherited from an IP ACL, but there is no IP ACL defined.
- An ACL ID is specified for the `use-ACL-on-arp` command, but no IP address or “any any” filtering criteria have been defined under the ACL ID.

Displaying ACL filters for ARP

To determine which ACLs have been configured to filter ARP requests, enter a command such as the following.

```
Brocade(config)# show ACL-on-arp
Port ACL ID Filter Count
2 103 10
3 102 23
4 101 12
```

Syntax: `show ACL-on-arp [ethernet <port> | loopback [<num>] | ve [<num>]]`

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

If the *<port>* variable is not specified, all ports on the device that use ACLs for ARP filtering will be included in the display.

The Filter Count column shows how many ARP packets have been dropped on the interface since the last time the count was cleared.

Clearing the filter count

To clear the filter count for all interfaces on the device, enter a command such as the following.

```
Brocade(config)# clear ACL-on-arp
```

The above command resets the filter count on all interfaces in a device back to zero.

Syntax: `clear ACL-on-arp`

Filtering on IP precedence and ToS values

To configure an extended IP ACL that matches based on IP precedence, enter commands such as the following.

```
Brocade(config)#access-list 103 deny tcp 209.157.21.0/24 209.157.22.0/24
precedence internet
Brocade(config)#access-list 103 deny tcp 209.157.21.0/24 eq ftp 209.157.22.0/24
precedence 6
Brocade(config)#access-list 103 permit ip any any
```

The first entry in this ACL denies TCP traffic from the 209.157.21.x network to the 209.157.22.x network, if the traffic has the IP precedence option “internet” (equivalent to “6”).

The second entry denies all FTP traffic from the 209.157.21.x network to the 209.157.22.x network, if the traffic has the IP precedence value “6” (equivalent to “internet”).

The third entry permits all packets that are not explicitly denied by the other entries. Without this entry, the ACL would deny all incoming or outgoing IP traffic on the ports to which you assign the ACL.

To configure an IP ACL that matches based on ToS, enter commands such as the following.

```
Brocade(config)#access-list 104 deny tcp 209.157.21.0/24 209.157.22.0/24 tos
normal
Brocade(config)#access-list 104 deny tcp 209.157.21.0/24 eq ftp 209.157.22.0/24
tos 13
Brocade(config)#access-list 104 permit ip any any
```

The first entry in this IP ACL denies TCP traffic from the 209.157.21.x network to the 209.157.22.x network, if the traffic has the IP ToS option “normal” (equivalent to “0”).

The second entry denies all FTP traffic from the 209.157.21.x network to the 209.157.22.x network, if the traffic has the IP ToS value “13” (equivalent to “max-throughput”, “min-delay”, and “min-monetary-cost”).

The third entry permits all packets that are not explicitly denied by the other entries. Without this entry, the ACL would deny all incoming or outgoing IP traffic on the ports to which you assign the ACL.

TCP flags - edge port security

The edge port security feature works in combination with IP ACL rules and can be combined with other ACL functions (such as dscp-marking and traffic policies), giving you greater flexibility when designing ACLs.

For details about the edge port security feature, refer to [“Using TCP Flags in combination with other ACL features”](#) on page 178.

QoS options for IP ACLs

Quality of Service (QoS) options enable you to perform QoS for packets that match the ACLs. Using an ACL to perform QoS is an alternative to directly setting the internal forwarding priority based on incoming port, VLAN membership, and so on. (This method is described in [“QoS priorities-to-traffic assignment”](#) on page 1978.)

The following QoS ACL options are supported:

- **dscp-cos-mapping** – This option is similar to the **dscp-matching** command (described below). This option maps the DSCP value in incoming packets to a hardware table that provides mapping of each of the 0 – 63 DSCP values, and distributes them among eight traffic classes (internal priorities) and eight 802.1p priorities.

By default, the Brocade device does the *802.1p* to CoS mapping. If you want to change the priority mapping to *DSCP* to CoS mapping, you must enter the following ACL statement.

```
permit ip any any dscp-cos-mapping
```

- **dscp-marking** – Marks the DSCP value in the outgoing packet with the value you specify.
- **internal-priority-marking** and **802.1p-priority-marking** – Supported with the DSCP marking option, these commands assign traffic that matches the ACL to a hardware forwarding queue (**internal-priority-marking**), and re-mark the packets that match the ACL with the 802.1p priority (**802.1p-priority-marking**).
- **dscp-matching** – Matches on the packet DSCP value. This option does not change the packet forwarding priority through the device or mark the packet.
- **802.1p-priority-matching** – Inspects the 802.1p bit in the ACL that can be used with adaptive rate limiting. For details, refer to [“Inspecting the 802.1p bit in the ACL for adaptive rate limiting”](#) on page 1781.

NOTE

These QoS options are only available if a specific ICMP type is specified for the *<icmp-type>* parameter while configuring extended ACLs, and cannot be used with the **any-icmp-type** option. See [“Extended numbered ACL syntax”](#) on page 1714 and [“Extended named ACL syntax”](#) on page 1721 for the syntax for configuring extended ACLs.

Configuration notes for QoS options on FCX and ICX devices

- These devices do not support marking and prioritization simultaneously with the same rule (and do not support DSCP CoS mapping at all). To achieve this, you need to create two separate rules. In other words, you can mark a rule with DSCP or 802.1p information, or you can prioritize a rule based on DSCP or 802.1p information. You can enable only one of the following ACL options per rule:
 - 802.1p-priority-marking
 - dscp-marking
 - internal-priority-marking

For example, any one of the following commands is supported.

```
FastIron(config)#access-list 101 permit ip any any dscp-marking 43
```

or

```
FastIron(config)#access-list 101 permit ip any any 802.1p-priority-marking
```

or

```
FastIron(config)#access-list 101 permit ip any any internal-priority-marking 6
```

The following command is not supported.

```
FastIron(config)#access-list 101 permit ip any any dscp-marking 43
802.1p-priority-marking 4 internal-priority-marking 6
```

Using an ACL to map the DSCP value (DSCP CoS mapping)

NOTE

The **dscp-cos-mapping** option is supported on FSX and FESX devices only. It is not supported on Stackable devices. This feature is not applicable to outbound traffic.

The **dscp-cos-mapping** option maps the DSCP value in incoming packets to a hardware table that provides mapping of each of the 0 – 63 DSCP values, and distributes them among eight traffic classes (internal priorities) and eight 802.1p priorities.

NOTE

The **dscp-cos-mapping** option overrides port-based priority settings.

By default, the Brocade device does the 802.1p to CoS mapping. If you want to change the priority mapping to DSCP to CoS mapping, you must enter the following ACL statement.

```
permit ip any any dscp-cos-mapping
```

The complete CLI syntax for this feature is shown in [“Extended numbered ACL configuration”](#) on page 1714 and [“Extended named ACL configuration”](#) on page 1720. The following shows the syntax specific to the DSCP Cos mapping feature.

Syntax: ... [**dscp-marking** <dscp-value> **dscp-cos-mapping**]

or

Syntax: ...[**dscp-cos-mapping**]

NOTE

The **dscp-cos-mapping** option should not be used when assigning an 802.1p priority. To assign an 802.1p priority to a specific DSCP (using **dscp-match**), re-assign the DSCP value as well. For example

```
FastIron(config)#access-list 100 permit ip any any dscp-match 0 dscp-marking 0
802.1p 0 internal 1
```

Using an IP ACL to mark DSCP values (DSCP marking)

The **dscp-marking** option for extended ACLs allows you to configure an ACL that marks matching packets with a specified DSCP value. You also can use DSCP marking to assign traffic to a specific hardware forwarding queue (refer to [“Using an ACL to change the forwarding queue”](#) on page 1743).

For example, the following commands configure an ACL that marks all IP packets with DSCP value 5. The ACL is then applied to incoming packets on interface 7. Consequently, all inbound packets on interface 7 are marked with the specified DSCP value.

```
Brocade(config)#access-list 120 permit ip any any dscp-marking 5 dscp-cos-mapping
Brocade(config)#interface 1/7
Brocade(config-if-e1000-1/7)#ip access-group 120 in
```

Syntax: ...**dscp-marking** <dscp-value>

The **dscp-marking** <dscp-value> parameter maps a DSCP value to an internal forwarding priority. The DSCP value can be from 0 – 63.

NOTE

The **dscp-cos-mapping** option is supported on FESX and FSX devices only.

Combined ACL for 802.1p marking

Brocade devices support a simple method for assigning an 802.1p priority value to packets without affecting the actual packet or the DSCP. In early IronWare software releases, users were required to provide DSCP-marking and DSCP-matching information in order to assign 802.1p priority values, which required the deployment of a 64-line ACL to match all possible DSCP values. Users were also required to configure an internal priority marking value. Now, users can easily specify 802.1p priority marking values directly, and change internal priority marking from *required* to *optional*.

NOTE

This feature is not applicable to outbound traffic.

On the following devices, if the user does not set a specific internal marking priority, the default value is the same as the 802.1p-priority marking value:

- FWS, FCX, FESX, and ICX devices
- FastIron SX modules, with the exception of SX-48GCPP modules, released prior to hardware release 07.3.00, including:
 - SX-FI624C
 - SX-FI624HF
 - SX-FI62XG
 - SX-FI42XG
 - SX-FI424C
 - SX-FI424F
 - SX-FI8GMR6
 - SX-FI2XGMR4

On the following devices, if the user does not set a specific internal marking priority, then the internal priority does not change:

- SX-48GCPP modules
- All FastIron SX modules released in hardware release 07.3.00 and later releases, including:
 - SX-FI24GPP
 - SX-FI24HF
 - SX-FI2XG
 - SX-FI8XG

Priority values range from 0 to 7.

Two new ACL parameters support this feature, one required for priority marking and one optional for internal priority marking. These parameters apply to IP, and TCP, and UDP.

For IP

```
Brocade(config)#acc 104 per ip any any 802.1p-priority-marking 1
```

or the following command, which also assigns an optional internal-priority-marking value.

```
Brocade(config)#acc 104 per ip any any 802.1p-priority-marking 1
internal-priority-marking 5
```

Syntax: `access-list <num(100-199)> permit ip any any 802.1p-priority-marking <priority value (0-7)> [internal-priority-marking <value (0-7)>]`

For TCP

```
Brocade(config)#acc 105 per tcp any any 802.1p-priority-marking 1
```

or the following command, which also assigns an optional internal-priority-marking value.

```
Brocade(config)#acc 105 per tcp any any 802.1p-priority-marking 1
internal-priority-marking 5
```

Syntax: `access-list <num(100-199)> permit tcp any any 802.1p-priority-marking <priority value (0-7)> [internal-priority-marking <value (0-7)>]`

For UDP

```
Brocade(config) #acc 105 per udp any any 802.1p-priority-marking 1
```

or the following command, which also assigns an optional internal-priority-marking value.

```
Brocade(config) #acc 105 per udp any any 802.1p-priority-marking 1
internal-priority-marking 5
```

Syntax: `access-list <num(100-199)> permit udp any any 802.1p-priority-marking <priority value (0-7)> [internal-priority-marking <value (0-7)>]`

In each of these examples, in the first command the internal-priority value is not specified, which means it maintains a default value of 1 (equal to that of the 802.1p value). In the second command, the internal-priority value has been configured by the user to 5.

Using an ACL to change the forwarding queue

The **802.1p-priority-marking** <0 – 7> parameter re-marks the packets of the 802.1Q traffic that match the ACL with this new 802.1p priority, or marks the packets of the non-802.1Q traffic that match the ACL with this 802.1p priority, later at the outgoing 802.1Q interface.

The 802.1p priority mapping is shown in [Table 285](#).

The **internal-priority-marking** <0 – 7> parameter assigns traffic that matches the ACL to a specific hardware forwarding queue (qosp0 – qosp7>).

NOTE

The **internal-priority-marking** parameter overrides port-based priority settings.

On the FCX platform, using either **802.1p-priority-marking** or **802.1p-priority-marking** with **internal-priority-marking** performs both marking and internal prioritization.

In addition to changing the internal forwarding priority, if the outgoing interface is an 802.1Q interface, this parameter maps the specified priority to its equivalent 802.1p (CoS) priority and marks the packet with the new 802.1p priority. [Table 285](#) lists the default mappings of hardware forwarding queues to 802.1p priorities on the FESX and FSX.

TABLE 285 Default mapping of forwarding queues to 802.1p priorities

Forwarding queue	qosp0	qosp1	qosp2	qosp3	qosp4	qosp5	qosp6	qosp7
802.1p	0	1	2	3	4	5	6	7

The complete CLI syntax for 802.1p priority marking and internal priority marking is shown in [“Extended numbered ACL configuration”](#) on page 1714 and [“Extended named ACL configuration”](#) on page 1720. The following shows the syntax specific to these features.

Syntax: ... **dscp-marking** <0 – 63> **802.1p-priority-marking** <0 – 7> **internal-priority-marking** <0 – 7>]

DSCP matching

The **dscp-matching** option matches on the packet DSCP value. This option does not change the packet forwarding priority through the device or mark the packet.

To configure an ACL that matches on a packet with DSCP value 29, enter a command such as the following.

```
Brocade(config)#access-list 112 permit ip 1.1.1.0 0.0.0.255 2.2.2.x 0.0.0.255
dscp-matching 29
```

The complete CLI syntax for this feature is shown in [“Extended numbered ACL configuration”](#) on page 1714 and [“Extended named ACL configuration”](#) on page 1720. The following shows the syntax specific to this feature.

Syntax: ...**dscp-matching** <0 – 63>

NOTE

For complete syntax information, refer to [“Extended numbered ACL syntax”](#) on page 1714.

ACL-based rate limiting

ACL-based rate limiting provides the facility to limit the rate for IP traffic that matches the permit conditions in extended IP ACLs. This feature is available in the Layer 2 and Layer 3 code.

NOTE

Brocade devices support ACL-based rate limiting for inbound traffic. This feature is not supported for outbound traffic.

For more details, including configuration procedures, refer to [Chapter 42, “Traffic Policies”](#).

ACL statistics

ACL statistics is a mechanism for counting the number of packets and the number of bytes per packet to which ACL filters are applied.

To see the configuration procedures for ACL statistics, refer to [Chapter 42, “Traffic Policies”](#).

NOTE

The terms *ACL statistics* and *ACL counting* are used interchangeably in this guide and mean the same thing.

ACLs to control multicast features

You can use ACLs to control the following multicast features:

- Limit the number of multicast groups that are covered by a static rendezvous point (RP)
- Control which multicast groups for which candidate RPs sends advertisement messages to bootstrap routers
- Identify which multicast group packets will be forwarded or blocked on an interface

For configuration procedures, refer to [Chapter 36, “IP Multicast Protocols”](#).

Enabling and viewing hardware usage statistics for an ACL

The number of configured ACL rules can affect the rate at which hardware resources are used. You can use the **show access-list hw-usage on** command to enable hardware usage statistics, followed by the **show access-list <access-list-id>** command to determine the hardware usage for an ACL. To gain more hardware resources, you can modify the ACL rules so that it uses less hardware resource.

To enable and view hardware usage statistics, enter commands such as the following:

```
Brocade#show access-list hw-usage on
Brocade#show access-list 100
Extended IP access list 100 (hw usage : 2)
deny ip any any (hw usage : 1
```

The first command enables hardware usage statistics, and the second command displays the hardware usage for IP access list 100.

NOTE

Hardware usage statistics for ACLs differ for SX 800 and SX 1600 devices with one or more SX-FI48GPP interface modules, compared to devices that do not have this interface module.

The following displays an example of the show output for an SX 800 device in which an SX-FI48GPP interface module is installed.

```
Brocade#show access-list all
```

```
Standard IP access list 1 (hw usage (if applied on 24GC modules) : 2) (hw usage
(if applied on 48GC modules) : 2)
permit any (hw usage (if applied on 24GC modules) : 1) (hw usage (if applied on
48GC modules) : 1)
```

```
Extended IP access list 100 (hw usage (if applied on 24GC modules) : 7) (hw
usage (if applied on 48GC modules) : 7)
deny tcp any range newacct src any (hw usage (if applied on 24GC modules) : 6)
(hw usage (if applied on 48GC modules) : 6)
```

```
FastIron SX 800 Router#sh mod
```

Module	Status	Ports	Starting MAC
F1: SX-FISF Switch Fabric	active		
F2: SX-FISF Switch Fabric	active		
S1:			
S2:			
S3: Configured as SX-FI648 48-port 100/1000 Copper			
S4: SX-FI648PP 48-port 100/1000 Copper	OK	48	0012.f227.7918
S5: SX-FI624C 24-port Gig Copper	OK	24	0012.f227.7960
S6:			
S7: SX-FI624C 24-port Gig Copper	OK	24	0012.f227.7990
S8:			
S9: SX-FIZMR6 0-port Management	Standby	0	
{ Status : OK }			
S10: SX-FIZMR6 0-port Management	Active	0	
{ Status : OK }			

Syntax: show access-list hw-usage on | off

Syntax: show access-list <access-list-id> | all

By default, hardware usage statistics are disabled. To disable hardware usage statistics after is has been enabled, use the **show access-list hw-usage off** command.

The <access-list-id> variable is a valid ACL name or number.

Displaying ACL information

To display the number of Layer 4 CAM entries used by each ACL, enter the following command.

```
Brocade#show access-list all
```

```
Extended IP access list 100 (Total flows: N/A, Total packets: N/A, Total rule cam
use: 3)
permit udp host 192.168.2.169 any (Flows: N/A, Packets: N/A, Rule cam use: 1)
permit icmp any any (Flows: N/A, Packets: N/A, Rule cam use: 1)
deny ip any any (Flows: N/A, Packets: N/A, Rule cam use: 1)
```

Syntax: show access-list <ACL-num> | <ACL-name> | all

The Rule cam use field lists the number of CAM entries used by the ACL or entry. The number of CAM entries listed for the ACL itself is the total of the CAM entries used by the ACL entries.

For flow-based ACLs, the Total flows and Flows fields list the number of Layer 4 session table flows in use for the ACL.

The Total packets and Packets fields apply only to flow-based ACLs.

Troubleshooting ACLs

Use the following methods to troubleshoot access control lists (ACLs):

- To display the number of Layer 4 CAM entries being used by each ACL, enter the **show access-list <ACL-num> | <ACL-name> | all** command. Refer to [“Displaying ACL information”](#) on page 1746.
- To determine whether the issue is specific to fragmentation, remove the Layer 4 information (TCP or UDP application ports) from the ACL, then reapply the ACL.

If you are using another feature that requires ACLs, either use the same ACL entries for filtering and for the other feature, or change to flow-based ACLs.

Policy-based routing (PBR)

Policy-Based Routing (PBR) allows you to use ACLs and route maps to selectively modify and route IP packets in hardware. The ACLs classify the traffic. Route maps that match on the ACLs set routing attributes for the traffic.

A PBR policy specifies the next hop for traffic that matches the policy. Using standard ACLs with PBR, you can route IP packets based on their source IP address. With extended ACLs, you can route IP packets based on all of the clauses in the extended ACL.

You can configure the Brocade device to perform the following types of PBR based on a packet Layer 3 and Layer 4 information:

- Select the next-hop gateway.
- Send the packet to the null interface (null0).

When a PBR policy has multiple next hops to a destination, PBR selects the first live next hop specified in the policy that is up. If none of the policy's direct routes or next hops are available, the packet is routed in the normal way.

Configuration considerations for policy-based routing

- PBR is supported in the full Layer 3 code only.
- PBR is not supported on FastIron WS devices.
- PBR is not supported together with ACLs on the same port.
- Global PBR is not supported when IP Follow is configured on an interface.
- Global PBR is not supported with per-port-per-VLAN ACLs.
- A PBR policy on an interface takes precedence over a global PBR policy.
- You cannot apply PBR on a port if that port already has ACLs, ACL-based rate limiting, DSCP-based QoS, MAC address filtering.

- The number of route maps that you can define is limited by the available system memory, which is determined by the system configuration and how much memory other features use. When a route map is used in a PBR policy, the PBR policy uses up to six instances of a route map, up to five ACLs in a matching policy of each route map instance, and up to six next hops in a set policy of each route map instance. Note that the CLI will allow you configure more than six next hops in a route map; however, the extra next hops will not be placed in the PBR database. The route map could be used by other features like BGP or OSPF, which may use more than six next hops.
- ACLs with the **log** option configured should not be used for PBR purposes.
- PBR ignores explicit or implicit **deny ip any any** ACL entries, to ensure that for route maps that use multiple ACLs, the traffic is compared to all the ACLs. PBR also ignores any deny clauses in an ACL. Traffic that matches a deny clause is routed normally using Layer 3 paths.
- PBR always selects the first next hop from the next hop list that is up. If a PBR policy's next hop goes down, the policy uses another next hop if available. If no next hops are available, the device routes the traffic in the normal way.
- PBR is not supported for fragmented packets. If the PBR ACL filters on Layer 4 information like TCP/UDP ports, fragmented packets are routed normally.
- You can change route maps or ACL definitions dynamically and do not need to rebind the PBR policy to an interface.

Configuring a PBR policy

To configure PBR, you define the policies using IP ACLs and route maps, then enable PBR globally or on individual interfaces. The device programs the ACLs into the packet processor on the interfaces and routes traffic that matches the ACLs according to the instructions in the route maps.

To configure a PBR policy:

- Configure ACLs that contain the source IP addresses for the IP traffic you want to route using PBR.
- Configure a route map that matches on the ACLs and sets the route information.
- Apply the route map to an interface.

Configuring the ACLs

PBR uses route maps to change the routing attributes in IP traffic. This section shows an example of how to configure a standard ACL to identify the source subnet for IP traffic.

To configure a standard ACL to identify a source subnet, enter a command such as the following.

```
Brocade(config)#access-list 99 permit 209.157.23.0 0.0.0.255
```

The command in this example configures a standard ACL that permits traffic from subnet 209.157.23.0/24. After you configure a route map that matches based on this ACL, the software uses the route map to set route attributes for the traffic, thus enforcing PBR.

NOTE

Do not use an access group to apply the ACL to an interface. Instead, use a route map to apply the ACL globally or to individual interfaces for PBR, as shown in the following sections.

Syntax: [no]access-list <num> deny | permit <source-ip> | <hostname> <wildcard>

or

Syntax: `[no]access-list <num> deny | permit <source-ip>/<mask-bits> | <hostname>`

Syntax: `[no]access-list <num> deny | permit host <source-ip> | <hostname>`

Syntax: `[no]access-list <num> deny | permit any`

The `<num>` parameter is the access list number and can be from 1 – 99.

The **deny** | **permit** parameter indicates whether packets that match a policy in the access list are denied (dropped) or permitted (forwarded).

NOTE

If you are configuring the ACL for use in a route map, always specify **permit**. Otherwise, the Brocade device will ignore deny clauses and packets that match deny clauses are routed normally.

The `<source-ip>` parameter specifies the source IP address. Alternatively, you can specify the host name.

NOTE

To specify the host name instead of the IP address, the host name must be configured using the DNS resolver on the Brocade device. To configure the DNS resolver name, use the **ip dns server-address...** command at the global CONFIG level of the CLI.

The `<wildcard>` parameter specifies the mask value to compare against the host address specified by the `<source-ip>` parameter. The `<wildcard>` is in dotted-decimal notation (IP address format). It is a four-part value, where each part is 8 bits (one byte) separated by dots, and each bit is a one or a zero. Each part is a number ranging from 0 to 255, for example 0.0.0.255. Zeros in the mask mean the packet source address must match the `<source-ip>`. Ones mean any value matches. For example, the `<source-ip>` and `<wildcard>` values 209.157.22.26 0.0.0.255 mean that all hosts in the Class C subnet 209.157.22.x match the policy.

If you prefer to specify the wildcard (mask value) in CIDR format, you can enter a forward slash after the IP address, then enter the number of significant bits in the mask. For example, you can enter the CIDR equivalent of “209.157.22.26 0.0.0.255” as “209.157.22.26/24”. The CLI automatically converts the CIDR number into the appropriate ACL mask (where zeros instead of ones are the significant bits) and changes the non-significant portion of the IP address into zeros. For example, if you specify 209.157.22.26/24 or 209.157.22.26 0.0.0.255, then save the changes to the startup-config file, the value appears as 209.157.22.0/24 (if you have enabled display of subnet lengths) or 209.157.22.0 0.0.0.255 in the startup-config file.

If you enable the software to display IP subnet masks in CIDR format, the mask is saved in the file in “/`<mask-bits>`” format. To enable the software to display the CIDR masks, enter the **ip show-subnet-length** command at the global CONFIG level of the CLI. You can use the CIDR format to configure the ACL entry regardless of whether the software is configured to display the masks in CIDR format.

NOTE

If you use the CIDR format, the ACL entries appear in this format in the running-config and startup-config files, but are shown with subnet mask in the display produced by the **show ip access-list** command.

The **host** `<source-ip> | <hostname>` parameter lets you specify a host IP address or name. When you use this parameter, you do not need to specify the mask. A mask of all zeros (0.0.0.0) is implied.

The **any** parameter configures the policy to match on all host addresses.

NOTE

Do not use the **log** option in ACLs that will be used for PBR.

Configuring the route map

After you configure the ACLs, you can configure a PBR route map that matches based on the ACLs and sets routing information in the IP traffic.

NOTE

The match and set statements described in this section are the only route-map statements supported for PBR. Other route-map statements described in the documentation apply only to the protocols with which they are described.

To configure a PBR route map, enter commands such as the following.

```
Brocade(config)#route-map test-route permit 99
Brocade(config-route-map test-route)#match ip address 99
Brocade(config-route-map test-route)#set ip next-hop 192.168.2.1
Brocade(config-route-map test-route)#exit
```

The commands in this example configure an entry in a route map named “test-route”. The **match** statement matches on IP information in ACL 99. The **set** statement changes the next-hop IP address for packets that match to 192.168.2.1.

Syntax: [no]route-map <map-name> permit | deny <num>

The <map-name> is a string of characters that names the map. Map names can be up to 32 characters in length. You can define an unlimited number of route maps on the Brocade device, as long as system memory is available.

The **permit** | **deny** parameter specifies the action the Brocade device will take if a route matches a match statement:

- If you specify **deny**, the Brocade device does not apply a PBR policy to packets that match the ACLs in a match clause. Those packets are routed normally,
- If you specify **permit**, the Brocade device applies the match and set statements associated with this route map instance.

The <num> parameter specifies the instance of the route map you are defining. Routes are compared to the instances in ascending numerical order. For example, a route is compared to instance 1, then instance 2, and so on.

PBR uses up to six route map instances for comparison and ignores the rest.

Syntax: [no] match ip address <ACL-num-or-name>

The <ACL-num> parameter specifies a standard or extended ACL number or name.

Syntax: [no] set ip next hop <ip-addr>

This command sets the next-hop IP address for traffic that matches a match statement in the route map.

Syntax: [no] set interface null0

This command sends the traffic to the null0 interface, which is the same as dropping the traffic.

Enabling PBR

After you configure the ACLs and route map entries, you can enable PBR globally, on individual interfaces, or both as described in this section. To enable PBR, you apply a route map you have configured for PBR globally or locally.

Enabling PBR globally

To enable PBR globally, enter a command such as the following at the global CONFIG level.

```
Brocade(config)#ip policy route-map test-route
```

This command applies a route map named “test-route” to all interfaces on the device for PBR.

Syntax: `ip policy route-map <map-name>`

Enabling PBR locally

To enable PBR locally, enter commands such as the following.

```
Brocade(config)#interface ve 1
Brocade(config-vif-1)#ip policy route-map test-route
```

The commands in this example change the CLI to the Interface level for virtual interface 1, then apply the “test-route” route map to the interface. You can apply a PBR route map to Ethernet ports or virtual interfaces.

Syntax: `ip policy route-map <map-name>`

Enter the name of the route map you want to use for the route-map <map-name> parameter.

Configuration examples for policy based routing

This section presents configuration examples for configuring and applying a PBR policy.

Basic example of policy based routing

The following commands configure and apply a PBR policy that routes HTTP traffic received on virtual routing interface 1 from the 10.10.10.x/24 network to 5.5.5.x/24 through next-hop IP address 1.1.1.1/24 or, if 1.1.1.x is unavailable, through 2.2.2.1/24.

```
Brocade(config)#access-list 101 permit tcp 10.10.10.0 0.0.0.255 eq http 5.5.5.0
0.0.0.255
Brocade(config)#route-map net10web permit 101
Brocade(config-routemap net10web)#match ip address 101
Brocade(config-routemap net10web)#set ip next-hop 1.1.1.1
Brocade(config-routemap net10web)#set ip next-hop 2.2.2.2
Brocade(config-routemap net10web)#exit
Brocade(config)#vlan 10
Brocade(config-vlan-10)#tagged ethernet 1/1 to 1/4

Brocade(config-vlan-10)#router-interface ve 1
Brocade(config)#interface ve 1
Brocade(config-vif-1)#ip policy route-map net10web
```

Syntax: `[no] route-map <map-name> permit | deny <num>`

Syntax: `[no] set ip next hop <ip-addr>`

This command sets the next-hop IP address for traffic that matches a match statement in the route map.

Setting the next hop

The following commands configure the Brocade device to apply PBR to traffic from IP subnets 209.157.23.x, 209.157.24.x, and 209.157.25.x. In this example, route maps specify the next-hop gateway for packets from each of these subnets:

- Packets from 209.157.23.x are sent to 192.168.2.1.
- Packets from 209.157.24.x are sent to 192.168.2.2.
- Packets from 209.157.25.x are sent to 192.168.2.3.

The following commands configure three standard ACLs. Each ACL contains one of the ACLs listed above. Make sure you specify **permit** instead of deny in the ACLs, so that the Brocade device permits the traffic that matches the ACLs to be further evaluated by the route map. If you specify **deny**, the traffic that matches the deny statements are routed normally. Notice that these ACLs specify **any** for the destination address.

```
Brocade(config)#access-list 50 permit 209.157.23.0 0.0.0.255
Brocade(config)#access-list 51 permit 209.157.24.0 0.0.0.255
Brocade(config)#access-list 52 permit 209.157.25.0 0.0.0.255
```

The following commands configure three entries in a route map called “test-route”. The first entry (permit 50) matches on the IP address information in ACL 50 above. For IP traffic from subnet 209.157.23.0/24, this route map entry sets the next-hop IP address to 192.168.2.1.

```
Brocade(config)#route-map test-route permit 50
Brocade(config-route-map test-route)#match ip address 50
Brocade(config-route-map test-route)#set ip next-hop 192.168.2.1
Brocade(config-route-map test-route)#exit
```

The following commands configure the second entry in the route map. This entry (permit 51) matches on the IP address information in ACL 51 above. For IP traffic from subnet 209.157.24.0/24, this route map entry sets the next-hop IP address to 192.168.2.2.

```
Brocade(config)#route-map test-route permit 51
Brocade(config-route-map test-route)#match ip address 51
Brocade(config-route-map test-route)#set ip next-hop 192.168.2.2
Brocade(config-route-map test-route)#exit
```

The following commands configure the third entry in the test-route route map. This entry (permit 52) matches on the IP address information in ACL 52 above. For IP traffic from subnet 209.157.25.0/24, this route map entry sets the next-hop IP address to 192.168.2.3.

```
Brocade(config)#route-map test-route permit 52
Brocade(config-route-map test-route)#match ip address 52
Brocade(config-route-map test-route)#set ip next-hop 192.168.2.3
Brocade(config-route-map test-route)#exit
```

The following command enables PBR by globally applying the test-route route map to all interfaces.

```
Brocade(config)#ip policy route-map test-route
```

Alternatively, you can enable PBR on specific interfaces, as shown in the following example. The commands in this example configure IP addresses in the three source subnets identified in ACLs 50, 51, and 52, then apply route map test-route to the interface.

```
Brocade(config)#interface ve 1
Brocade(config-vif-1)#ip address 209.157.23.1/24
Brocade(config-vif-1)#ip address 209.157.24.1/24
Brocade(config-vif-1)#ip address 209.157.25.1/24
Brocade(config-vif-1)#ip policy route-map test-route
```

Setting the output interface to the null interface

The following commands configure a PBR policy to send all traffic from 192.168.1.204/32 to the null interface, thus dropping the traffic instead of forwarding it.

```
Brocade(config)#access-list 56 permit 209.168.1.204 0.0.0.0
```

The following commands configure an entry in a route map called “file-13”. The first entry (permit 56) matches on the IP address information in ACL 56 above. For IP traffic from the host 209.168.1.204/32, this route map entry sends the traffic to the null interface instead of forwarding it, thus sparing the rest of the network the unwanted traffic.

```
Brocade(config)#route-map file-13 permit 56
Brocade(config-routemap file-13)#match ip address 56
Brocade(config-routemap file-13)#set interface null0
Brocade(config-routemap file-13)#exit
```

The following command enables PBR by globally applying the route map to all interfaces.

```
Brocade(config)#ip policy route-map file-13
```

Alternatively, you can enable PBR on specific interfaces, as shown in the following example. The commands in this example configure IP addresses in the source subnet identified in ACL 56, then apply route map file-13 to the interface.

```
Brocade(config)#interface ethernet 3/11
Brocade(config-if-e10000-3/11)#ip address 192.168.1.204/32
Brocade(config-if-e10000-3/11)#ip policy route-map file-13
```

Trunk formation with PBR policy

When a trunk is formed, the PBR policy on the primary port applies to all the secondary ports. If a different PBR policy exists on a secondary port at the time of a trunk formation, that policy is overridden by the PBR policy on the primary port. If the primary port does not have a PBR policy, then the secondary ports will not have a PBR policy.

When a trunk is removed, the PBR policy that was applied to the trunk interface is unbound (removed) from former secondary ports. If global PBR is configured, the secondary ports adhere to the global PBR; otherwise, no PBR policy is bound to former secondary ports.

IPv6 ACLs

[Table 286](#) lists the individual Brocade FastIron switches and the IPv6 Access Control Lists (ACL) features they support. These features are supported in Brocade FastIron switches that can be configured as an IPv6 host in an IPv6 network, and in devices that support IPv6 routing. These features are supported in the Layer 2, base Layer 3, edge Layer 3, and full Layer 3 software images, except where explicitly noted.

TABLE 286 Supported IPv6 ACL features

Feature	FESX FSX 800 FSX 1600 ¹	FWS	FCX ¹	ICX 6610	ICX 6430 ICX 6450
IPv6 ACLs	Yes	No	Yes	Yes	Yes
Applying an IPv6 ACL to an interface	Yes	No	Yes	Yes	Yes
IPv6 ACL comment text	Yes	No	Yes	Yes	Yes
IPv6 ACL logging of denied packets	Yes	No	Yes	Yes	Yes

1. IPv6 ACLs are not supported on base Layer 3 software images on the FSX and FCX platforms

This chapter describes how Access Control Lists (ACLs) are implemented and configured on a Brocade FastIron IPv6 switch.

IPv6 ACL overview

Brocade devices support IPv6 Access Control Lists (ACLs) for inbound traffic filtering, as detailed in [Table 286](#). You can configure up to 100 IPv6 ACLs and, by default, up to a system-wide maximum of 4000 ACL rules. For example, you can configure one ACL with 4000 entries, two ACLs with 2000 and 2093 entries respectively (combining IPv4 and IPv6 ACLs), etc.

An IPv6 ACL is composed of one or more conditional statements that pose an action (permit or deny) if a packet matches a specified source or destination prefix. For FESX and FSX devices, there can be up to 1024 statements per port region, including IPv6, IPv4, MAC address filters, and default statements. For FCX devices, there can be up to 4096 statements per port region, including IPv6, IPv4, MAC address filters, and default statements. For ICX devices, there can be up to 1536 statements per port region, including IPv6, IPv4, MAC address filters, and default statements. When the maximum number of ACL rules allowed per port region is reached, an error message will display on the console.

In ACLs with multiple statements, you can specify a priority for each statement. The specified priority determines the order in which the statement appears in the ACL. The last statement in each IPv6 ACL is an implicit deny statement for all packets that do not match the previous statements in the ACL.

You can configure an IPv6 ACL on a global basis, then apply it to the incoming IPv6 packets on specified interfaces. You can apply only one IPv6 ACL to an interface. When an interface receives an IPv6 packet, it applies the statements within the ACL in their order of appearance to the packet. As soon as a match occurs, the Brocade device takes the specified action (permit or deny the packet) and stops further comparison for that packet.

IPv6 ACLs are supported on:

- Gbps Ethernet ports
- 10 Gbps Ethernet ports
- Trunk groups
- Virtual routing interfaces

NOTE

IPv6 ACLs are supported on inbound traffic and are implemented in hardware, making it possible for the Brocade device to filter traffic at line-rate speed on 10 Gbps interfaces.

IPv6 ACL traffic filtering criteria

The Brocade implementation of IPv6 ACLs enable traffic filtering based on the following information:

- IPv6 protocol
- Source IPv6 address
- Destination IPv6 address
- IPv6 message type
- Source TCP or UDP port (if the IPv6 protocol is TCP or UDP)
- Destination TCP or UDP port (if the IPv6 protocol is TCP or UDP)

IPv6 protocol names and numbers

The IPv6 protocol can be one of the following well-known names or any IPv6 protocol number from 0 – 255:

- Authentication Header (AHP)
- Encapsulating Security Payload (ESP)
- Internet Control Message Protocol (ICMP)
- Internet Protocol Version 6 (IPv6)
- Stream Control Transmission Protocol (SCTP)
- Transmission Control Protocol (TCP)
- User Datagram Protocol (UDP)

NOTE

TCP and UDP filters will be matched only if they are listed as the first option in the extension header.

For TCP and UDP, you also can specify a comparison operator and port name or number. For example, you can configure a policy to block web access to a specific website by denying all TCP port 80 (HTTP) packets from a specified source IPv6 address to the website IPv6 address.

IPv6 ACLs also provide support for filtering packets based on DSCP.

IPv6 ACL configuration notes

- IPv4 ACLs that filter based on VLAN membership or VE port membership (ACL-per-port-per-VLAN), are supported together with IPv6 ACLs on the same device, as long as they are not bound to the same port or virtual interface.
- IPv4 source guard and IPv6 ACLs are supported together on the same device, as long as they are not configured on the same port or virtual interface.
- IPv6 ACLs do not support ACL filtering based on VLAN membership or VE port membership.
- IPv6 ACLs cannot be used with GRE
- IPv6 ACLs cannot be employed to implement a user-based ACL scheme
- If an IPv6 ACL has the implicit **deny** condition, make sure it also **permits** the IPv6 link-local address, in addition to the global unicast address. Otherwise, routing protocols such as OSPF will not work. To view the link-local address, use the **show ipv6 interface** command.
- IPv6 must be enabled on the interface before an ACL can be applied to it. If IPv6 is not enabled on the interface, the system will display the following error message.

```
Brocade(config-if-e1000-7)#ipv6 traffic-filter netw in
Error: IPv6 is not enabled for interface 7
```

To enable IPv6 on an interface, enter **ipv6 enable** at the Interface level of the CLI, or assign an IPv6 address to the interface as described in [“IPv6 configuration on each router interface”](#) on page 362 and further discussed in [“Enabling IPv6 on an interface to which an ACL will be applied”](#) on page 1768.

- You cannot disable IPv6 on an interface to which an ACL is bound. Attempting to do so will cause the system to return the following error message.

```
Brocade(config-if-e1000-7)#no ipv6 enable
Error: Port 7 has IPv6 ACL configured. Cannot disable IPv6
```

To disable IPv6, first remove the ACL from the interface.

- For notes on applying IPv6 ACLs to trunk ports, see [“Applying an IPv6 ACL to a trunk group”](#) on page 1769.
- For notes on applying IPv6 ACLs to virtual ports, see [“Applying an IPv6 ACL to a virtual interface in a protocol-based or subnet-based VLAN”](#) on page 1769.
- The **dscp-cos-mapping** option is supported on FESX and FSX devices only.

Configuring an IPv6 ACL

Follow the steps given below to configure an IPv6 ACL.

1. Create the ACL.
2. Enable IPv6 on the interface to which the ACL will be applied.
3. Apply the ACL to the interface.

Example IPv6 configurations

To configure an access list that blocks all Telnet traffic received on port 1/1 from IPv6 host 2000:2382:e0bb::2, enter the following commands.

```
Brocade(config)# ipv6 access-list fdry
Brocade(config-ipv6-access-list-fdry)# deny tcp host 2000:2382:e0bb::2 any eq
telnet
Brocade(config-ipv6-access-list-fdry)# permit ipv6 any any
Brocade(config-ipv6-access-list-fdry)# exit
Brocade(config)# int eth 1/1
Brocade(config-if-1/1)# ipv6 enable
Brocade(config-if-1/1)# ipv6 traffic-filter fdry in
Brocade(config)# write memory
```

The following is another example of commands for configuring an ACL and applying it to an interface.

```
Brocade(config)# ipv6 access-list netw
Brocade(config-ipv6-access-list-netw)# permit icmp 2000:2383:e0bb::/64
2001:3782::/64
Brocade(config-ipv6-access-list-netw)# deny ipv6 host 2000:2383:e0ac::2 host
2000:2383:e0aa:0::24
Brocade(config-ipv6-access-list-netw)# deny udp any any
Brocade(config-ipv6-access-list-netw)# permit ipv6 any any
```

The first condition permits ICMP traffic from hosts in the 2000:2383:e0bb::x network to hosts in the 2001:3782::x network.

The second condition denies all IPv6 traffic from host 2000:2383:e0ac::2 to host 2000:2383:e0aa:0::24.

The third condition denies all UDP traffic.

The fourth condition permits all packets that are not explicitly denied by the other entries. Without this entry, the ACL would deny all incoming IPv6 traffic on the ports to which you assigned the ACL.

The following commands apply the ACL "netw" to the incoming traffic on port 1/2 and to the incoming traffic on port 4/3.

```
Brocade(config)# int eth 1/2
Brocade(config-if-1/2)# ipv6 enable
Brocade(config-if-1/2)# ipv6 traffic-filter netw in
Brocade(config-if-1/2)# exit
Brocade(config)# int eth 4/3
Brocade(config-if-4/3)# ipv6 enable
Brocade(config-if-4/3)# ipv6 traffic-filter netw in
Brocade(config)# write memory
```

Here is another example.

```
Brocade(config)# ipv6 access-list nextone
Brocade(config-ipv6-access-list rtr)# deny tcp 2001:1570:21::/24
2001:1570:22::/24
Brocade(config-ipv6-access-list rtr)# deny udp any range 5 6 2001:1570:22::/24
Brocade(config-ipv6-access-list rtr)# permit ipv6 any any
Brocade(config-ipv6-access-list rtr)# write memory
```

The first condition in this ACL denies TCP traffic from the 2001:1570:21::x network to the 2001:1570:22::x network.

The next condition denies UDP packets from any source with source UDP port in ranges 5 to 6 and whose destination is to the 2001:1570:22::/24 network.

The third condition permits all packets containing source and destination addresses that are not explicitly denied by the first two. Without this entry, the ACL would deny all incoming IPv6 traffic on the ports to which you assign the ACL.

A **show running-config** command displays the following.

```
Brocade(config)# show running-config
ipv6 access-list rtr
deny tcp 2001:1570:21::/24 2001:1570:22::/24
deny udp any range rje 6 2001:1570:22::/24
permit ipv6 any any
```

A **show ipv6 access-list** command displays the following.

```
Brocade(config)# sh ipv6 access-list rtr
ipv6 access-list rtr: 3 entries
10: deny tcp 2001:1570:21::/24 2001:1570:22::/24
20: deny udp any range rje 6 2001:1570:22::/24
30: permit ipv6 any any
```

The following commands apply the ACL “rtr” to the incoming traffic on ports 2/1 and 2/2.

```
Brocade(config)# int eth 2/1
Brocade(config-if-2/1)# ipv6 enable
Brocade(config-if-2/1)# ipv6 traffic-filter rtr in
Brocade(config-if-2/1)# exit
Brocade(config)# int eth 2/2
Brocade(config-if-2/2)# ipv6 enable
Brocade(config-if-2/2)# ipv6 traffic-filter rtr in
Brocade(config)# write memory
```

Default and implicit IPv6 ACL action

The default action when no IPv6 ACLs are configured on an interface is to permit all IPv6 traffic. However, once you configure an IPv6 ACL and apply it to an interface, the default action for that interface is to deny all IPv6 traffic that is not explicitly permitted on the interface.

- If you want to tightly control access, configure ACLs consisting of permit entries for the access you want to permit. The ACLs implicitly deny all other access.

- If you want to secure access in environments with many users, you might want to configure ACLs that consist of explicit deny entries, then add an entry to permit all access to the end of each ACL. The permit entry permits packets that are not denied by the deny entries.

Every IPv6 ACL has the following implicit conditions as its last match conditions.

- **permit icmp any any nd-na** – Allows ICMP neighbor discovery acknowledgements.
- **permit icmp any any nd-ns** – Allows ICMP neighbor discovery solicitations.
- **deny ipv6 any any** – Denies IPv6 traffic. You must enter a **permit ipv6 any any** as the last statement in the access-list if you want to permit IPv6 traffic that were not denied by the previous statements.

NOTE

If an IPv6 ACL has the implicit **deny** condition, make sure it also **permits** the IPv6 link-local address, in addition to the global unicast address. Otherwise, routing protocols such as OSPF will not work. To view the link-local address, use the **show ipv6 interface** command.

The conditions are applied in the order shown above, with **deny ipv6 any any** as the last condition applied.

For example, if you want to deny ICMP neighbor discovery acknowledgement, then permit any remaining IPv6 traffic, enter commands such as the following.

```
Brocade(config)# ipv6 access-list netw
Brocade(config-ipv6-access-list-netw)# permit icmp 2000:2383:e0bb::/64
2001:3782::/64
Brocade(config-ipv6-access-list-netw)# deny icmp any any nd-na
Brocade(config-ipv6-access-list-netw)# permit ipv6 any any
```

The first permit statement permits ICMP traffic from hosts in the 2000:2383:e0bb::x network to hosts in the 2001:3782::x network.

The deny statement denies ICMP neighbor discovery acknowledgement.

The last entry permits all packets that are not explicitly denied by the other entries. Without this entry, the ACL will deny all incoming IPv6 traffic on the ports to which you assigned the ACL.

Furthermore, if you add the statement **deny icmp any any** in the access list, then all neighbor discovery messages will be denied. You must explicitly enter the **permit icmp any any nd-na** and **permit icmp any any nd-ns** statements just before the **deny icmp** statement if you want the ACLs to permit neighbor discovery as in the example below.

```
Brocade(config)#ipv6 access-list netw
Brocade(config-ipv6-access-list-netw)#permit icmp 2000:2383:e0bb::/64
2001:3782::/64
Brocade(config-ipv6-access-list-netw)#permit icmp any any nd-na
Brocade(config-ipv6-access-list-netw)#permit icmp any any nd-ns
Brocade(config-ipv6-access-list-netw)#deny icmp any any
Brocade(config-ipv6-access-list-netw)#permit ipv6 any any
```

Creating an IPv6 ACL

Before an IPv6 ACL can be applied to an interface, it must first be created, and then IPv6 must be enabled on that interface.

To create an IPv6 ACL, enter commands such as the following:

```
Brocade(config)# ipv6 access-list fdry
Brocade(config-ipv6-access-list-fdry)# deny tcp host 2000:2382:e0bb::2 any eq
telnet
Brocade(config-ipv6-access-list-fdry)# permit ipv6 any any
Brocade(config-ipv6-access-list-fdry)# exit
```

This creates an access list that blocks all Telnet traffic from IPv6 host 2000:2382:e0bb::2.

Syntax for creating an IPv6 ACL

NOTE

The following features are not supported:

- **ipv6-operator flow-label**
- **ipv6-operator fragments** when any protocol is specified. The option "fragments" can be specified only when "permit/deny ipv6" is specified. If you specify "tcp" or any other protocol instead of "ipv6" the keyword, "fragments" cannot be used.
- **ipv6-operator routing** when any protocol is specified. (Same limitation as for **ipv6-operator fragments**)

When creating ACLs, use the appropriate syntax below for the protocol you are filtering.

For IPv6 and supported protocols other than ICMP, TCP, or UDP

Syntax: [no] ipv6 access-list <ACL name>

Syntax: permit | deny <protocol>
 <ipv6-source-prefix/prefix-length> | any | host <source-ipv6_address>
 <ipv6-destination-prefix/prefix-length> | any | host <ipv6-destination-address>
 [ipv6-operator [<value>]]
 [802.1p-priority-marking <number>]
 [dscp-marking <number> 802.1p-priority-marking <number> internal-priority-marking
 <number>] | [dscp-marking <dscp-value> dscp-cos-mapping] | [dscp-cos-mapping]

For ICMP

Syntax: [no] ipv6 access-list <ACL name>

Syntax: permit | deny icmp <ipv6-source-prefix/prefix-length> | any | host
 <source-ipv6_address>
 <ipv6-destination-prefix/prefix-length> | any | host <ipv6-destination-address>
 [ipv6-operator [<value>]]
 [[<icmp-type>][<icmp-code>]] | [<icmp-message>]
 [dscp-marking <number>]

```
[dscp-marking <dscp-value> dscp-cos-mapping]
[dscp-cos-mapping]
```

For TCP

Syntax: [no] ipv6 access-list <ACL name>

Syntax: permit | deny <tcp>
<ipv6-source-prefix/prefix-length> | any | host <source-ipv6_address> [tcp-udp-operator
[source-port-number]]
<ipv6-destination-prefix/prefix-length> | any | host <ipv6-destination-address>
[tcp-udp-operator [destination-port-number]]
[ipv6-operator [<value>]]
[802.1p-priority-matching <number>]
[dscp-marking <number> 802.1p-priority-marking <number> internal-priority-marking

TABLE 287 Syntax descriptions

IPv6 ACL arguments	Description
ipv6 access-list <ACL name>	Enables the IPv6 configuration level and defines the name of the IPv6 ACL. The <ACL name> can contain up to 199 characters and numbers, but cannot begin with a number and cannot contain any spaces or quotation marks.
permit	The ACL will permit (forward) packets that match a policy in the access list.
deny	The ACL will deny (drop) packets that match a policy in the access list.
icmp	Indicates the you are filtering ICMP packets.
protocol	The type of IPv6 packet you are filtering. You can specify a well-known name for some protocols whose number is less than 255. For other protocols, you must enter the number. Enter “?” instead of a protocol to list the well-known names recognized by the CLI. IPv6 protocols include AHP – Authentication Header ESP – Encapsulating Security Payload IPv6 – Internet Protocol version 6 SCTP – Stream Control Transmission Protocol
<ipv6-source-prefix>/<prefix-length>	The <ipv6-source-prefix>/<prefix-length> parameter specify a source prefix and prefix length that a packet must match for the specified action (deny or permit) to occur. You must specify the <ipv6-source-prefix> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <prefix-length> parameter as a decimal value. A slash mark (/) must follow the <ipv6-prefix> parameter and precede the <prefix-length> parameter.
<ipv6-destination-prefix>/<prefix-length>	The <ipv6-destination-prefix>/<prefix-length> parameter specify a destination prefix and prefix length that a packet must match for the specified action (deny or permit) to occur. You must specify the <ipv6-destination-prefix> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <prefix-length> parameter as a decimal value. A slash mark (/) must follow the <ipv6-prefix> parameter and precede the <prefix-length> parameter
any	When specified instead of the <ipv6-source-prefix>/<prefix-length> or <ipv6-destination-prefix>/<prefix-length> parameters, matches any IPv6 prefix and is equivalent to the IPv6 prefix::/0.
host	Allows you specify a host IPv6 address. When you use this parameter, you do not need to specify the prefix length. A prefix length of all128 is implied.
icmp-type	ICMP packets can be filtered by ICMP message type. The type is a number from 0 to 255.
icmp code	ICMP packets, which are filtered by ICMP message type can also be filtered by the ICMP message code. The code is a number from 0 to 255,
icmp-message	ICMP packets are filtered by ICMP messages. Refer to “ICMP message configurations” on page 1766 for a list of ICMP message types.
tcp	Indicates the you are filtering TCP packets.
udp	Indicates the you are filtering UDP packets.

TABLE 287 Syntax descriptions (Continued)

IPv6 ACL arguments	Description
<code><ipv6-source-prefix>/<prefix-length></code>	The <code><ipv6-source-prefix>/<prefix-length></code> parameter specify a source prefix and prefix length that a packet must match for the specified action (deny or permit) to occur. You must specify the <code><ipv6-source-prefix></code> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <code><prefix-length></code> parameter as a decimal value. A slash mark (/) must follow the <code><ipv6-prefix></code> parameter and precede the <code><prefix-length></code> parameter.
<code><ipv6-destination-prefix>/<prefix-length></code>	The <code><ipv6-destination-prefix>/<prefix-length></code> parameter specify a destination prefix and prefix length that a packet must match for the specified action (deny or permit) to occur. You must specify the <code><ipv6-destination-prefix></code> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <code><prefix-length></code> parameter as a decimal value. A slash mark (/) must follow the <code><ipv6-prefix></code> parameter and precede the <code><prefix-length></code> parameter.
any	When specified instead of the <code><ipv6-source-prefix>/<prefix-length></code> or <code><ipv6-destination-prefix>/<prefix-length></code> parameters, matches any IPv6 prefix and is equivalent to the IPv6 prefix::/0.
host	Allows you specify a host IPv6 address. When you use this parameter, you do not need to specify the prefix length. A prefix length of all 128 is implied.
tcp-udp-operator	<p>The <code><tcp-udp-operator></code> parameter can be one of the following:</p> <ul style="list-style-type: none"> • eq – The policy applies to the TCP or UDP port name or number you enter after eq. • gt – The policy applies to TCP or UDP port numbers greater than the port number or the numeric equivalent of the port name you enter after gt. Enter "?" to list the port names. • lt – The policy applies to TCP or UDP port numbers that are less than the port number or the numeric equivalent of the port name you enter after lt. • neq – The policy applies to all TCP or UDP port numbers except the port number or port name you enter after neq. • range – The policy applies to all TCP port numbers that are between the first TCP or UDP port name or number and the second one you enter following the range parameter. The range includes the port names or numbers you enter. For example, to apply the policy to all ports between and including 23 (Telnet) and 53 (DNS), enter the following range 23 53. The first port number in the range must be lower than the last number in the range. <p>The <code><source-port number></code> and <code><destination-port number></code> for the tcp-udp-operator is the number of the port.</p>

TABLE 287 Syntax descriptions (Continued)

IPv6 ACL arguments	Description
ipv6-operator	<p>Allows you to filter the packets further by using one of the following options:</p> <ul style="list-style-type: none"> • dscp – The policy applies to packets that match the traffic class value in the traffic class field of the IPv6 packet header. This operator allows you to filter traffic based on TOS or IP precedence. You can specify a value from 0 – 63. • fragments – The policy applies to fragmented packets that contain a non-zero fragment offset. <p>NOTE: This option is not applicable to filtering based on source or destination port, TCP flags, and ICMP flags.</p> <ul style="list-style-type: none"> • routing – The policy applies only to IPv6 source-routed packets. <p>NOTE This option is not applicable to filtering based on source or destination port, TCP flags, and ICMP flags.</p>
802.1p-priority-matching <i><number></i>	<p>Enables the device to match only those packets that have the same 802.1p priorities as specified in the ACL. Enter 0 – 7.</p> <p>Use this option in conjunction with traffic policies to rate limit traffic for a specified 802.1p priority value. For details, refer to “Inspecting the 802.1p bit in the ACL for adaptive rate limiting” on page 1781.</p>
dscp-marking <i><number></i>	<p>Use the dscp-marking <i><number></i> parameter to specify a new QoS value to the packet. If a packet matches the filters in the ACL statement, this parameter assigns the DSCP value that you specify to the packet. Enter 0 – 63.</p>
802.1p-priority-marking <i><number></i>	<p>Use the 802.1p-priority-marking <i><number></i> parameter to specify a new QoS value to the packet (0-7). If a packet matches the filters in the ACL statement, the following actions happen:</p> <ul style="list-style-type: none"> • On FSX devices, this parameter assigns the 802.1p priority that you specify to the packet. • On all platforms other than FSX, this parameter assigns the priority that you specify to the 802.1p priority and the internal priority.
internal-priority-marking <i><number></i>	<p>Use the internal-priority-marking <i><number></i> parameter to specify a new QoS value to the packet (0-7). If a packet matches the filters in the ACL statement, the following actions happen:</p> <ul style="list-style-type: none"> • On FSX devices, this parameter assigns the internal priority that you specify to the packet. • On all platforms other than FSX, this parameter assigns the priority that you specify to the internal priority and the 802.1p priority. <p>NOTE: On all platforms other than FSX, configuring 802.1p-priority-marking alone or configuring both 802.1p-priority-marking and internal-priority-marking has the same functionality. That is, it assigns the priority that you specify to the 802.1p priority and the internal priority.</p>

TABLE 287 Syntax descriptions (Continued)

IPv6 ACL arguments	Description
dscp-marking <number>	Use the dscp-marking <number> dscp-cos-mapping parameters parameters to specify a DSCP value and map that value to an internal QoS table to obtain the packet new QoS value. The following occurs when you use these parameters. <ul style="list-style-type: none"> You enter 0 – 63 for the dscp-marking <number> parameter. The dscp-cos-mapping parameter takes the DSCP value you specified and compares it to an internal QoS table, which is indexed by DSCP values. The corresponding 802.1p priority, internal forwarding priority, and DSCP value is assigned to the packet.
dscp-cos-mapping ¹	Use dscp-cos-mapping if you want to use the DSCP value in the packet header to alter its QoS value. When you enter dscp-cos-mapping , the DSCP value in the packet header is compared to a column in the internal QoS table. The 802.1p priority, internal forwarding priority, and DSCP value that are mapped to the matching column is assigned to the packet.

1. **dscp-cos-mapping** is supported on FESX and FSX devices only.

ICMP message configurations

If you want to specify an ICMP message, you can enter one of the following ICMP message types:

- beyond-scope
- destination-unreachable
- echo-reply
- echo-request
- header
- hop-limit
- mld-query
- mld-reduction
- mld-report
- nd-na
- nd-ns
- next-header
- no-admin
- no-route
- packet-too-big
- parameter-option
- parameter-problem
- port-unreachable
- reassembly-timeout
- renum-command
- renum-result
- renum-seq-number
- router-advertisement

- router-renumbering
- router-solicitation
- time-exceeded
- unreachable

NOTE

If you do not specify a message type, the ACL applies to all types ICMP messages types.

Enabling IPv6 on an interface to which an ACL will be applied

Before an IPv6 ACL can be applied to an interface, it must first be created, and then IPv6 must be enabled on that interface.

To enable IPv6 on an interface, enter **ipv6 enable** at the Interface level of the CLI, or assign an IPv6 address to the interface, as described in [“IPv6 configuration on each router interface”](#) on page 362.

For example:

```
Brocade(config)#interface ethernet 1/1
Brocade(config-if-1/1)#ipv6 enable
```

These commands enable IPv6 on Ethernet interface 1/1 ready for an IPv6 ACL to be applied.

Syntax for enabling IPv6 on an interface

Syntax: **ipv6 enable**

When issued at the Interface Configuration level, this command enables IPv6 for a specific interface.

Applying an IPv6 ACL to an interface

As mentioned in [“IPv6 ACL overview”](#) on page 1755, IPv6 ACLs are supported on the following devices:

- Gbps Ethernet ports
- 10 Gbps Ethernet ports
- Trunk groups
- Virtual routing interfaces

To apply an IPv6 ACL to an interface, enter commands such as the following.

```
Brocade(config)#interface ethernet 3/1
Brocade(config-if-e100-3/1)#ipv6 traffic-filter access1 in
```

This example applies the IPv6 ACL “access1” to incoming IPv6 packets on Ethernet interface 3/1. As a result, Ethernet interface 3/1 denies all incoming packets from the site-local prefix fec0:0:0:2::/64 and the global prefix 2001:100:1::/48 and permits all other incoming packets.

Syntax for applying an IPv6 ACL

NOTE

The **ipv6 traffic-filter** *<ipv6-ACL-name>* **in** command is supported on FCX, ICX 6610, ICX 6430, ICX 6450, and FESX devices only. The command is not supported on FSX, FLS, FGS, and FWS devices.

Syntax: **ipv6 traffic-filter** *<ipv6-ACL-name>* **in**

For the *<ipv6-ACL-name>* parameter, specify the name of an IPv6 ACL created using the **ipv6 access-list** command.

The **in** keyword applies the specified IPv6 ACL to incoming IPv6 packets on the interface.

Applying an IPv6 ACL to a trunk group

When applying an IPv6 ACL to a trunk group, apply it to the primary port of the trunk, as described under [“Applying an IPv6 ACL to an interface”](#) on page 1768. IPv6 ACLs cannot be applied to secondary ports. When an IPv6 ACL is applied to a primary port in a trunk, it filters the traffic on the secondary ports of the trunk as well as the traffic on the primary port.

Applying an IPv6 ACL to a virtual interface in a protocol-based or subnet-based VLAN

As with IPv4 ACLs, by default, when you apply an IPv6 ACL to a virtual interface in a protocol-based or subnet-based VLAN, the ACL takes effect on all protocol or subnet VLANs to which the untagged port belongs. To prevent the Brocade device from denying packets on other virtual interfaces that do not have an ACL applied, configure an ACL that permits packets in the IP subnet of the virtual interface in all protocol-based or subnet-based VLANs to which the untagged port belongs.

Adding a comment to an IPv6 ACL entry

You can optionally add a comment to describe entries in an IPv6 ACL. The comment appears in the output of **show** commands that display ACL information.

You can add a comment by entering the **remark** command immediately preceding an ACL entry. For example, to enter comments preceding an ACL entry, enter commands such as the following.

```
Brocade(config)#ipv6 access-list rtr
Brocade(config-ipv6-access-list rtr)# remark This entry permits ipv6 packets from
3002::2 to any destination
Brocade(config-ipv6-access-list rtr)# permit ipv6 host 3000::2 any
Brocade(config-ipv6-access-list rtr)# remark This entry denies udp packets from
any source to any destination
Brocade(config-ipv6-access-list rtr)# deny udp any any
Brocade(config-ipv6-access-list rtr)# remark This entry denies IPv6 packets from
any source to any destination
Brocade(config-ipv6-access-list rtr)# deny ipv6 any any
Brocade(config-ipv6-access-list rtr)# write memory
```

Syntax: **remark** *<comment-text>*

The *<comment-text>* can be up to 256 characters in length.

Deleting a comment from an IPv6 ACL entry

The following shows the comment text for the ACL named "rtr" in a **show running-config** display.

```
Brocade#show running-config
ipv6 access-list rtr
  remark This entry permits ipv6 packets from 3002::2 to any destination
  permit ipv6 host 3000::2 any
  remark This entry denies udp packets from any source to any destination
  deny udp any any
  remark This entry denies IPv6 packets from any source to any destination
  deny ipv6 any any
```

Syntax: **show running-config**

Deleting a comment from an IPv6 ACL entry

To delete a comment from an IPv6 ACL entry, enter commands such as the following.

```
Brocade(config)#ipv6 access-list rtr
Brocade(config-ipv6-access-list rtr)#no remark This entry permits ipv6 packets
from 3002::2 to any destination
```

Syntax: **no remark** *<comment-text>*

For *<comment-text>*, enter the text exactly as you did when you created the comment.

Support for ACL logging

Brocade devices support ACL logging of inbound packets that are sent to the CPU for processing (denied packets). ACL logging is not supported for any packets that are processed in hardware (permitted packets).

You may want the software to log entries in the Syslog for packets that are denied by ACL filters. ACL logging is disabled by default; it must be explicitly enabled on a port. Refer to [“ACL logging”](#) on page 1729.

Displaying IPv6 ACLs

To display the IPv6 ACLs configured on a device, enter the **show ipv6 access-list** command. Here is an example.

```

Brocade#show ipv6 access-list
ipv6 access-list v6-ACL1: 1 entries
  deny ipv6 any any
ipv6 access-list v6-ACL2: 1 entries
  permit ipv6 any any
ipv6 access-list v6-ACL3: 2 entries
  deny ipv6 2001:aa:10::/64 any
  permit ipv6 any any
ipv6 access-list v6-ACL4: 2 entries
  deny ipv6 2002:aa::/64 any
  permit ipv6 any any
ipv6 access-list rate-ACL: 1 entries
  permit ipv6 any any traffic-policy rate800M
ipv6 access-list v6-ACL5: 8 entries
  permit tcp 2002:bb::/64 any
  permit ipv6 2002:bb::/64 any
  permit ipv6 2001:aa:101::/64 any
  permit ipv6 2001:aa:10::/64 2001:aa:102::/64
  permit ipv6 host 2001:aa:10::102 host 2001:aa:101::102
  permit ipv6 host 2001:aa:10::101 host 2001:aa:101::101 dscp-matching 0
  dscp-marking 63 dscp-cos-mapping
  permit ipv6 any any dscp-matching 63 dscp-cos-mapping
  permit ipv6 any any fragments

```

Syntax: show ipv6 access-list

To display a specific IPv6 ACL configured on a device, enter the **show ipv6 access-list** command followed by the ACL name. The following example shows the ACL named "rtr".

```

Brocade#show ipv6 access-list rtr
ipv6 access-list rtr: 3 entries
  remark This entry permits ipv6 packets from 3002::2 to any destination
  permit ipv6 host 3000::2 any
  remark This entry denies udp packets from any source to any destination
  deny udp any any
  remark This entry denies IPv6 packets from any source to any destination
  deny ipv6 any any

```

Syntax: show ipv6 access-list [<access-list-name>]

For the <access-list-name> parameter, specify the name of an IPv6 ACL created using the **ipv6 access-list** command.

Displaying IPv6 ACLs

Traffic Policies

Table 288 lists the individual Brocade FastIron switches and the traffic policy features they support. These features are supported in the Layer 2, base Layer 3, edge Layer 3, and full Layer 3 software images, except where explicitly noted.

TABLE 288 Supported traffic policy features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
Traffic policies	Yes	Yes	Yes	Yes	Yes
ACL-based fixed rate limiting	Yes	Yes	Yes	Yes	Yes
ACL-based adaptive rate limiting	Yes	No	Yes	Yes	Yes
802.1p priority bit inspection in the ACL for adaptive rate limiting	Yes (IPv6 devices only)	No	Yes	Yes	Yes
ACL statistics	Yes	Yes	Yes	Yes	Yes. ICX 6430 does not support creating a policy that only counts packets.
CPU rate-limiting	Yes	Yes	Yes	Yes	Yes

Traffic policies overview

This chapter describes how traffic policies are implemented and configured on the FastIron devices.

Brocade devices use traffic policies for the following reasons:

- To rate limit inbound traffic
- To count the packets and bytes per packet to which ACL permit or deny clauses are applied

Traffic policies consist of policy names and policy definitions:

- Traffic policy name – A string of up to eight alphanumeric characters that identifies individual traffic policy definitions.
- Traffic policy definition (TPD) – The command filter associated with a traffic policy name. A TPD can define any one of the following:
 - Rate limiting policy

- ACL counting policy
- Combined rate limiting and ACL counting policy

The maximum number of supported active TPDs is a system-wide parameter and depends on the device you are configuring. The total number of active TPDs cannot exceed the system maximum. Refer to [“Maximum number of traffic policies supported on a device”](#) on page 1775.

When you apply a traffic policy to an interface, you do so by adding a reference to the traffic policy in an ACL entry, instead of applying the individual traffic policy to the interface. The traffic policy becomes an active traffic policy or active TPD when you bind its associated ACL to an interface.

To configure traffic policies for ACL-based rate limiting, refer to [“Configuring ACL-based fixed rate limiting”](#) on page 1777 and [“ACL-based adaptive rate limiting configuration”](#) on page 1778.

To configure traffic policies for ACL counting, refer to [“Enabling ACL statistics”](#) on page 1783.

Configuration notes and feature limitations for traffic policies

Note the following when configuring traffic policies:

- Traffic policies applies to IP ACLs only.
- Traffic policies are supported on FastIron X Series devices, but not on the 10 Gbps Ethernet interfaces of the SX-FI62XG and SX-FI42XG modules.
- The maximum number of supported active TPDs is a system-wide parameter and depends on the device you are configuring. The total number of active TPDs cannot exceed the system maximum. Refer to [“Maximum number of traffic policies supported on a device”](#) on page 1775.
- You can reference the same traffic policy in more than one ACL entry within an ACL. For example, two or more ACL statements in ACL 101 can reference a TPD named TPD1.
- You can reference the same traffic policy in more than one ACL. For example, ACLs 101 and 102 could both reference a TPD named TPD1.
- To modify or delete an active traffic policy, you must first unbind the ACL that references the traffic policy.
- When you define a TPD (when you enter the CLI command **traffic-policy**), explicit marking of CoS parameters, such as traffic class and 802.1p priority, are not available on the device. In the case of a TPD defining rate limiting, the device re-marks CoS parameters based on the DSCP value in the packet header and the determined conformance level of the rate limited traffic, as shown in [Table 289](#).

TABLE 289 CoS parameters for packets that use rate limiting traffic policies

Packet conformance level	Packet DSCP value	Traffic class and 802.1p priority
0 (Green) or 1 (Yellow)	0 – 7	0 (lowest priority queue)
	8 – 15	1
	16 – 23	2
	24 – 31	3
	32 – 39	4
	40 – 47	5
	48 – 55	6
	56 – 63	7 (highest priority queue)
2 (Red)	N/A	0 (lowest priority queue)

- When you define a TPD, reference the TPD in an ACL entry, and then apply the ACL to a VE in the Layer 3 router code, the rate limit policy is accumulative for all of the ports in the port region. If the VE or VLAN contains ports that are in different port regions, the rate limit policy is applied per port region.

For example, TPD1 has a rate limit policy of 600M and is referenced in ACL 101. ACL 101 is applied to VE 1, which contains ports e 1/11 to e 1/14. Because ports e 1/11 and 1/12 are in a different port region than e 1/13 and 1/14, the rate limit policy will be 600M for ports e 1/11 and 1/12, and 600M for ports e 1/13 and 1/14.

Maximum number of traffic policies supported on a device

The maximum number of supported active traffic policies is a system-wide parameter and depends on the device you are configuring, as follows:

- By default, up to 1024 active traffic policies are supported on Layer 2 switches. This value is fixed on Layer 2 switches and cannot be modified.
- For FastIron devices other than the FCX, the number of active traffic policies supported on Layer 3 switches varies depending on the configuration and the available system memory. The default value and also the maximum number of traffic policies supported on Layer 3 switches is 50.
- On FCX devices, up to 1024 active traffic policies are supported on Layer 3 switches. This is the default value as well as the maximum value.

NOTE

On FCX devices, by default 992 of the maximum of 1024 active traffic policies are applied. The other 32 are reserved and the **show traff** command returns zero references/bindings beyond the 992 traffic policies.

The **show default values** command displays the maximum number of traffic conditioners that can be applied, in the *hw-traffic-conditioner* section of the results. The configurable tables and their defaults and maximum values can be obtained using the **show default** command.

Setting the maximum number of traffic policies supported on a Layer 3 device

NOTE

This configuration is supported on FastIron devices with the exception of the FCX platforms. Setting the system-max for traffic policies is not required on FCX platforms as the default number of traffic policies is also the maximum number.

If desired, you can adjust the maximum number of active traffic policies that a Layer 3 device will support. To do so, enter commands such as the following at the global CONFIG level of the CLI.

```
Brocade(config)#system-max hw-traffic-conditioner 25
Brocade(config)#write memory
Brocade(config)#reload
```

NOTE

You must save the configuration and reload the software to place the change into effect.

Syntax: [no] **system-max hw-traffic-conditioner** <num>

The <num> variable is a value from 0 through *n*, where 0 disables hardware resources for traffic policies, and *n* is a number up to 50. The maximum number you can configure depends on the configuration and available memory on your device. If the configuration you enter causes the device to exceed the available memory, the device will reject the configuration and display a warning message on the console.

NOTE

Brocade does not recommend setting the system maximum for traffic policies to 0 (zero), because this renders traffic policies ineffective.

ACL-based rate limiting using traffic policies

ACL-based rate limiting provides the facility to limit the rate for IP traffic that matches the permit conditions in extended IP ACLs. This feature is available in the Layer 2 and Layer 3 code.

To configure ACL-based rate limiting, you create individual traffic policies, and then reference the traffic policies in one or more ACL entries (also called *clauses* or *statements*). The traffic policies become effective on ports to which the ACLs are bound.

When you configure a traffic policy for rate limiting, the device automatically enables rate limit counting, similar to the two-rate three-color marker (trTCM) mechanism described in RFC 2698 for adaptive rate limiting, and the single-rate three-color marker (srTCM) mechanism described in RFC 2697 for fixed rate limiting. This feature counts the number of bytes and trTCM or srTCM conformance level per packet to which rate limiting traffic policies are applied. Refer to [“ACL statistics and rate limit counting”](#) on page 1782.

You can configure ACL-based rate limiting on the following interface types:

- Physical Ethernet interfaces
- Virtual interfaces
- Trunk ports

- Specific VLAN members on a port (refer to [“Applying an IPv4 ACL to specific VLAN members on a port \(Layer 2 devices only\)”](#) on page 1734)
- A subset of ports on a virtual interface (refer to [“Applying an IPv4 ACL to a subset of ports on a virtual interface \(Layer 3 devices only\)”](#) on page 1735)

Support for fixed rate limiting and adaptive rate limiting

NOTE

ACL-based fixed rate limiting is supported on all FastIron devices. ACL-based adaptive rate limiting is supported on FastIron X Series and Brocade FCX Series devices only. It is not supported on FastIron WS devices.

FastIron devices support the following types of ACL-based rate limiting:

- Fixed rate limiting – Enforces a strict bandwidth limit. The device forwards traffic that is within the limit but either drops all traffic that exceeds the limit, or forwards all traffic that exceeds the limit at the lowest priority level, according to the action specified in the traffic policy.
- Adaptive rate limiting – Enforces a flexible bandwidth limit that allows for bursts above the limit. You can configure adaptive rate limiting to forward traffic, modify the IP precedence of and forward traffic, or drop traffic based on whether the traffic is within the limit or exceeds the limit.

Configuring ACL-based fixed rate limiting

Use the procedures in this section to configure ACL-based fixed rate limiting. Before configuring this feature, see what to consider in [“Configuration notes and feature limitations for traffic policies”](#) on page 1774.

Fixed rate limiting enforces a strict bandwidth limit. The port forwards traffic that is within the limit. If the port receives more than the specified number of fragments in a one-second interval, the device either drops or forwards subsequent fragments in hardware, depending on the action you specify.

To implement the ACL-based fixed rate limiting feature, first create a traffic policy, and then reference the policy in an extended ACL statement. Lastly, bind the ACL to an interface. Complete the following steps.

1. Create a traffic policy. Enter a command such as the following.

```
Brocade(config)#traffic-policy TPD1 rate-limit fixed 100 exceed-action drop
```

2. Create an extended ACL entry or modify an existing extended ACL entry that references the traffic policy. Enter a command such as the following.

```
Brocade(config)#access-list 101 permit ip host 210.10.12.2 any traffic-policy TPD1
```

3. Bind the ACL to an interface. Enter commands such as the following.

```
Brocade(config)#interface ethernet 5
Brocade(config-if-e5)#ip access-group 101 in
Brocade(config-if-e5)#exit
```

The previous commands configure a fixed rate limiting policy that allows port e5 to receive a maximum traffic rate of 100 kbps. If the port receives additional bits during a given one-second interval, the port drops the additional inbound packets that are received within that one-second interval.

Syntax: [no] **traffic-policy** <TPD name> **rate-limit fixed** <cir value> **exceed-action** <action> [count]

Syntax: **access-list** <num> **permit** | **deny**.... **traffic policy** <TPD name>

Syntax: [no] **ip access-group** <num> **in**

NOTE

For brevity, some parameters were omitted from the **access-list** syntax.

The software allows you to add a reference to a non-existent TPD in an ACL statement and to bind that ACL to an interface. The software does not issue a warning or error message for non-existent TPDs.

Use the **no** form of the command to delete a traffic policy definition. Note that you cannot delete a traffic policy definition if it is currently in use on a port. To delete a traffic policy, first unbind the associated ACL.

The **traffic-policy** <TPD name> parameter is the name of the traffic policy definition. This value can be eight or fewer alphanumeric characters.

The **rate-limit fixed** <cir value> parameter specifies that the traffic policy will enforce a strict bandwidth. The <cir value> variable is the committed information rate in kbps. This value can be from 64 through 1,000,000 Kbps.

The **exceed-action** <action> parameter specifies the action to be taken when packets exceed the configured committed information rate (CIR) value. Refer to [“Specifying the action to be taken for packets that are over the limit”](#) on page 1781.

The **count** parameter is optional and enables ACL counting. Refer to [“ACL statistics and rate limit counting”](#) on page 1782.

ACL-based adaptive rate limiting configuration

NOTE

ACL-based adaptive rate limiting is supported on FastIron X Series and Brocade FCX Series devices. It is not supported on FastIron WS devices.

Use the procedures in this section to configure ACL-based adaptive rate limiting. Before configuring this feature, see what to consider in [“Configuration notes and feature limitations for traffic policies”](#) on page 1774.

[Table 290](#) lists the configurable parameters for ACL-based adaptive rate limiting.

TABLE 290 ACL based adaptive rate limiting parameters

Parameter	Definition
Committed Information Rate (CIR)	The guaranteed kilobit rate of inbound traffic that is allowed on a port.
Committed Burst Size (CBS)	The number of bytes per second allowed in a burst before some packets will exceed the committed information rate. Larger bursts are more likely to exceed the rate limit. The CBS must be a value greater than zero (0). Brocade recommends that this value be equal to or greater than the size of the largest possible IP packet in a stream.
Peak Information Rate (PIR)	The maximum kilobit rate for inbound traffic on a port. The PIR must be equal to or greater than the CIR.
Peak Burst Size (PBS)	The number of bytes per second allowed in a burst before all packets will exceed the peak information rate. The PBS must be a value greater than zero (0). Brocade recommends that this value be equal to or greater than the size of the largest possible IP packet in the stream.

If a port receives more than the configured bit or byte rate in a one-second interval, the port will either drop or forward subsequent data in hardware, depending on the action you specify.

Configuring ACL-based adaptive rate limiting

To implement the ACL-based adaptive rate limiting feature, first create a traffic policy, and then reference the policy in an extended ACL statement. Lastly, bind the ACL to an interface. Complete the following steps.

1. Create a traffic policy. Enter a command such as the following.

```
Brocade(config)#traffic-policy TPDfour rate-limit adaptive cir 10000 cbs 1600
pir 20000 pbs 4000 exceed-action drop
```

2. Create a new extended ACL entry or modify an existing extended ACL entry that references the traffic policy. Enter a command such as the following.

```
Brocade(config)#access-list 104 permit ip host 210.10.12.2 any traffic-policy
TPDfour
```

3. Bind the ACL to an interface. Enter commands such as the following.

```
Brocade(config)#interface ethernet 7
Brocade(config-if-e7)#ip access-group 104 in
Brocade(config-if-e7)#exit
```

The previous commands configure an adaptive rate limiting policy that enforces a guaranteed committed rate of 10000 kbps on port e7 and allows bursts of up to 1600 bytes. It also enforces a peak rate of 20000 kbps and allows bursts of 4000 bytes above the PIR limit. If the port receives additional bits during a given one-second interval, the port drops all packets on the port until the next one-second interval starts.

Syntax: [no] **traffic-policy** <TPD name> **rate-limit adaptive cir** <cir value> **cbs** <cbs value> **pir** <pir value> **pbs** <pbs value> **exceed-action** <action> [count]

Syntax: **access-list** <num> **permit | deny.... traffic policy** <TPD name>

Syntax: [no] **ip access-group** <num> **in**

NOTE

For brevity, some parameters were omitted from the **access-list** syntax.

The software allows you to add a reference to a non-existent TPD in an ACL statement and to bind that ACL to an interface. The software does not issue a warning or error message for non-existent TPDs.

Use the **no** form of the command to delete a traffic policy definition. Note that you cannot delete a traffic policy definition if it is currently in use on a port. To delete a traffic policy, first unbind the associated ACL.

The **traffic-policy** *<TPD name>* parameter is the name of the traffic policy definition. This value can be eight or fewer alphanumeric characters.

The **rate-limit adaptive cir** *<cir value>* specifies that the policy will enforce a flexible bandwidth limit that allows for bursts above the limit. The *<cir value>* variable is the committed information rate in kbps. Refer to [Table 290](#).

The **cbs** *<cbs value>* parameter is the committed burst size in bytes. Refer to [Table 290](#).

The **pir** *<pir value>* parameter is the peak information rate in kbps. Refer to [Table 290](#).

The **pbs** *<pbs value>* parameter is the peak burst size in bytes. Refer to [Table 290](#).

The **exceed-action** *<action>* parameter specifies the action to be taken when packets exceed the configured values. Refer to [“Specifying the action to be taken for packets that are over the limit”](#) on page 1781.

The **count** parameter is optional and enables ACL counting. Refer to [“ACL statistics and rate limit counting”](#) on page 1782.

Inspecting the 802.1p bit in the ACL for adaptive rate limiting

NOTE

This feature is supported on FastIron X Series IPv6 devices and Brocade FCX Series devices only. It is *not* supported on FastIron WS Series devices.

You can configure the Brocade device to rate limit traffic for a specified 802.1p priority value. To do so, complete the following configuration steps.

1. Create an adaptive rate limiting traffic policy. Enter command such as the following:

```
Brocade(config)#traffic-policy adap rate-limit adaptive cir 1000 cbs 1000 pir
2000 pbs 10000 exceed-action drop
```

2. Create an IPv4 extended ACL or IPv6 ACL that includes the traffic policy and 802.1p priority matching value. Enter a command such as the following:

```
Brocade(config)#access-list 136 permit ip any any 802.1p-priority matching 3
traffic-policy adap
```

3. Bind the ACL to an interface. Enter commands such as the following,.

```
Brocade(config)#interface ethernet 7
Brocade(config-if-e7)#ip access-group 136 in
Brocade(config-if-e7)#exit
```

Use the **show access-list accounting** command to view accounting statistics. For more information, refer to [“Viewing ACL and rate limit counters”](#) on page 1784.

Specifying the action to be taken for packets that are over the limit

You can specify the action to be taken when packets exceed the configured CIR value for fixed rate limiting, or the CIR, CBS, PIR, and PBS values for adaptive rate limiting. You can specify one of the following actions:

- Drop packets that exceed the limit.
- Permit packets that exceed the limit and forward them at the lowest priority level.

Dropping packets that exceed the limit

This section shows some example configurations and provides the CLI syntax for configuring a port to drop packets that exceed the configured limits for rate limiting.

The following example shows a fixed rate limiting configuration.

```
Brocade(config)#traffic-policy TPD1 rate-limit fixed 10000 exceed-action drop
```

The command sets the fragment threshold at 10,000 packet fragments per second. If the port receives more than 10,000 packet fragments in a one-second interval, the device drops the excess fragments.

Syntax: [no] traffic-policy <TPD name> rate-limit fixed <cir value> exceed-action drop

The following example shows an adaptive rate limiting configuration.

```
Brocade(config)#traffic-policy TPDfour rate-limit adaptive cir 10000 cbs 1600
pir 20000 pbs 4000 exceed-action drop
```

The command configures an adaptive rate limiting policy that enforces a guaranteed committed rate of 10000 kbps and allows bursts of up to 1600 bytes. It also enforces a peak rate of 20000 kbps and allows bursts of 4000 bytes above the PIR limit. If the port receives additional bits during a given one-second interval, the port drops all packets on the port until the next one-second interval starts.

Syntax: **[no] traffic-policy** <TPD name> **rate-limit adaptive cir** <cir value> **cbs** <cbs value> **pir** <pir value> **pbs** <pbs value> **exceed-action drop**

Permitting packets that exceed the limit

This section shows some example configurations and provides the CLI syntax for configuring a port to permit packets that exceed the configured limit for rate limiting.

The following example shows a fixed rate limiting configuration.

```
Brocade(config)#traffic-policy TPD1 rate-limit fixed 10000 exceed-action
permit-at-low-pri
```

The command sets the fragment threshold at 10,000 packet fragments per second. If the port receives more than 10,000 packet fragments in a one-second interval, the device takes the specified action. The action specified with this command is to permit excess fragments and forward them at the lowest priority level.

Syntax: **[no] traffic-policy** <TPD name> **rate-limit fixed** <cir value> **exceed-action permit-at-low-pri**

The following example shows an adaptive rate limiting configuration.

```
Brocade(config)#traffic-policy TPDfour rate-limit adaptive cir 10000 cbs 1600
pir 20000 pbs 4000 exceed-action permit-at-low-pri
```

The command configures an adaptive rate limiting policy that enforces a guaranteed committed rate of 10000 kbps and allows bursts of up to 1600 bytes. It also enforces a peak rate of 20000 kbps and allows bursts of 4000 bytes above the PIR limit. If the port receives additional bits during a given one-second interval, the port permits all packets on the port and forwards the packets at the lowest priority level.

Syntax: **[no] traffic-policy** <TPD name> **rate-limit adaptive cir** <cir value> **cbs** <cbs value> **pir** <pir value> **pbs** <pbs value> **exceed-action permit-at-low-pri**

ACL statistics and rate limit counting

ACL statistics, also called *ACL counting*, enables the Brocade device to count the number of packets and the number of bytes per packet to which ACL filters are applied.

Rate limit counting counts the number of bytes and the conformance level per packet to which rate limiting traffic policies are applied. The device uses the counting method similar to the two-rate three-color marker (trTCM) mechanism described in RFC 2698 for adaptive rate limiting, and the single-rate three-color marker (srTCM) mechanism described in RFC 2697 for fixed rate limiting. Rate limit counting is automatically enabled when a traffic policy is enforced (active). You can view these counters using the **show** commands listed in [“Viewing traffic policies”](#) on page 1786.

Enabling ACL statistics

NOTE

ACL statistics and ACL counting are used interchangeably throughout this chapter and mean the same thing.

NOTE

The FastIron WS does not support the use of traffic policies for ACL statistics only. However, these models do support the use of traffic policies for ACL statistics together with rate limiting traffic policies. Refer to [“Enabling ACL statistics with rate limiting traffic policies”](#) on page 1784.

Use the procedures in this section to configure ACL statistics. Before configuring ACL statistics, see what to consider in [“Configuration notes and feature limitations for traffic policies”](#) on page 1774.

To enable ACL statistics on a FastIron X Series device, first create a traffic policy, and then reference the traffic policy in an extended ACL entry. Lastly, bind the ACL to an interface. The ACL counting policy becomes effective on ports to which the ACLs are bound.

You also can enable ACL statistics when you create a traffic policy for rate limiting. Refer to [“Enabling ACL statistics with rate limiting traffic policies”](#) on page 1784.

Complete the following steps to implement the ACL statistics feature.

1. Create a traffic policy. Enter a command such as the following.

```
Brocade(config)#traffic-policy TPD5 count
```

2. Create an extended ACL entry or modify an existing extended ACL entry that references the traffic policy definition. Enter a command such as the following.

```
Brocade(config)#access-list 101 permit ip host 210.10.12.2 any traffic-policy TPD5
```

3. Bind the ACL to an interface. Enter commands such as the following.

```
Brocade(config)#interface ethernet 4
Brocade(config-if-e4)#ip access-group 101 in
Brocade(config-if-e4)#exit
```

The previous commands configure an ACL counting policy and apply it to port e4. Port e4 counts the number of packets and the number of bytes on the port that were permitted or denied by ACL filters.

Syntax: [no] traffic-policy <TPD name> count

Syntax: access-list <num> permit | deny.... traffic policy <TPD name>

Syntax: [no] ip access-group <num> in

NOTE

For brevity, some parameters were omitted from the **access-list** syntax.

The software allows you to add a reference to a non-existent TPD in an ACL statement and to bind that ACL to an interface. The software does not issue a warning or error message for non-existent TPDs.

Use the **no** form of the command to delete a traffic policy definition. Note that you cannot delete a traffic policy definition if it is currently in use on a port. To delete a traffic policy, first unbind the associated ACL.

The `<TPD name>` variable is the name of the traffic policy definition. This value can be eight alphanumeric characters or less.

Enabling ACL statistics with rate limiting traffic policies

The configuration example in the section “[Enabling ACL statistics](#)” on page 1783 shows how to enable ACL counting without having to configure parameters for rate limiting. You also can enable ACL counting while defining a rate limiting traffic policy, as illustrated in the following configuration examples.

To enable ACL counting while defining traffic policies for fixed rate limiting, enter commands such as the following at the global CONFIG level of the CLI.

```
Brocade(config)#traffic-policy TPD1 rate-limit fixed 1000 count
Brocade(config)#traffic-policy TPD2 rate-limit fixed 10000 exceed-action drop
count
```

Syntax: `[no] traffic-policy <TPD name> rate-limit fixed <cir value> count`

Syntax: `[no] traffic-policy <TPD name> rate-limit fixed <cir value> exceed-action <action> count`

To enable ACL counting while defining traffic policies for adaptive rate limiting, enter commands such as the following at the global CONFIG level of the CLI.

```
Brocade(config)#traffic-policy TPDA4 rate-limit adaptive cir 10000 cbs 1600 pir
20000 pbs 4000 count
Brocade(config)#traffic-policy TPDA5 rate-limit adaptive cir 10000 cbs 1600 pir
20000 pbs 4000 exceed-action permit-at-low-pri count
```

Syntax: `[no] traffic-policy <TPD name> rate-limit adaptive cir <cir value> cbs <cbs value> pir <pir value> pbs <pbs value> count`

Syntax: `[no] traffic-policy <TPD name> rate-limit adaptive cir <cir value> cbs <cbs value> pir <pir value> pbs <pbs value> exceed-action <action> count`

Viewing ACL and rate limit counters

When ACL counting is enabled on the Brocade device, you can use **show** commands to display the total packet count and byte count of the traffic filtered by ACL statements. The output of the **show** commands also displays the rate limiting traffic counters, which are automatically enabled for active rate limiting traffic policies.

Use either the **show access-list accounting traffic-policy** command or the **show statistics traffic-policy** command to display ACL and traffic policy counters. The outputs of these commands is identical.

NOTE

In the SX-FI48GPP module only, the outputs of these commands are identical with one exception. When ACL counting is shown by **show statistics traffic-policy**, the Packet Count is not supported and displays “N/A”.

The following example shows the output from the **show access-list accounting** command.

```
Brocade#show access-list accounting traffic-policy g_voip
```

```
Traffic Policy - g_voip:
```

```
General Counters:
```

Port Region#	Byte Count	Packet Count
7 (4/1 - 4/12)	85367040	776064
All port regions	84367040	776064

```
Rate Limiting Counters:
```

Port Region#	Green Conformance	Yellow Conformance	Red Conformance
7 (4/1 - 4/12)	329114195612139520	37533986897781760	0
All port regions	329114195612139520	37533986897781760	0

Syntax: `show access-list accounting traffic-policy [<TPD name>]`

or

Syntax: `show statistics traffic-policy [<TPD name>]`

The `<TPD name>` variable is the name of the traffic policy definition for which you want to display ACL and traffic policy counters.

[Table 291](#) explains the output of the `show access-list accounting traffic-policy` and `show statistics traffic-policy` commands.

TABLE 291 ACL and rate limit counting statistics

Parameter	Description
Traffic Policy	The name of the traffic policy.
General Counters	
Port Region #	The port region to which the active traffic policy applies.
Byte Count	The number of bytes that were filtered (matched ACL clauses).
Packet Count	The number of packets that were filtered (matched ACL clauses).
Rate Limiting Counters	
Port Region#	The port region to which the active traffic policy applies.
Green Conformance	The number of bytes that did not exceed the CIR packet rate.
Yellow Conformance	The number of bytes that exceeded the CIR packet rate.
Red Conformance	The number of bytes that exceeded the PIR packet rate.

Clearing ACL and rate limit counters

The Brocade device keeps a running tally of the number of packets and the number of bytes per packet that are filtered by ACL statements and rate limiting traffic policies. You can clear these accumulated counters, essentially resetting them to zero. To do so, use either the `clear access-list accounting traffic-policy` command or the `clear statistics traffic-policy` command.

To clear the counters for ACL counting and rate limit counting, enter commands such as the following.

```
Brocade(config)#clear access-list accounting traffic-policy CountOne
```

```
Brocade(config)#clear statistics traffic-policy CountTwo
```

Syntax: `clear access-list accounting traffic-policy <TPD name>`

or

Syntax: `clear statistics traffic-policy <TPD name>`

The `<TPD name>` is the name of the traffic policy definition for which you want to clear traffic policy counters.

Viewing traffic policies

To view traffic policies that are currently defined on the Brocade device, enter the **show traffic-policy** command. The following example shows displayed output. [Table 292](#) explains the output of the **show traffic-policy** command.

```
Brocade#show traffic-policy t_voip
Traffic Policy - t_voip:
Metering Enabled, Parameters:
      Mode: Adaptive Rate-Limiting
      cir: 100 kbps,      cbs: 2000 bytes,      pir: 200 kbps,      pbs: 4000
bytes
Counting Not Enabled
Number of References/Bindings:1
```

Syntax: `show traffic-policy [<TPD name>]`

To display all traffic policies, enter the **show traffic-policy** command without entering a TPD name.

TABLE 292 Traffic policy information

Parameter	Description
Traffic Policy	The name of the traffic policy.
Metering	Shows whether or not rate limiting was configured as part of the traffic policy: <ul style="list-style-type: none"> • Enabled – The traffic policy includes a rate limiting configuration. • Disabled – The traffic policy does not include a rate limiting configuration.
Mode	If rate limiting is enabled, this field shows the type of metering enabled on the port: <ul style="list-style-type: none"> • Fixed Rate-Limiting • Adaptive Rate-Limiting
cir	The committed information rate, in kbps, for the adaptive rate limiting policy.
cbs	The committed burst size, in bytes per second, for the adaptive rate- limiting policy.
pir	The peak information rate, in kbps, for the adaptive rate limiting policy.
pbs	The peak burst size, in bytes per second, for the adaptive rate limiting policy.
Counting	Shows whether or not ACL counting was configured as part of the traffic policy: <ul style="list-style-type: none"> • Enabled – Traffic policy includes an ACL counting configuration. • Disabled – Traffic policy does not include an ACL traffic counting configuration.
Number of References/Bindings	NOTE: This field does not apply to FastIron X Series devices. The number of port regions to which this traffic policy applies. For example, if the traffic policy is applied to a trunk group that includes ports e 9/9, 9/10, 9/11, and 9/12, the value in this field would be 2, because these four trunk ports are in two different port regions.

CPU rate-limiting

Unnecessary traffic to the switch CPU lowers the efficiency of the CPU and delays handling of other traffic that requires processing. CPU rate limiting is a CPU protection scheme which limits certain traffic types.

CPU rate limiting identifies the traffic type and assigns a maximum rate limit to the traffic type. The traffic types which are subjected to rate limiting include broadcast ARP and other exceptions, such as TTL exceed, IP MTU failed, reverse path check failed, IP fragments, and unsupported tunneling. Each of these types is rate-limited individually.

[Table 293](#) shows the rate limits for each rate-limited packet type and shows which platforms on which each rate limit applies. These rates cannot be configured by users currently.

TABLE 293 CPU rate limits for packet type and applicable platforms

Packet type	Rate limit in packets per second	Applicable platforms
ARP	6000	All
IP TTL exceed, or Reverse path check failed	150	All
IP MTU exceed, IP tunnel-terminated packets which are fragmented or has options, or IP tunnel-terminated packets with unsupported GRE tunnel header	3000	All
IP Unicast packets mirrored to CPU due to ICMP redirect	100	All
Bridge packets forward to CPU	5000	FCX and ICX

All currently supported FastIron devices support the CPU rate-limiting feature. However, on the FSX devices, only the following modules support this feature:

- SX-FI-24GPP
- SX-FI-24HF
- SX-FI-2XG
- SX-FI-8XG
- SX-FI48GPP

CPU rate-limiting

802.1X Port Security

Table 294 lists individual Brocade switches and the 802.1X port security features they support. These features are supported in the Layer 2, base Layer 3, edge Layer 3, and full Layer 3 software images, except where explicitly noted.

TABLE 294 Supported 802.1X port security features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
802.1X port security	Yes	Yes	Yes	Yes	Yes
Multiple host authentication	Yes	Yes	Yes	Yes	Yes
EAP pass-through support	Yes	Yes	Yes	Yes	Yes
802.1X accounting	Yes	Yes	Yes	Yes	Yes
802.1X dynamic assignment for ACL, MAC address filter, and VLAN	Yes	Yes	Yes	Yes	Yes
Automatic removal of Dynamic VLAN for 802.1X ports	Yes	Yes	Yes	Yes	Yes
RADIUS timeout action	Yes	Yes	Yes	Yes	Yes
802.1X and multi-device port authentication on the same port	Yes	Yes	Yes	Yes	Yes
802.1X and sFlow <ul style="list-style-type: none"> 802.1X username export support for encrypted and non-encrypted EAP types 	Yes	Yes	Yes	Yes	Yes

IETF RFC support

Brocade FastIron devices support the IEEE 802.1X standard for authenticating devices attached to LAN ports. Using 802.1X port security, you can configure a FastIron device to grant access to a port based on information supplied by a client to an authentication server.

When a user logs on to a network that uses 802.1X port security, the Brocade device grants (or does not grant) access to network services after the user is authenticated by an authentication server. The user-based authentication in 802.1X port security provides an alternative to granting network access based on a user IP address, MAC address, or subnetwork.

The Brocade implementation of 802.1X port security supports the following RFCs:

- RFC 2284 PPP Extensible Authentication Protocol (EAP)
- RFC 2865 Remote Authentication Dial In User Service (RADIUS)
- RFC 2869 RADIUS Extensions

How 802.1X port security works

This section explains the basic concepts behind 802.1X port security, including device roles, how the devices communicate, and the procedure used for authenticating clients.

NOTE

802.1X Port Security cannot be configured on MAC Port Security-enabled ports.

Device roles in an 802.1X configuration

The 802.1X standard defines the roles of *Client/Supplicant*, *Authenticator*, and *Authentication Server* in a network.

The Client (known as a **Supplicant** in the 802.1X standard) provides username/password information to the Authenticator. The Authenticator sends this information to the Authentication Server. Based on the Client's information, the Authentication Server determines whether the Client can use services provided by the Authenticator. The Authentication Server passes this information to the Authenticator, which then provides services to the Client, based on the authentication result.

[Figure 188](#) illustrates these roles.

FIGURE 188 Authenticator, client/supplicant, and authentication server in an 802.1X configuration

Authenticator – The device that controls access to the network. In an 802.1X configuration, the Brocade device serves as the Authenticator. The Authenticator passes messages between the Client and the Authentication Server. Based on the identity information supplied by the Client, and the authentication information supplied by the Authentication Server, the Authenticator either grants or does not grant network access to the Client.

Client/Supplicant – The device that seeks to gain access to the network. Clients must be running software that supports the 802.1X standard (for example, the Windows XP operating system). Clients can either be directly connected to a port on the Authenticator, or can be connected by way of a hub.

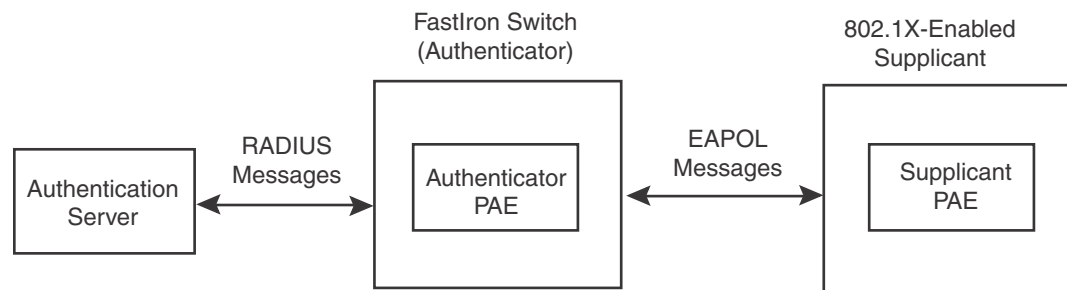

Authentication server – The device that validates the Client and specifies whether or not the Client may access services on the device. Brocade supports Authentication Servers running RADIUS.

Communication between the devices

For communication between the devices, 802.1X port security uses the **Extensible Authentication Protocol** (EAP), defined in RFC 2284. The 802.1X standard specifies a method for encapsulating EAP messages so that they can be carried over a LAN. This encapsulated form of EAP is known as EAP over LAN (**EAPOL**). The standard also specifies a means of transferring the EAPOL information between the Client/Supplicant, Authenticator, and Authentication Server.

EAPOL messages are passed between the **Port Access Entity (PAE)** on the Supplicant and the Authenticator. [Figure 189](#) shows the relationship between the Authenticator PAE and the Supplicant PAE.

FIGURE 189 Authenticator PAE and supplicant PAE

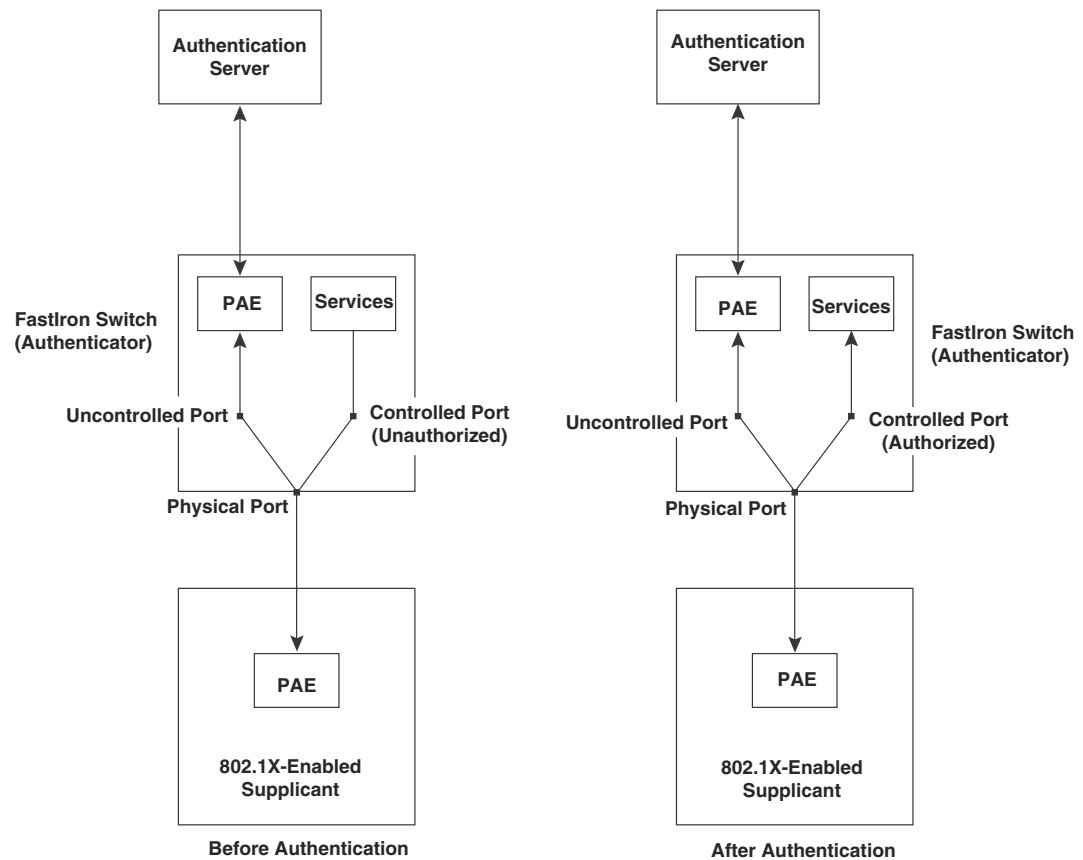

Authenticator PAE – The Authenticator PAE communicates with the Supplicant PAE, receiving identifying information from the Supplicant. Acting as a RADIUS client, the Authenticator PAE passes the Supplicant information to the Authentication Server, which decides whether the Supplicant can gain access to the port. If the Supplicant passes authentication, the Authenticator PAE grants it access to the port.

Supplicant PAE – The Supplicant PAE supplies information about the Client to the Authenticator PAE and responds to requests from the Authenticator PAE. The Supplicant PAE can also initiate the authentication procedure with the Authenticator PAE, as well as send log off messages.

Controlled and uncontrolled ports

A physical port on the device used with 802.1X port security has two virtual access points: a **controlled** port and an **uncontrolled** port. The controlled port provides full access to the network. The uncontrolled port provides access only for EAPOL traffic between the Client and the Authentication Server. When a Client is successfully authenticated, the controlled port is opened to the Client. [Figure 190](#) illustrates this concept.

FIGURE 190 Controlled and uncontrolled ports before and after client authentication

Before a Client is authenticated, only the uncontrolled port on the Authenticator is open. The uncontrolled port allows only EAPOL frames to be exchanged between the Client and the Authentication Server. The controlled port is in the unauthorized state and allows no traffic to pass through.

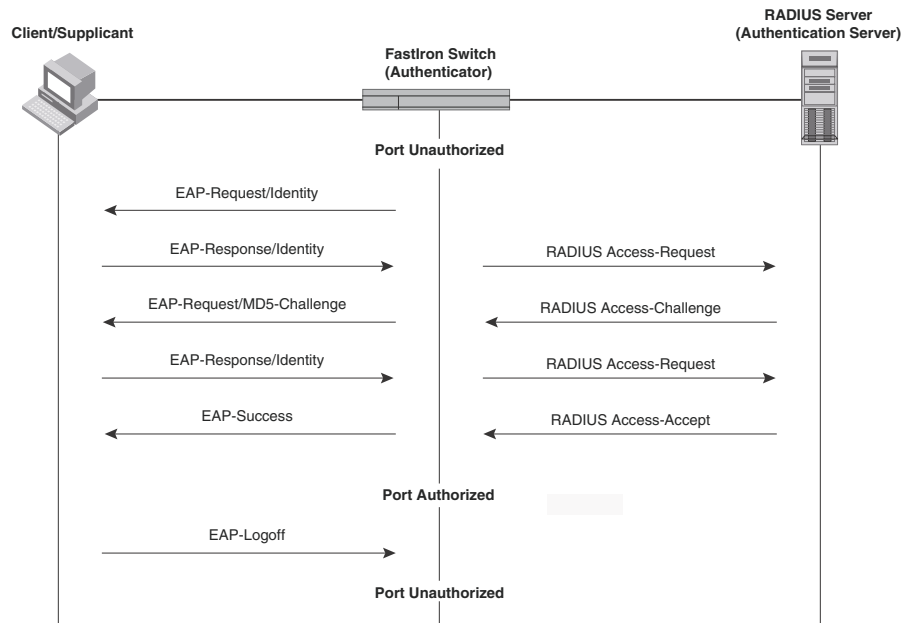

During authentication, EAPOL messages are exchanged between the Supplicant PAE and the Authenticator PAE, and RADIUS messages are exchanged between the Authenticator PAE and the Authentication Server. Refer to [“Message exchange during authentication”](#) on page 1793 for an example of this process. If the Client is successfully authenticated, the controlled port becomes authorized, and traffic from the Client can flow through the port normally.

By default, all controlled ports on the Brocade device are placed in the authorized state, allowing all traffic. When authentication is activated on an 802.1X-enabled interface, the interface controlled port is placed initially in the unauthorized state. When a Client connected to the port is successfully authenticated, the controlled port is then placed in the authorized state until the Client logs off. Refer to [“Enabling 802.1X port security”](#) on page 1810 for more information.

Message exchange during authentication

Figure 191 illustrates a sample exchange of messages between an 802.1X-enabled Client, a FastIron switch acting as Authenticator, and a RADIUS server acting as an Authentication Server.

FIGURE 191 Message exchange between client/supplicant, authenticator, and authentication server

In this example, the Authenticator (the FastIron switch) initiates communication with an 802.1X-enabled Client. When the Client responds, it is prompted for a username (255 characters maximum) and password. The Authenticator passes this information to the Authentication Server, which determines whether the Client can access services provided by the Authenticator. When the Client is successfully authenticated by the RADIUS server, the port is authorized. When the Client logs off, the port becomes unauthorized again.

The Brocade 802.1X implementation supports dynamic VLAN assignment. If one of the attributes in the Access-Accept message sent by the RADIUS server specifies a VLAN identifier, and this VLAN is available on the Brocade device, the client port is moved from its default VLAN to the specified VLAN. When the client disconnects from the network, the port is placed back in its default VLAN. Refer to [“Dynamic VLAN assignment for 802.1X port configuration”](#) on page 1802 for more information.

If a Client does not support 802.1X, authentication cannot take place. The Brocade device sends EAP-Request/Identity frames to the Client, but the Client does not respond to them.

When a Client that supports 802.1X attempts to gain access through a non-802.1X-enabled port, it sends an EAP start frame to the Brocade device. When the device does not respond, the Client considers the port to be authorized, and starts sending normal traffic.

Brocade devices support Identity and MD5-challenge requests in EAP Request/Response messages as well as the following 802.1X authentication challenge types:

NOTE

Refer to also [“EAP pass-through support”](#) on page 1795.

- **EAP-TLS (RFC 2716)** – EAP Transport Level Security (TLS) provides strong security by requiring both client and authentication server to be identified and validated through the use of public key infrastructure (PKI) digital certificates. EAP-TLS establishes a tunnel between the client and the authentication server to protect messages from unauthorized users' eavesdropping activities. Since EAP-TLS requires PKI digital certificates on both the clients and the authentication servers, the roll out, maintenance, and scalability of this authentication method is much more complex than other methods. EAP-TLS is best for installations with existing PKI certificate infrastructures.
- **EAP-TTLS (Internet-Draft)** – The EAP Tunnelled Transport Level Security (TTLS) is an extension of EAP-TLS. Like TLS, EAP-TTLS provides strong authentication; however it requires only the authentication server to be validated by the client through a certificate exchange between the server and the client. Clients are authenticated by the authentication server using user names and passwords.

A TLS tunnel can be used to protect EAP messages and existing user credential services such as Active Directory, RADIUS, and LDAP. Backward compatibility for other authentication protocols such as PAP, CHAP, MS-CHAP, and MS-CHAP-V2 are also provided by EAP-TTLS. EAP-TTLS is not considered foolproof and can be fooled into sending identity credentials if TLS tunnels are not used. EAP-TTLS is suited for installations that require strong authentication without the use of mutual PKI digital certificates.

- **PEAP (Internet-Draft)** – Protected EAP Protocol (PEAP) is an Internet-Draft that is similar to EAP-TTLS. PEAP client authenticates directly with the backend authentication server. The authenticator acts as a pass-through device, which does not need to understand the specific EAP authentication protocols.

Unlike EAP-TTLS, PEAP does not natively support user name and password to authenticate clients against an existing user database such as LDAP. PEAP secures the transmission between the client and authentication server with a TLS encrypted tunnel. PEAP also allows other EAP authentication protocols to be used. It relies on the mature TLS keying method for its key creation and exchange. PEAP is best suited for installations that require strong authentication without the use of mutual certificates.

Configuration for these challenge types is the same as for the EAP-MD5 challenge type.

NOTE

If the 802.1X Client will be sending a packet that is larger than 1500 bytes, you must enable **jumbo** at the Global config level of the CLI. If the supplicant or the RADIUS server does not support jumbo frames and jumbo is enabled on the switch, you can set the CPU IP MTU size. Refer to [“Setting the IP MTU size”](#), next.

Setting the IP MTU size

When jumbo frames are enabled on a FastIron device and the certificate in use is larger than the standard packet size of 1500 bytes, 802.1X authentication will not work if the supplicant or the RADIUS server does not support jumbo frames. In this case, you can change the IP MTU setting so that the certificate will be fragmented before it is forwarded to the supplicant or server for processing. This feature is supported in the Layer 2 switch code only. It is not supported in the Layer 3 router code.

To enable this feature, enter the following command at the Global CONFIG level of the CLI.

```
Brocade(config)# ip mtu 1500
```

Syntax: [no] ip mtu <num>

The <num> parameter specifies the MTU. Ethernet II packets can hold IP packets from 576 – 1500 bytes long. If jumbo mode is enabled, Ethernet II packets can hold IP packets from 576 – 10,222 bytes long. Ethernet SNAP packets can hold IP packets from 576 – 1492 bytes long. If jumbo mode is enabled, SNAP packets can hold IP packets from 576 to 10,214 bytes long. The default MTU is 1500 for Ethernet II packets and 1492 for SNAP packets.

EAP pass-through support

EAP pass-through is supported on FastIron devices that have 802.1X enabled. EAP pass-through support is fully compliant with RFC 3748, in which, by default, compliant pass-through authenticator implementations forward EAP challenge request packets of *any type*, including those listed in the previous section.

Configuration notes for setting the IP MTU size

If the 802.1X supplicant or authentication server will be sending packets that are greater than 1500 MTU, you should configure the device to accommodate a larger buffer size, in order to reduce problems during initial setup. Refer to [Chapter 26, “IP Configuration”](#).

Support for RADIUS user-name attribute in access-accept messages

Brocade 802.1X-enabled ports support the RADIUS user-name (type 1) attribute in the Access-Accept message returned during 802.1X authentication.

This feature is useful when the client/supplicant does not provide its user-name in the EAP-response/identity frame, and the username is key to providing useful information. For example, when the user-name attribute is sent in the Access-Accept message, it is then available for display in sFlow sample messages sent to a collector, and in the output of some show dot1x CLI commands, such as show dot1x mac-sessions.

This same information is sent as the “user-name” attribute of RADIUS accounting messages, and is sent to the RADIUS accounting servers.

To enable this feature, add the following attribute on the RADIUS server.

Attribute name	Type	Value
user-name	1	<name> (string)

Authenticating multiple hosts connected to the same port

Brocade devices support 802.1X authentication for ports with more than one host connected to them. [Figure 192](#) illustrates a sample configuration where multiple hosts are connected to a single 802.1X port.

FIGURE 192 Multiple hosts connected to a single 802.1X-enabled port

If there are multiple hosts connected to a single 802.1X-enabled port, the Brocade device authenticates each of them individually. Each host authentication status is independent of the others, so that if one authenticated host disconnects from the network, it has no effect on the authentication status of any of the other authenticated hosts.

By default, traffic from hosts that cannot be authenticated by the RADIUS server is dropped in hardware. You can optionally configure the Brocade device to assign the port to a “restricted” VLAN if authentication of the Client is unsuccessful.

How 802.1X multiple-host authentication works

When multiple hosts are connected to a single 802.1X-enabled port on a Brocade device (as in [Figure 192](#)), 802.1X authentication is performed in the following way.

1. One of the 802.1X-enabled Clients attempts to log into a network in which a Brocade device serves as an Authenticator.
2. The Brocade device creates an internal session (called a ***dot1x-mac-session***) for the Client. A dot1x-mac-session serves to associate a Client MAC address and username with its authentication status.
3. The Brocade device performs 802.1X authentication for the Client. Messages are exchanged between the Brocade device and the Client, and between the device and the Authentication Server (RADIUS server). The result of this process is that the Client is either successfully authenticated or not authenticated, based on the username and password supplied by the client.
4. If the Client is successfully authenticated, the Client dot1x-mac-session is set to “access-is-allowed”. This means that traffic from the Client can be forwarded normally.

5. If authentication for the Client is unsuccessful the first time, multiple attempts to authenticate the client will be made as determined by the **attempts** variable in the **auth-fail-max-attempts** command.
 - Refer to [“Specifying the number of authentication attempts the device makes before dropping packets”](#) on page 1816 for information on how to do this.
6. If authentication for the Client is unsuccessful more than the number of times specified by the attempts variable in the **auth-fail-max-attempts** command, an **authentication-failure** action is taken. The authentication-failure action can be either to drop traffic from the Client, or to place the port in a “restricted” VLAN:
 - If the authentication-failure action is to drop traffic from the Client, then the Client dot1x-mac-session is set to “access-denied”, causing traffic from the Client to be dropped in hardware.
 - If the authentication-failure action is to place the port in a “restricted” VLAN, If the Client dot1x-mac-session is set to “access-restricted” then the port is moved to the specified restricted VLAN, and traffic from the Client is forwarded normally.
7. When the Client disconnects from the network, the Brocade device deletes the Client dot1x-mac-session. This does not affect the dot1x-mac-session or authentication status (if any) of the other hosts connected on the port.

Configuration notes for 802.1x multiple-host authentication

- The Client dot1x-mac-session establishes a relationship between the username and MAC address used for authentication. If a user attempts to gain access from different Clients (with different MAC addresses), he or she would need to be authenticated from each Client.
- If a Client has been denied access to the network (that is, the Client dot1x-mac-session is set to “access-denied”), then you can cause the Client to be re-authenticated by manually disconnecting the Client from the network, or by using the **clear dot1x mac-session** command. Refer to [“Clearing a dot1x-mac-session for a MAC address”](#) on page 1817 for information on this command.
- When a Client has been denied access to the network, its dot1x-mac-session is aged out if no traffic is received from the Client MAC address over a fixed hardware aging period (70 seconds), plus a configurable software aging period. You can optionally change the software aging period for dot1x-mac-sessions or disable aging altogether. After the denied Client dot1x-mac-session is aged out, traffic from that Client is no longer blocked, and the Client can be re-authenticated.

In addition, you can configure disable aging for the dot1x-mac-session of Clients that have been granted either full access to the network, or have been placed in a restricted VLAN. After a Client dot1x-mac-session ages out, the Client must be re-authenticated. Refer to [“Disabling aging for dot1x-mac-sessions”](#) on page 1816 for more information.

- Dynamic IP ACL and MAC address filter assignment is supported in an 802.1X multiple-host configuration. Refer to [“Dynamically applying IP ACLs and MAC address filters to 802.1X ports”](#) on page 1806.
- 802.1X multiple-host authentication has the following additions:
 - Configurable hardware aging period for denied client dot1x-mac-sessions. Refer to [“Configurable hardware aging period for denied client dot1x-mac-sessions”](#) on page 1798.

- Dynamic ACL and MAC address filter assignment in 802.1X multiple-host configurations. Refer to [“Dynamically applying IP ACLs and MAC address filters to 802.1X ports”](#) on page 1806.
- Dynamic multiple VLAN assignment for 802.1X ports. Refer [“Dynamic multiple VLAN assignment for 802.1X ports”](#) on page 1803.
- Configure a restriction to forward authenticated and unauthenticated tagged and untagged clients to a restricted VLAN.
- Configure an override to send failed dot1x and non-dot1x clients to a restricted VLAN.
- Configure VLAN assignments for clients attempting to gain access through dual-mode ports.
- Enhancements to some **show** commands.
- Differences in command syntax for saving dynamic VLAN assignments to the startup-config file.

Configurable hardware aging period for denied client dot1x-mac-sessions

When one of the 802.1X-enabled Clients in a multiple-host configuration attempts to log into a network in which a Brocade device serves as an Authenticator, the device creates a dot1x-mac-session for the Client.

When a Client has been denied access to the network, its dot1x-mac-session is aged out if no traffic is received from the Client MAC address over a period of time. After a denied Client dot1x-mac-session ages out, the Client can be re-authenticated. Aging of a denied Client's dot1x-mac-session occurs in two phases, known as hardware aging and software aging.

The hardware aging period for a denied Client's dot1x-mac-session is not fixed at 70 seconds. The hardware aging period for a denied Client's dot1x-mac-session is equal to the length of time specified with the dot1x **timeout quiet-period** command. By default, the hardware aging time is 60 seconds. Once the hardware aging period ends, the software aging period begins. When the software aging period ends, the denied Client's dot1x-mac-session ages out, and the Client can be authenticated again.

802.1X port security and sFlow

sFlow is a standards-based protocol that allows network traffic to be sampled at a user-defined rate for the purpose of monitoring traffic flow patterns and identifying packet transfer rates on user-specified interfaces.

When you enable sFlow forwarding on an 802.1X-enabled interface, the samples taken from the interface include the user name string at the inbound or outbound port, or both, if that information is available.

For more information on sFlow, refer to [Chapter 15, “Network Monitoring”](#).

802.1X accounting

When 802.1X port security is enabled on the Brocade device, you can enable **802.1X accounting**. This feature enables the Brocade device to log information on the RADIUS server about authenticated 802.1X clients. The information logged on the RADIUS server includes the 802.1X client session ID, MAC address, and authenticating physical port number.

802.1X accounting works as follows.

1. A RADIUS server successfully authenticates an 802.1X client.
2. If 802.1X accounting is enabled, the Brocade device sends an 802.1X Accounting Start packet to the RADIUS server, indicating the start of a new session.
3. The RADIUS server acknowledges the Accounting Start packet.
4. The RADIUS server records information about the client.
5. When the session is concluded, the Brocade device sends an Accounting Stop packet to the RADIUS server, indicating the end of the session.
6. The RADIUS server acknowledges the Accounting Stop packet.

To enable 802.1X accounting, refer to [“802.1X accounting configuration”](#) on page 1818.

802.1X port security configuration

Configuring 802.1X port security on a Brocade device consists of the following tasks.

1. Configure the device interaction with the Authentication Server:
 - [“Configuring an authentication method list for 802.1X”](#) on page 1800
 - [“Setting RADIUS parameters”](#) on page 1800
 - [“Dynamic VLAN assignment for 802.1X port configuration”](#) on page 1802 (optional)
 - [“Dynamically applying IP ACLs and MAC address filters to 802.1X ports”](#) on page 1806
2. Configure the device role as the Authenticator:
 - [“Enabling 802.1X port security”](#) on page 1810
 - [“Initializing 802.1X on a port”](#) on page 1814 (optional)
3. Configure the device interaction with Clients:
 - [“Configuring periodic re-authentication”](#) on page 1811 (optional)
 - [“Re-authenticating a port manually”](#) on page 1812 (optional)
 - [“Setting the quiet period”](#) on page 1812 (optional)
 - [“Setting the wait interval for EAP frame retransmissions”](#) on page 1813 (optional)
 - [“Setting the maximum number of EAP frame retransmissions”](#) on page 1813 (optional)
 - [“Specifying a timeout for retransmission of messages to the authentication server”](#) on page 1814 (optional)
 - [“Allowing access to multiple hosts”](#) on page 1815 (optional)
 - [“MAC address filters for EAP frames”](#) on page 1817 (optional)

Configuring an authentication method list for 802.1X

To use 802.1X port security, you must specify an authentication method to be used to authenticate Clients. Brocade supports RADIUS authentication with 802.1X port security. To use RADIUS authentication with 802.1X port security, you create an authentication method list for 802.1X and specify RADIUS as an authentication method, then configure communication between the Brocade device and RADIUS server.

Example

```
Brocade(config)#aaa authentication dot1x default radius
```

Syntax: [no] **aaa authentication dot1x default** <method-list>

For the <method-list>, enter at least one of the following authentication methods

radius – Use the list of all RADIUS servers that support 802.1X for authentication.

none – Use no authentication. The Client is automatically authenticated by other means, without the device using information supplied by the Client.

NOTE

If you specify both **radius** and **none**, make sure **radius** comes before **none** in the method list.

Setting RADIUS parameters

To use a RADIUS server to authenticate access to a Brocade device, you must identify the server to the Brocade device.

Example

```
Brocade(config)#radius-server host 209.157.22.99 auth-port 1812 acct-port 1813
default key mirabeau dot1x
```

Syntax: **radius-server host** <ip-addr> | <ipv6-addr> | <server-name> [**auth-port** <num> | **acct-port** <num> | **default**] [**key** 0 | 1 <string>] [**dot1x**]

The **host** <ip-addr> | <ipv6-addr> | <server-name> parameter is either an IP address or an ASCII text string.

The **dot1x** parameter indicates that this RADIUS server supports the 802.1X standard. A RADIUS server that supports the 802.1X standard can also be used to authenticate non-802.1X authentication requests.

NOTE

To implement 802.1X port security, at least one of the RADIUS servers identified to the Brocade device must support the 802.1X standard.

Supported RADIUS attributes

Many IEEE 802.1X Authenticators will function as RADIUS clients. Some of the RADIUS attributes may be received as part of IEEE 802.1X authentication. Brocade devices support the following RADIUS attributes for IEEE 802.1X authentication:

- Username (1) – RFC 2865
- NAS-IP-Address (4) – RFC 2865
- NAS-Port (5) – RFC 2865

- Service-Type (6) – RFC 2865
- FilterId (11) – RFC 2865
- Framed-MTU (12) – RFC 2865
- State (24) – RFC 2865
- Vendor-Specific (26) – RFC 2865
- Session-Timeout (27) – RFC 2865
- Termination-Action (29) – RFC 2865
- Calling-Station-ID (31) – RFC 2865
- NAS-Port-Type (61) – RFC 2865
- Tunnel-Type (64) – RFC 2868
- Tunnel-Medium-Type (65) – RFC 2868
- EAP Message (79) – RFC 2579
- Message-Authenticator (80) RFC 3579
- Tunnel-Private-Group-Id (81) – RFC 2868
- NAS-Port-id (87) – RFC 2869

Specifying the RADIUS timeout action

A RADIUS timeout occurs when the Brocade device does not receive a response from a RADIUS server within a specified time limit and after a certain number of retries. The time limit and number of retries can be manually configured using the CLI commands **radius-server timeout** and **radius-server retransmit**, respectively. If the parameters are not manually configured, the Brocade device applies the default value of three seconds time limit with a maximum of three retries.

You can better control port behavior when a RADIUS timeout occurs. That is, you can configure a port on the Brocade device to automatically pass or fail users being authenticated. A **pass** essentially bypasses the authentication process and permits user access to the network. A **fail** bypasses the authentication process and blocks user access to the network, unless restrict-vlan is configured, in which case, the user is placed into a VLAN with restricted or limited access. By default, the Brocade device will reset the authentication process and retry to authenticate the user.

Specify the RADIUS timeout action at the Interface level of the CLI.

Permit user access to the network after a RADIUS timeout

To set the RADIUS timeout behavior to bypass 802.1X authentication and *permit* user access to the network, enter commands such as the following

```
Brocade(config)#interface ethernet 3/1
Brocade(config-if-e100-3/1)#dot1x auth-timeout-action success
```

Syntax: [no] dot1x auth-timeout-action success

Once the *success* timeout action is enabled, use the **no** form of the command to reset the RADIUS timeout behavior to *retry*.

Re-authenticate a user

To configure RADIUS timeout behavior to bypass multi-device port authentication and *permit* user access to the network, enter commands similar to the following

```
Brocade(config)#interface ethernet 3/1
Brocade(config-if-e100-3/1)#dot1x re-auth-timeout-success 60
```

Syntax: [no] **dot1x re-auth-timeout-success** <seconds>

The <seconds> parameter specifies the number of seconds the device will wait to re-authenticate a user after a timeout. The minimum value is 10 seconds. The maximum value is $2^{16}-1$ (maximum unsigned 16-bit value).

Deny user access to the network after a RADIUS timeout

To set the RADIUS timeout behavior to bypass 802.1X authentication and *block* user access to the network, enter commands such as the following

```
Brocade(config)#interface ethernet 3/1
Brocade(config-if-e100-3/1)#dot1x auth-timeout-action failure
```

Syntax: [no] **dot1x auth-timeout-action failure**

Once the failure timeout action is enabled, use the **no** form of the command to reset the RADIUS timeout behavior to **retry**.

NOTE

If **restrict-vlan** is configured along with **auth-timeout-action failure**, the user will be placed into a VLAN with restricted or limited access. Refer to [“Allow user access to a restricted VLAN after a RADIUS timeout”](#) on page 1802.

Allow user access to a restricted VLAN after a RADIUS timeout

To set the RADIUS timeout behavior to bypass 802.1X authentication and place the user in a VLAN with restricted or limited access, enter commands such as the following

```
Brocade(config)#interface ethernet 3/1
Brocade(config-if-e100-3/1)#dot1x auth-timeout-action failure
```

Syntax: [no] **dot1x auth-timeout-action failure**

NOTE

The commands **auth-fail-action restrict-vlan** and **auth-fail-vlanid** are supported in the global dot1x mode and are not supported at the port-level. The failure action of **dot1x auth-timeout-action failure** will follow the **auth-fail-action** defined at the global dot1x level.

Dynamic VLAN assignment for 802.1X port configuration

When a client successfully completes the EAP authentication process, the Authentication Server (the RADIUS server) sends the Authenticator (the Brocade device) a RADIUS Access-Accept message that grants the client access to the network. The RADIUS Access-Accept message contains attributes set for the user in the user's access profile on the RADIUS server.

If one of the attributes in the Access-Accept message specifies a VLAN identifier, and if this VLAN is available on the Brocade device, the client port is moved from its default VLAN to this specified VLAN.

NOTE

This feature is supported on port-based VLANs only. This feature cannot be used to place an 802.1X-enabled port into a Layer 3 protocol VLAN.

Automatic removal of dynamic VLAN assignments for 802.1X ports

For increased security, this feature removes any association between a port and a dynamically-assigned VLAN when all 802.1x sessions for that VLAN have expired on the port.

NOTE

When a **show run** command is issued during a session, the dynamically-assigned VLAN is not displayed.

Enable 802.1X VLAN ID support by adding the following attributes to a user profile on the RADIUS server.

Attribute name	Type	Value
Tunnel-Type	064	13 (decimal) – VLAN
Tunnel-Medium-Type	065	6 (decimal) – 802
Tunnel-Private-Group-ID	081	<vlan-name> (string) – either the name or the number of a VLAN configured on the Brocade device.

The device reads the attributes as follows:

- If the Tunnel-Type or the Tunnel-Medium-Type attributes in the Access-Accept message do not have the values specified above, the Brocade device ignores the three Attribute-Value pairs. The client becomes authorized, but the client port is not dynamically placed in a VLAN.
- If the Tunnel-Type or the Tunnel-Medium-Type attributes in the Access-Accept message do have the values specified above, but there is no value specified for the Tunnel-Private-Group-ID attribute, the client will not become authorized.
- When the Brocade device receives the value specified for the Tunnel-Private-Group-ID attribute, it checks whether the <vlan-name> string matches the name of a VLAN configured on the device. If there is a VLAN on the device whose name matches the <vlan-name> string, then the client port is placed in the VLAN whose ID corresponds to the VLAN name.
- If the <vlan-name> string does not match the name of a VLAN, the Brocade device checks whether the string, when converted to a number, matches the ID of a VLAN configured on the device. If it does, then the client port is placed in the VLAN with that ID.
- If the <vlan-name> string does not match either the name or the ID of a VLAN configured on the device, then the client will not become authorized.

The **show interface** command displays the VLAN to which an 802.1X-enabled port has been dynamically assigned, as well as the port from which it was moved (that is, the port default VLAN). Refer to [“Displaying dynamically-assigned VLAN information”](#) on page 1825 for sample output indicating the port dynamically assigned VLAN.

Dynamic multiple VLAN assignment for 802.1X ports

When you add attributes to a user profile on the RADIUS server, the <vlan-name> value for the Tunnel-Private-Group-ID attribute can specify the name or number of one or more VLANs configured on the Brocade device.

For example, to specify one VLAN, configure the following for the `<vlan-name>` value in the Tunnel-Private-Group-ID attribute on the RADIUS server.

"10" or "marketing"

In this example, the port on which the Client is authenticated is assigned to VLAN 10 or the VLAN named "marketing". The VLAN to which the port is assigned must have previously been configured on the Brocade device.

Specifying an untagged VLAN

To specify an untagged VLAN, use the following.

"U:10" or "U:marketing"

When the RADIUS server specifies an untagged VLAN ID, the port default VLAN ID (or **PVID**) is changed from the system DEFAULT-VLAN (VLAN 1) to the specified VLAN ID. The port transmits only untagged traffic on its PVID. In this example, the port PVID is changed from VLAN 1 (the DEFAULT-VLAN) to VLAN 10 or the VLAN named "marketing".

The PVID for a port can be changed only once through RADIUS authentication. For example, if RADIUS authentication for a Client causes a port PVID to be changed from 1 to 10, and then RADIUS authentication for another Client on the same port specifies that the port PVID be moved to 20, then the second PVID assignment from the RADIUS server is ignored.

If the link goes down, or the dot1x-mac-session for the Client that caused the initial PVID assignment ages out, then the port reverts back to its original (non-RADIUS-specified) PVID, and subsequent RADIUS authentication can change the PVID assignment for the port.

If a port PVID is assigned through the multi-device port authentication feature, and 802.1X authentication subsequently specifies a different PVID, then the PVID specified through 802.1X authentication overrides the PVID specified through multi-device port authentication.

Specifying a tagged VLAN

To specify a tagged VLAN, use the following.

"T:12;T:20" or "T:12;T:marketing"

In this example, the port is added to VLANs 12 and 20 or VLANs 12 and the VLAN named "marketing". When a tagged packet is authenticated, and a list of VLANs is specified on the RADIUS server for the MAC address, then the packet tag must match one of the VLANs in the list in order for the Client to be successfully authenticated. If authentication is successful, then the port is added to all of the VLANs specified in the list.

Unlike with a RADIUS-specified untagged VLAN, if the dot1x-mac-session for the Client ages out, the port membership in RADIUS-specified tagged VLANs is not changed. In addition, if multi-device port authentication specifies a different list of tagged VLANs, then the port is added to the specified list of VLANs. Membership in the VLANs specified through 802.1X authentication is not changed.

Specifying an untagged VLAN and multiple tagged VLANs

To specify an untagged VLAN and multiple tagged VLANs, use the following.

"U:10;T:12;T:marketing"

When the RADIUS server returns a value specifying both untagged and tagged VLAN IDs, the port becomes a dual-mode port, accepting and transmitting both tagged traffic and untagged traffic at the same time. A dual-mode port transmits only untagged traffic on its default VLAN (PVID) and only tagged traffic on all other VLANs.

In this example, the port VLAN configuration is changed so that it transmits untagged traffic on VLAN 10, and transmits tagged traffic on VLAN 12 and the VLAN named "marketing".

For a configuration example, refer to [“802.1X Authentication with dynamic VLAN assignment”](#) on page 1835.

Saving dynamic VLAN assignments to the running-config file

You can configure the Brocade device to save the RADIUS-specified VLAN assignments to the device's running-config file. Enter commands such as the following.

```
Brocade(config)#dot1x-enable
Brocade(config-dot1x)#save-dynamicvlan-to-config
```

Syntax: save-dynamicvlan-to-config

By default, the dynamic VLAN assignments are not saved to the running-config file. Entering the **show running-config** command does not display dynamic VLAN assignments, although they can be displayed with the **show vlan** and **show authenticated-mac-address detail** commands.

NOTE

When this feature is enabled, issuing the command **write mem** will save any dynamic VLAN assignments to the startup configuration file.

Considerations for dynamic VLAN assignment in an 802.1X multiple-host configuration

The following considerations apply when a Client in a 802.1X multiple-host configuration is successfully authenticated, and the RADIUS Access-Accept message specifies a VLAN for the port:

- If the port is not already a member of a RADIUS-specified VLAN, and the RADIUS Access-Accept message specifies the name or ID of a valid VLAN on the Brocade device, then the port is placed in that VLAN.
- If the port is already a member of a RADIUS-specified VLAN, and the RADIUS Access-Accept message specifies the name or ID of a different VLAN, then it is considered an authentication failure. The port VLAN membership is not changed.
- If the port is already a member of a RADIUS-specified VLAN, and the RADIUS Access-Accept message specifies the name or ID of that same VLAN, then traffic from the Client is forwarded normally.
- If the RADIUS Access-Accept message specifies the name or ID of a VLAN that does not exist on the Brocade device, then it is considered an authentication failure.
- If the port is a tagged or dual-mode port, and the RADIUS Access-Accept message specifies the name or ID of a valid VLAN on the Brocade device, then the port is placed in that VLAN. If the port is already a member of the RADIUS-specified VLAN, no further action is taken.
- If the RADIUS Access-Accept message does not contain any VLAN information, the Client dot1x-mac-session is set to “access-is-allowed”. If the port is already in a RADIUS-specified VLAN, it remains in that VLAN.

Dynamically applying IP ACLs and MAC address filters to 802.1X ports

The Brocade 802.1X implementation supports dynamically applying an IP ACL or MAC address filter to a port, based on information received from an Authentication Server.

When a client/supplicant successfully completes the EAP authentication process, the Authentication Server (the RADIUS server) sends the Authenticator (the Brocade device) a RADIUS Access-Accept message that grants the client access to the network. The RADIUS Access-Accept message contains attributes set for the user in the user's access profile on the RADIUS server.

If the Access-Accept message contains Filter-ID (type 11) or Vendor-Specific (type 26), or both attributes, the Brocade device can use information in these attributes to apply an IP ACL or MAC address filter to the authenticated port. This IP ACL or MAC address filter applies to the port for as long as the client is connected to the network. When the client disconnects from the network, the IP ACL or MAC address filter is no longer applied to the port. If an IP ACL or MAC address filter had been applied to the port prior to 802.1X authentication, it is then re-applied to the port.

The Brocade device uses information in the Filter ID and Vendor-Specific attributes as follows:

- The Filter-ID attribute can specify the number of an existing IP ACL or MAC address filter configured on the Brocade device. In this case, the IP ACL or MAC address filter with the specified number is applied to the port.
- The Vendor-Specific attribute can specify actual syntax for a Brocade IP ACL or MAC address filter, which is then applied to the authenticated port. Configuring a Vendor-Specific attribute in this way allows you to create IP ACLs and MAC address filters that apply to individual users; that is, *per-user* IP ACLs or MAC address filters.

Configuration considerations for applying IP ACLs and MAC address filters to 802.1x ports

The following restrictions apply to dynamic IP ACLs or MAC address filters:

- Inbound dynamic IP ACLs are supported. Outbound dynamic ACLs are not supported.
- Inbound Vendor-Specific attributes are supported. Outbound Vendor-Specific attributes are not supported.
- A maximum of one IP ACL can be configured in the inbound direction on an interface.
- 802.1X with dynamic MAC filter will work for one client at a time on a port. If a second client tries to authenticate with 802.1X and dynamic MAC filter, the second client will be rejected.
- MAC address filters cannot be configured in the outbound direction on an interface.
- Concurrent operation of MAC address filters and IP ACLs is not supported.
- A dynamic IP ACL will take precedence over an IP ACL that is bound to a port (port ACL). When a client authenticates with a dynamic IP ACL, the port ACL will not be applied. Also, future clients on the same port will authenticate with a dynamic IP ACL or no IP ACL. If no clients on the port use dynamic ACL, then the port ACL will be applied to all traffic.

Disabling and enabling strict security mode for dynamic filter assignment

By default, 802.1X dynamic filter assignment operates in **strict security mode**. When strict security mode is enabled, 802.1X authentication for a port fails if the Filter-ID attribute contains invalid information, or if insufficient system resources are available to implement the per-user IP ACLs or MAC address filters specified in the Vendor-Specific attribute.

When strict security mode is enabled:

- If the Filter-ID attribute in the Access-Accept message contains a value that does not refer to an existing filter (that is, a MAC address filter or IP ACL configured on the device), then the port will not be authenticated, regardless of any other information in the message (for example, if the Tunnel-Private-Group-ID attribute specifies a VLAN on which to assign the port).
- If the Vendor-Specific attribute specifies the syntax for a filter, but there are insufficient system resources to implement the filter, then the port will not be authenticated.
- If the device does not have the system resources available to dynamically apply a filter to a port, then the port will not be authenticated.

NOTE

If the Access-Accept message contains values for both the Filter-ID and Vendor-Specific attributes, then the value in the Vendor-Specific attribute (the per-user filter) takes precedence.

Also, if authentication for a port fails because the Filter-ID attribute referred to a non-existent filter, or there were insufficient system resources to implement the filter, then a Syslog message is generated.

Disabled strict security mode

When strict security mode is disabled:

- If the Filter-ID attribute in the Access-Accept message contains a value that does not refer to an existing filter (that is, a MAC address filter or IP ACL configured on the device), then the port is still authenticated, but no filter is dynamically applied to it.
- If the Vendor-Specific attribute specifies the syntax for a filter, but there are insufficient system resources to implement the filter, then the port is still authenticated, but the filter specified in the Vendor-Specific attribute is not applied to the port.

By default, strict security mode is enabled for all 802.1X-enabled interfaces, but you can manually disable or enable it, either globally or for specific interfaces.

Disabling strict security mode globally

To disable strict security mode globally, enter the following commands.

```
Brocade(config)#dot1x-enable
Brocade(config-dot1x)#no global-filter-strict-security
```

After you globally disable strict security mode, you can re-enable it by entering the following command.

```
Brocade(config-dot1x)#global-filter-strict-security
```

Syntax: [no] global-filter-strict-security

To disable strict security mode for a specific interface, enter commands such as the following.

```
Brocade(config)#interface e 1
Brocade(config-if-e1000-1)#dot1x disable-filter-strict-security
```

To re-enable strict security mode for an interface, enter the following command.

```
Brocade(config-if-e1000-1)#no dot1x disable-filter-strict-security
```

Syntax: [no] dot1x disable-filter-strict-security

The output of the **show dot1x** and **show dot1x config** commands has been enhanced to indicate whether strict security mode is enabled or disabled globally and on an interface. Refer to [“Displaying the status of strict security mode”](#) on page 1828.

Dynamically applying existing ACLs or MAC address filters

When a port is authenticated using 802.1X security, an IP ACL or MAC address filter that exists in the running-config on the Brocade device can be dynamically applied to the port. To do this, you configure the Filter-ID (type 11) attribute on the RADIUS server. The Filter-ID attribute specifies the name or number of the Brocade IP ACL or MAC address filter.

The following is the syntax for configuring the Filter-ID attribute to refer to a Brocade IP ACL or MAC address filter.

Value	Description
ip.<number>.in	Applies the specified numbered ACL to the 802.1X authenticated port in the inbound direction.
ip.<name>.in	Applies the specified named ACL to the 802.1X authenticated port in the inbound direction.
mac.<number>.in	Applies the specified numbered MAC address filter to the 802.1X authenticated port in the inbound direction.

The following table lists examples of values you can assign to the Filter-ID attribute on the RADIUS server to refer to IP ACLs and MAC address filters configured on a Brocade device.

Possible values for the filter ID attribute on the RADIUS server	ACL or MAC address filter configured on the Brocade device
ip.2.in	access-list 2 permit host 36.48.0.3 access-list 2 permit 36.0.0.0 0.255.255.255
ip.102.in	access-list 102 permit ip 36.0.0.0 0.255.255.255 any
ip.fdry_filter.in	ip access-list standard fdry_filter permit host 36.48.0.3
mac.2.in	mac filter 2 permit 3333.3333.3333 ffff.ffff.ffff any etype eq 0800
mac.2.in	mac filter 2 permit 3333.3333.3333 ffff.ffff.ffff any etype eq 0800
mac.3.in	mac filter 3 permit 2222.2222.2222 ffff.ffff.ffff any etype eq 0800

Notes for dynamically applying ACLs or MAC address filters

- The <name> in the Filter ID attribute is case-sensitive.
- You can specify only numbered MAC address filters in the Filter ID attribute. Named MAC address filters are not supported.
- Dynamic ACL filters are supported only for the inbound direction. Dynamic outbound ACL filters are not supported.
- MAC address filters are supported only for the inbound direction. Outbound MAC address filters are not supported.
- Dynamically assigned IP ACLs and MAC address filters are subject to the same configuration restrictions as non-dynamically assigned IP ACLs and MAC address filters.

Configuring per-user IP ACLs or MAC address filters

Per-user IP ACLs and MAC address filters make use of the Vendor-Specific (type 26) attribute to dynamically apply filters to ports. Defined in the Vendor-Specific attribute are Brocade ACL or MAC address filter statements. When the RADIUS server returns the Access-Accept message granting a client access to the network, the Brocade device reads the statements in the Vendor-Specific attribute and applies these IP ACLs or MAC address filters to the client port. When the client disconnects from the network, the dynamically applied filters are no longer applied to the port. If any filters had been applied to the port previous to the client connecting, then those filters are reapplied to the port.

NOTE

Dynamic IP ACL filters and MAC address filters are not supported on the same port at the same time.

The following table shows the syntax for configuring the Brocade Vendor-Specific attributes with ACL or MAC address filter statements.

Value	Description
ipACL.e.in=<extended-ACL-entries>	Applies the specified extended ACL entries to the 802.1X authenticated port in the inbound direction.
macfilter.in=<mac-filter-entries>	Applies the specified MAC address filter entries to the 802.1X authenticated port in the inbound direction.

The following table shows examples of IP ACLs and MAC address filters configured in the Brocade Vendor-Specific attribute on a RADIUS server. These IP ACLs and MAC address filters follow the same syntax as other Brocade ACLs and MAC address filters. Refer to the related chapters in this book for information on syntax.

ACL or MAC address filter	Vendor-specific attribute on RADIUS server
MAC address filter with one entry	macfilter.in= deny any any
MAC address filter with two entries	macfilter.in= permit 0000.0000.3333 ffff.ffff.0000 any, macfilter.in= permit 0000.0000.4444 ffff.ffff.0000 any

The RADIUS server allows one instance of the Vendor-Specific attribute to be sent in an Access-Accept message.

Enabling 802.1X port security

By default, 802.1X port security is disabled on Brocade devices. To enable the feature on the device and enter the dot1x configuration level, enter the following command.

```
Brocade(config)#dot1x-enable
Brocade(config-dot1x)#
```

Syntax: [no] dot1x-enable

At the dot1x configuration level, you can enable 802.1X port security on all interfaces at once, on individual interfaces, or on a range of interfaces.

For example, to enable 802.1X port security on all interfaces on the device, enter the following command.

```
Brocade(config-dot1x)#enable all
```

Syntax: [no] enable all

To enable 802.1X port security on interface 3/11, enter the following command.

```
Brocade(config-dot1x)#enable ethernet 3/11
```

Syntax: [no] enable ethernet <port>

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

To enable 802.1X port security on interfaces 3/11 through 3/16, enter the following command.

```
Brocade(config-dot1x)#enable ethernet 3/11 to 3/16
```

Syntax: [no] enable ethernet <port> to <port>

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Setting the port control

To activate authentication on an 802.1X-enabled interface, you specify the kind of **port control** to be used on the interface. An interface used with 802.1X port security has two virtual access points: a controlled port and an uncontrolled port:

- The controlled port can be either the authorized or unauthorized state. In the authorized state, it allows normal traffic to pass between the Client and the Authenticator. In the unauthorized state, no traffic is allowed to pass.
- The uncontrolled port allows only EAPOL traffic between the Client and the Authentication Server.

Refer to [Figure 190](#) for an illustration of this concept.

By default, all controlled ports on the device are in the authorized state, allowing all traffic. When you activate authentication on an 802.1X-enabled interface, its controlled port is placed in the unauthorized state. When a Client connected to the interface is successfully authenticated, the controlled port is then placed in the authorized state. The controlled port remains in the authorized state until the Client logs off.

To activate authentication on an 802.1X-enabled interface, you configure the interface to place its controlled port in the authorized state when a Client is authenticated by an Authentication Server. To do this, enter commands such as the following.

```
Brocade(config)#interface e 3/1
Brocade(config-if-3/1)#dot1x port-control auto
```

Syntax: [no] dot1x port-control [force-authorized | force-unauthorized | auto]

When an interface control type is set to **auto**, the controlled port is initially set to unauthorized, but is changed to authorized when the connecting Client is successfully authenticated by an Authentication Server.

The port control type can be one of the following

force-authorized – The controlled port is placed unconditionally in the authorized state, allowing all traffic. This is the default state for ports on the Brocade device.

force-unauthorized – The controlled port is placed unconditionally in the unauthorized state.

auto – The controlled port is unauthorized until authentication takes place between the Client and Authentication Server. Once the Client passes authentication, the port becomes authorized. This activates authentication on an 802.1X-enabled interface.

NOTE

You cannot enable 802.1X port security on ports that have any of the following features enabled:

- Link aggregation
- Metro Ring Protocol (MRP)
- Mirror port
- Trunk port

Configuring periodic re-authentication

You can configure the device to periodically re-authenticate Clients connected to 802.1X-enabled interfaces. When you enable periodic re-authentication, the device re-authenticates Clients every 3,600 seconds by default. You can optionally specify a different re-authentication interval of between 1 – 4294967295 seconds.

To configure periodic re-authentication using the default interval of 3,600 seconds, enter the following command.

```
Brocade(config-dot1x)#re-authentication
```

Syntax: [no] re-authentication

To configure periodic re-authentication with an interval of 2,000 seconds, enter the following commands.

```
Brocade(config-dot1x)#re-authentication
Brocade(config-dot1x)#timeout re-authperiod 2000
```

Syntax: `[no] timeout re-authperiod <seconds>`

The re-authentication interval is a global setting, applicable to all 802.1X-enabled interfaces. To re-authenticate Clients connected to a specific port manually, use the **dot1x re-authenticate** command. Refer to [“Re-authenticating a port manually”](#), below.

Re-authenticating a port manually

When periodic re-authentication is enabled, by default the Brocade device re-authenticates Clients connected to an 802.1X-enabled interface every 3,600 seconds (or the time specified by the **dot1x timeout re-authperiod** command). You can also manually re-authenticate Clients connected to a specific port.

For example, to re-authenticate Clients connected to interface 3/1, enter the following command.

```
Brocade#dot1x re-authenticate e 3/1
```

Syntax: `dot1x re-authenticate ethernet <port>`

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Setting the quiet period

If the Brocade device is unable to authenticate the Client, the Brocade device waits a specified amount of time before trying again. The amount of time the Brocade device waits is specified with the **quiet-period** parameter. The **quiet-period** parameter can be from 1 – 4294967295 seconds. The default is 60 seconds.

For example, to set the quiet period to 30 seconds, enter the following command.

```
Brocade(config-dot1x)#timeout quiet-period 30
```

Syntax: `[no] timeout quiet-period <seconds>`

Specifying the wait interval and number of EAP-request/identity frame retransmissions from the Brocade device

When the Brocade device sends an EAP-request/identity frame to a Client, it expects to receive an EAP-response/identity frame from the Client. By default, if the Brocade device does not receive an EAP-response/identity frame from a Client, the device waits 30 seconds, then retransmits the EAP-request/identity frame. Also by default, the Brocade device retransmits the EAP-request/identity frame a maximum of two times. You can optionally configure the amount of time the device will wait before retransmitting an EAP-request/identity frame, and the number of times the EAP-request/identity frame will be transmitted. This section provides the command syntax for these features.

Setting the wait interval for EAP frame retransmissions

By default, if the Brocade device does not receive an EAP-response/identity frame from a Client, the device waits 30 seconds, then retransmits the EAP-request/identity frame. You can optionally change the amount of time the Brocade device waits before retransmitting the EAP-request/identity frame to the Client.

For example, to cause the Brocade device to wait 60 seconds before retransmitting an EAP-request/identity frame to a Client, enter the following command.

```
Brocade(config-dot1x)#timeout tx-period 60
```

If the Client does not send back an EAP-response/identity frame within 60 seconds, the device will transmit another EAP-request/identity frame.

Syntax: [no] timeout tx-period <seconds>

where <seconds> is a value from 1 – 4294967295. The default is 30 seconds.

Setting the maximum number of EAP frame retransmissions

The Brocade device retransmits the EAP-request/identity frame a maximum of two times. If no EAP-response/identity frame is received from the Client after two EAP-request/identity frame retransmissions (or the amount of time specified with the **auth-max** command), the device restarts the authentication process with the Client.

You can optionally change the number of times the Brocade device should retransmit the EAP-request/identity frame. You can specify between 1 – 10 frame retransmissions. For example, to configure the device to retransmit an EAP-request/identity frame to a Client a maximum of three times, enter the following command:

```
Brocade(config-dot1x)#auth-max 3
```

Syntax: auth-max <value>

<value> is a number from 1 – 10. The default is 2.

Wait interval and number of EAP-request/identity frame retransmissions from the RADIUS server

Acting as an intermediary between the RADIUS Authentication Server and the Client, the Brocade device receives RADIUS messages from the RADIUS server, encapsulates them as EAPOL frames, and sends them to the Client. By default, when the Brocade device relays an EAP-Request frame from the RADIUS server to the Client, it expects to receive a response from the Client within 30 seconds. If the Client does not respond within the allotted time, the device retransmits the EAP-Request frame to the Client. Also by default, the Brocade device retransmits the EAP-request frame twice. If no EAP-response frame is received from the Client after two EAP-request frame retransmissions, the device restarts the authentication process with the Client.

You can optionally configure the amount of time the device will wait before retransmitting an EAP-request/identity frame, and the number of times the EAP-request/identity frame will be transmitted. This section provides the command syntax for these features.

Setting the wait interval for EAP frame retransmissions

By default, when the Brocade device relays an EAP-Request frame from the RADIUS server to the Client, it expects to receive a response from the Client within 30 seconds. You can optionally specify the wait interval using the **supptimeout** command.

For example, to configure the device to retransmit an EAP-Request frame if the Client does not respond within 45 seconds, enter the following command.

```
Brocade(config-dot1x)#supptimeout 45
```

Syntax: **supptimeout** <seconds>

<seconds> is a number from 1 – 4294967295 seconds. The default is 30 seconds.

Setting the maximum number of EAP frame retransmissions

You can optionally specify the number of times the Brocade device will retransmit the EAP-request frame. You can specify between 1 – 10 frame retransmissions. For example, to configure the device to retransmit an EAP-request frame to a Client a maximum of three times, enter the following command.

```
Brocade(config-dot1x)#maxreq 3
```

Syntax: **maxreq** <value>

<value> is a number from 1 – 10. The default is 2.

Specifying a timeout for retransmission of messages to the authentication server

When performing authentication, the Brocade device receives EAPOL frames from the Client and passes the messages on to the RADIUS server. The device expects a response from the RADIUS server within 30 seconds. If the RADIUS server does not send a response within 30 seconds, the Brocade device retransmits the message to the RADIUS server. The time constraint for retransmission of messages to the Authentication Server can be between 0 – 4294967295 seconds.

For example, to configure the device to retransmit a message if the Authentication Server does not respond within 45 seconds, enter the following command.

```
Brocade(config-dot1x)#servertimeout 45
```

Syntax: **servertimeout** <seconds>

Initializing 802.1X on a port

To initialize 802.1X port security on a port, enter a command such as the following.

```
Brocade#dot1x initialize e 3/1
```

Syntax: **dot1x initialize ethernet** <port>

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*

- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Allowing access to multiple hosts

Brocade devices support 802.1X authentication for ports with more than one host connected to them. If there are multiple hosts connected to a single 802.1X-enabled port, the Brocade device authenticates each of them individually. Refer to [“Configuring 802.1X multiple-host authentication”](#) on page 1815.

Configuring 802.1X multiple-host authentication

When multiple hosts are connected to the same 802.1X-enabled port, the functionality described in [“How 802.1X multiple-host authentication works”](#) on page 1796 is enabled by default. You can optionally do the following:

- Specify the authentication-failure action
- Specify the number of authentication attempts the device makes before dropping packets
- Disabling aging for dot1x-mac-sessions
- Configure aging time for blocked clients
- Moving native VLAN mac-sessions to restrict VLAN
- Clear the dot1x-mac-session for a MAC address

Specifying the authentication-failure action

In an 802.1X multiple-host configuration, if RADIUS authentication for a client is unsuccessful, either traffic from that client is dropped in hardware (the default), or the client port is placed in a “restricted” VLAN. You can specify which of these authentication-failure actions to use. When you enable 802.1X, the default authentication-failure action is to drop client traffic.

If you configure the authentication-failure action to place the client port in a restricted VLAN, you can specify the ID of the restricted VLAN. If you do not specify a VLAN ID, the default VLAN is used.

You can configure the authentication-failure action using one of the following methods:

- Configure the same authentication-failure action for all ports on the device (globally).
- Configure an authentication-failure action on individual ports.

NOTE

You cannot configure the authentication-failure action globally and per-port at the same time.

To configure the authentication-failure action for all ports on the device to place the client port in a restricted VLAN, enter the following commands.

```
Brocade(config)# dot1x-enable
Brocade(config-dot1x)#auth-fail-action restricted-vlan
```

Syntax: [no] auth-fail-action restricted-vlan

To specify VLAN 300 as the restricted VLAN for all ports on the device, enter the **auth-fail-vlanid** *<num>* command.

```
Brocade(config-dot1x)# auth-fail-vlanid 300
```

Syntax: [no] auth-fail-vlanid *<vlan-id>*

To specify on an individual port that the authentication-failure action is to place the client port in restricted VLAN 300, enter the following command at the interface configuration level.

```
Brocade(config-if-e1000-1/1/1)# dot1x auth-fail-action restrict-vlan 300
```

Syntax: [no] dot1x auth-fail-action restrict-vlan <vlan-id>

Specifying the number of authentication attempts the device makes before dropping packets

When the authentication-failure action is to drop traffic from the Client, and the initial authentication attempt made by the device to authenticate the Client is unsuccessful, the Brocade device immediately retries to authenticate the Client. After three unsuccessful authentication attempts, the Client dot1x-mac-session is set to “access-denied”, causing traffic from the Client to be dropped in hardware.

Optionally, you can configure the number of authentication attempts the device makes before dropping traffic from the Client. To do so, enter a command such as the following.

```
Brocade(config-dot1x)# auth-fail-max-attempts 2
```

Syntax: [no] auth-fail-max-attempts <attempts>

By default, the device makes three attempts to authenticate a Client before dropping packets from the Client. You can specify from 1 through 10 authentication attempts.

Disabling aging for dot1x-mac-sessions

The dot1x-mac-sessions for Clients authenticated or denied by a RADIUS server are aged out if no traffic is received from the Client MAC address for a certain period of time. After a Client dot1x-mac-session is aged out, the Client must be re-authenticated:

- **Permitted** dot1x-mac-sessions, which are the dot1x-mac-sessions for authenticated Clients, as well as for non-authenticated Clients whose ports have been placed in the restricted VLAN, are aged out if no traffic is received from the Client MAC address over the normal MAC aging interval on the Brocade device.
- **Denied** dot1x-mac-sessions, which are the dot1x-mac-sessions for non-authenticated Clients that are blocked by the Brocade device are aged out over a configurable software aging period. (Refer to the next section for more information on configuring the software aging period).

You can optionally disable aging of the permitted or denied dot1x-mac-sessions, or both, on the Brocade device.

To disable aging of the permitted dot1x-mac-sessions, enter the following command.

```
Brocade(config-dot1x)#mac-session-aging no-aging permitted-mac-only
```

Syntax: [no] mac-session-aging no-aging permitted-mac-only

To disable aging of the denied dot1x-mac-sessions, enter the following command.

```
Brocade(config-dot1x)#mac-session-aging no-aging denied-mac-only
```

Syntax: [no] mac-session-aging no-aging denied-mac-only

NOTE

This command enables aging of permitted sessions.

As a shortcut, use the command [no] **mac-session-aging** to enable or disable aging for permitted and denied sessions.

Specifying the aging time for blocked clients

When the Brocade device is configured to drop traffic from non-authenticated Clients, traffic from the blocked Clients is dropped in hardware, without being sent to the CPU. A Layer 2 CAM entry is created that drops traffic from the blocked Client MAC address in hardware. If no traffic is received from the blocked Client MAC address for a certain amount of time, this Layer 2 CAM entry is aged out. If traffic is subsequently received from the Client MAC address, then an attempt can be made to authenticate the Client again.

Aging of the Layer 2 CAM entry for a blocked Client MAC address occurs in two phases, known as **hardware aging** and **software aging**. The hardware aging period is fixed at 70 seconds and is non-configurable. The software aging time is configurable through the CLI.

Once the Brocade device stops receiving traffic from a blocked Client MAC address, the hardware aging begins and lasts for a fixed period of time. After the hardware aging period ends, the software aging period begins. The software aging period lasts for a configurable amount of time (by default 120 seconds). After the software aging period ends, the blocked Client MAC address ages out, and can be authenticated again if the Brocade device receives traffic from the Client MAC address.

Change the length of the software aging period for a blocked Client MAC address by entering the **mac-age-time** *<num>* command.

```
Brocade(config)#mac-age-time 180
```

Syntax: [no] **mac-age-time** *<seconds>*

You can specify from 1 – 65535 seconds. The default is 120 seconds.

Moving native VLAN mac-sessions to restrict VLAN

You can move the native VLAN mac-sessions to restrict VLAN on authentication failure. You can configure the option of overriding the dual-mode port native untagged VLAN with restricted VLAN in case 802.1x authentication fails and there is no RADIUS assigned VLAN. Use this command when you configure multi-device port authentication and 802.1X authentication configuration with dynamic VLAN assignment from RADIUS Server on the same port.

Example

```
Brocade(config-dot1x)# auth-fail-force-restrict
```

Syntax: [no] **auth-fail-force-restrict**

Clearing a dot1x-mac-session for a MAC address

You can clear the dot1x-mac-session for a specified MAC address, so that the Client with that MAC address can be re-authenticated by the RADIUS server.

Example

```
Brocade#clear dot1x mac-session 00e0.1234.abd4
```

Syntax: **clear dot1x mac-session** *<mac-address>*

MAC address filters for EAP frames

You can create MAC address filters to permit or deny EAP frames. To do this, you specify the Brocade device 802.1X group MAC address as the destination address in a MAC address filter, then apply the filter to an interface.

Creating MAC address filters for EAPS on most devices

For example, the following command creates a MAC address filter that denies frames with the destination MAC address of 0180.c200.0003, which is the 802.1X group MAC address on the Brocade device.

```
Brocade(config)#mac filter 1 deny any 0180.c200.0003 ffff.ffff.ffff
```

The following commands apply this filter to interface e 3/1.

```
Brocade(config)#interface e 3/11
Brocade(config-if-3/1)#mac filter-group 1
```

Refer to [“Defining MAC address filters”](#) on page 1857 for more information.

Configuring VLAN access for non-EAP-capable clients

You can configure the Brocade device to grant "guest" or restricted VLAN access to clients that do not support Extensible EAP. The restricted VLAN limits access to the network or applications, instead of blocking access to these services altogether.

When the Brocade device receives the first packet (non-EAP packet) from a client, the device waits for 10 seconds or the amount of time specified with the **timeout restrict-fwd-period** command. If the Brocade device does not receive subsequent packets after the timeout period, the device places the client on the restricted VLAN.

This feature is disabled by default. To enable this feature and change the timeout period, enter commands such as the following.

```
Brocade(config)#dot1x-enable
Brocade(config-dot1x)#restrict-forward-non-dot1x
Brocade(config-dot1x)#timeout restrict-fwd-period 15
```

Once the *success* timeout action is enabled, use the **no** form of the command to reset the RADIUS timeout behavior to *retry*.

Syntax: **timeout restrict-fwd-period** <num>

The <num> parameter is a value from 0 to 4294967295. The default value is 10.

802.1X accounting configuration

802.1X accounting enables the recording of information about 802.1X clients who were successfully authenticated and allowed access to the network. When 802.1X accounting is enabled on the Brocade device, it sends the following information to a RADIUS server whenever an authenticated 802.1X client (user) logs into or out of the Brocade device:

- The user name
- The session ID
- The user MAC address
- The authenticating physical port number

An Accounting Start packet is sent to the RADIUS server when a user is successfully authenticated. The Start packet indicates the start of a new session and contains the user MAC address and physical port number. The 802.1X session state will change to Authenticated and Permit after receiving a response from the accounting server for the accounting Start packet. If the Accounting service is not available, the 802.1X session status will change to Authenticated and Permit after a RADIUS timeout. The device will retry authentication requests three times (the default), or the number of times configured on the device.

An **Accounting Stop packet** is sent to the RADIUS server when one of the following events occur:

- The user logs off
- The port goes down
- The port is disabled
- The user fails to re-authenticate after a RADIUS timeout
- The 802.1X port control-auto configuration changes
- The MAC session clears (through use of the **clear dot1x mac-session** CLI command)

The Accounting Stop packet indicates the end of the session and the time the user logged out.

802.1X Accounting attributes for RADIUS

Brocade devices support the following RADIUS attributes for 802.1X accounting.

TABLE 295 802.1X accounting attributes for RADIUS

Attribute name	Attribute ID	Data Type	Description
Acct-Session-ID	44	Integer	The account session ID, which is a number from 1 to 4294967295.
Acct-Status-Type	40	integer	Indicates whether the accounting request marks the beginning (start) or end (stop) of the user service. 1 – Start 2 – Stop
Calling-Station-Id	31	string	The supplicant MAC address in ASCII format (upper case only), with octet values separated by a dash (-). For example 00-10-A4-23-19-C0
NAS-Port	5	integer	The physical port number.
NAS-Port-Type	61	integer	The physical port type.
user-name	1	string	The user name.

Enabling 802.1X accounting

To enable 802.1X accounting, enter the following command.

```
Brocade(config)#aaa accounting dot1x default start-stop radius none
```

Syntax: **aaa accounting dot1x default start-stop radius | none**

radius – Use the list of all RADIUS servers that support 802.1X for authentication.

none – Use no authentication. The client is automatically authenticated without the device using information supplied by the client.

NOTE

If you specify both **radius** and **none**, make sure **radius** comes before **none**.

Displaying 802.1X information

You can display the following 802.1X-related information:

- The 802.1X configuration on the device and on individual ports
- Statistics about the EAPOL frames passing through the device
- 802.1X-enabled ports dynamically assigned to a VLAN
- User-defined and dynamically applied MAC address filters and IP ACLs currently active on the device
- The 802.1X multiple-host configuration

Displaying 802.1X configuration information

To display information about the 802.1X configuration on the Brocade device, enter the **show dot1x** command.

```
Brocade#show dot1x
PAE Capability:    Authenticator Only
system-auth-control: Enable
re-authentication: Disable
global-filter-strict-security: Enable
quiet-period:     60 Seconds
tx-period:        30 Seconds
supertimeout:     30 Seconds
servertimeout:    30 Seconds
maxreq:           2
re-authperiod:    3600 Seconds
Protocol Version: 1
```

Syntax: show dot1x

The following table describes the information displayed by the **show dot1x** command.

TABLE 296 Output from the **show dot1x** command

Field	Description
PAE Capability	The Port Access Entity (PAE) role for the Brocade device. This is always "Authenticator Only".
system-auth-control	Whether system authentication control is enabled on the device. The dot1x-enable command enables system authentication control on the device.
re-authentication	Whether periodic re-authentication is enabled on the device. Refer to "Configuring periodic re-authentication" on page 1811. When periodic re-authentication is enabled, the device automatically re-authenticates Clients every 3,600 seconds by default.
global-filter-strict-security	Whether strict security mode is enabled or disabled globally. Refer to "Disabling and enabling strict security mode for dynamic filter assignment" on page 1807.
quiet-period	When the Brocade device is unable to authenticate a Client, the amount of time the Brocade device waits before trying again (default 60 seconds). Refer to "Setting the quiet period" on page 1812 for information on how to change this setting.

TABLE 296 Output from the **show dot1x** command (Continued)

Field	Description
tx-period	When a Client does not send back an EAP-response/identity frame, the amount of time the Brocade device waits before retransmitting the EAP-request/identity frame to a Client (default 30 seconds). Refer to “Setting the wait interval for EAP frame retransmissions” on page 1813 for information on how to change this setting.
supp-timeout	When a Client does not respond to an EAP-request frame, the amount of time before the Brocade device retransmits the frame. Refer to “Setting the wait interval for EAP frame retransmissions” on page 1814 for information on how to change this setting.
server-timeout	When the Authentication Server does not respond to a message sent from the Client, the amount of time before the Brocade device retransmits the message. Refer to “Specifying a timeout for retransmission of messages to the authentication server” on page 1814 for information on how to change this setting.
maxreq	The number of times the Brocade device retransmits an EAP-request/identity frame if it does not receive an EAP-response/identity frame from a Client (default 2 times). Refer to “Setting the maximum number of EAP frame retransmissions” on page 1813 for information on how to change this setting.
re-authperiod	How often the device automatically re-authenticates Clients when periodic re-authentication is enabled (default 3,600 seconds). Refer to “Configuring periodic re-authentication” on page 1811 for information on how to change this setting.
Protocol Version	The version of the 802.1X protocol in use on the device.

To display information about the 802.1X configuration on an individual port, enter the **show dot1x configuration ethernet** command.

```
Brocade#show dot1x configuration ethernet 1/3
Port-Control                : control-auto
filter strict security      : Enable
Action on RADIUS timeout   : Treat as a failed authentication
  re-authenticate          : 150 seconds
PVID State                  : Normal (101)
Original PVID               : 101
PVID mac total              : 1
PVID mac authorized         : 1
num mac sessions            : 1
num mac authorized          : 1
Number of Auth filter       : 0
```

Syntax: **show dot1x config ethernet** <port>

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

The following additional information is displayed in the **show dot1x config** command for an interface.

TABLE 297 Output from the **show dot1x config** command for an interface

Field	Description
Authenticator PAE state	<p>The current status of the Authenticator PAE state machine. This can be INITIALIZE, DISCONNECTED, CONNECTING, AUTHENTICATING, AUTHENTICATED, ABORTING, HELD, FORCE_AUTH, or FORCE_UNAUTH.</p> <p>NOTE: When the Authenticator PAE state machine is in the AUTHENTICATING state, if the reAuthenticate, eapStart, eapLogoff, or authTimeout parameters are set to TRUE, it may place the Authenticator PAE state machine indefinitely in the ABORTING state. If this should happen, use the dot1x initialize command to initialize 802.1X port security on the port, or unplug the Client or hub connected to the port, then reconnect it.</p>
Backend Authentication state	The current status of the Backend Authentication state machine. This can be REQUEST, RESPONSE, SUCCESS, FAIL, TIMEOUT, IDLE, or INITIALIZE.
AdminControlledDirections	Indicates whether an unauthorized controlled port exerts control over communication in both directions (disabling both reception of incoming frames and transmission of outgoing frames), or just in the incoming direction (disabling only reception of incoming frames). On Brocade devices, this parameter is set to BOTH.
OperControlledDirections	The setting for the OperControlledDirections parameter, as defined in the 802.1X standard. According to the 802.1X standard, if the AdminControlledDirections parameter is set to BOTH, the OperControlledDirections parameter is unconditionally set to BOTH. Since the AdminControlledDirections parameter on Brocade devices is always set to BOTH, the OperControlledDirections parameter is also set to BOTH.
AuthControlledPortControl	The port control type configured for the interface. If set to auto, authentication is activated on the 802.1X-enabled interface.
AuthControlledPortStatus	The current status of the interface controlled port either authorized or unauthorized.
multiple-hosts	Whether the port is configured to allow multiple Supplicants accessing the interface on the Brocade device through a hub. Refer to “Allowing access to multiple hosts” on page 1815 for information on how to change this setting.

Displaying 802.1X statistics

To display 802.1X statistics for an individual port, enter the **show dot1x statistics** command.

```
Brocade#show dot1x statistics e 3/3
```

```
Port 3/3 Statistics:
RX EAPOL Start:      0
RX EAPOL Logoff:     0
RX EAPOL Invalid:    0
RX EAPOL Total:      0
RX EAP Resp/Id:      0
RX EAP Resp other than Resp/Id:  0
RX EAP Length Error:  0
Last EAPOL Version:  0
Last EAPOL Source:   0007.9550.0B83
TX EAPOL Total:      217
TX EAP Req/Id:       163
TX EAP Req other than Req/Id:    0
```

Syntax: **show dot1x statistics ethernet** <port>

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

The following table describes the information displayed by the **show dot1x statistics** command for an interface.

TABLE 298 Output from the **show dot1x statistics** command

Field	Statistics
RX EAPOL Start	The number of EAPOL-Start frames received on the port.
RX EAPOL Logoff	The number of EAPOL-Logoff frames received on the port.
RX EAPOL Invalid	The number of invalid EAPOL frames received on the port.
RX EAPOL Total	The total number of EAPOL frames received on the port.
RX EAP Resp/Id	The number of EAP-Response/Identity frames received on the port
RX EAP Resp other than Resp/Id	The total number of EAPOL-Response frames received on the port that were not EAP-Response/Identity frames.
RX EAP Length Error	The number of EAPOL frames received on the port that have an invalid packet body length.
Last EAPOL Version	The version number of the last EAPOL frame received on the port.
Last EAPOL Source	The source MAC address in the last EAPOL frame received on the port.
TX EAPOL Total	The total number of EAPOL frames transmitted on the port.
TX EAP Req/Id	The number of EAP-Request/Identity frames transmitted on the port.
TX EAP Req other than Req/Id	The number of EAP-Request frames transmitted on the port that were not EAP-Request/Identity frames.

Clearing 802.1X statistics

You can clear the 802.1X statistics counters on all interfaces at once, on individual interfaces, or on a range of interfaces.

For example, to clear the 802.1X statistics counters on all interfaces on the device, enter the **clear dot1x statistics all** command.

```
Brocade#clear dot1x statistics all
```

Syntax: **clear dot1x statistics all**

To clear the 802.1X statistics counters on interface e 3/11, enter the following command.

```
Brocade#clear dot1x statistics e 3/11
```

Syntax: **clear dot1x statistics ethernet <port>**

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Displaying dynamically-assigned VLAN information

The **show interface** command displays the VLAN to which an 802.1X-enabled port has been dynamically assigned, as well as the port from which it was moved (that is, the port default VLAN).

The following example of the **show interface** command indicates the port dynamically assigned VLAN. Information about the dynamically assigned VLAN is shown in bold type.

```
Brocade#show interface e 12/2
FastEthernet12/2 is up, line protocol is up
  Hardware is FastEthernet, address is 0204.80a0.4681 (bia 0204.80a0.4681)
  Configured speed auto, actual 100Mbit, configured duplex fdx, actual fdx
  Member of L2 VLAN ID 2 (dot1x-RADIUS assigned), original L2 VLAN ID is 1,
  port is untagged, port state is FORWARDING
  STP configured to ON, priority is level0, flow control enabled
  mirror disabled, monitor disabled
  Not member of any active trunks
  Not member of any configured trunks
  No port name
  MTU 1518 bytes
  300 second input rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
  300 second output rate: 256 bits/sec, 0 packets/sec, 0.00% utilization
  3 packets input, 192 bytes, 0 no buffer
  Received 0 broadcasts, 0 multicasts, 3 unicasts
  0 input errors, 0 CRC, 0 frame, 0 ignored
  0 runts, 0 giants, DMA received 3 packets
  919 packets output, 58816 bytes, 0 underruns
  Transmitted 1 broadcasts, 916 multicasts, 2 unicasts
  0 output errors, 0 collisions, DMA transmitted 919 packets
```

In this example, the 802.1X-enabled port has been moved from VLAN 1 to VLAN 2. When the client disconnects, the port will be moved back to VLAN 1.

The **show run** command also indicates the VLAN to which the port has been dynamically assigned. The output can differ depending on whether GARP VLAN Registration Protocol (GVRP) is enabled on the device:

- **Without GVRP** – When you enter the **show run** command, the output indicates that the port is a member of the VLAN to which it was dynamically assigned through 802.1X. If you then enter the **write memory** command, the VLAN to which the port is currently assigned becomes the port default VLAN in the device configuration.
- **With GVRP** – When you enter the **show run** command, if the VLAN name supplied by the RADIUS server corresponds to a VLAN learned through GVRP, then the output indicates that the port is a member of the VLAN to which it was originally assigned (not the VLAN to which it was dynamically assigned).

If the VLAN name supplied by the RADIUS server corresponds to a statically configured VLAN, the output indicates that the port is a member of the VLAN to which it was dynamically assigned through 802.1X. If you then enter the **write memory** command, the VLAN to which the port is currently assigned becomes the port default VLAN in the device configuration.

Displaying information about dynamically applied MAC address filters and IP ACLs

You can display information about currently active user-defined and dynamically applied MAC address filters and IP ACLs.

Displaying user-defined MAC address filters and IP ACLs

To display the user-defined MAC address filters active on the device, enter the following command.

```
Brocade#show dot1x mac-address filter
```

```
Port 1/3 (User defined MAC Address Filter) :  
    mac filter 1 permit any any
```

Syntax: show dot1x mac-address-filter

To display the user-defined IP ACLs active on the device, enter the **show dot1x ip-ACL** command.

```
Brocade#show dot1x ip-ACL
```

```
Port 1/3 (User defined IP ACLs):
```

```
Extended IP access list Port_1/3_E_IN  
permit udp any any
```

```
Extended IP access list Port_1/3_E_OUT  
permit udp any any
```

Syntax: show dot1x ip-ACL

Displaying dynamically applied MAC address filters and IP ACLs

To display the dynamically applied MAC address filters active on an interface, enter a command such as the following.

```
Brocade#show dot1x mac-address-filter e 1/3
```

```
Port 1/3 MAC Address Filter information:
  802.1X Dynamic MAC Address Filter :
    mac filter-group 2
  Port default MAC Address Filter:
    No mac address filter is set
```

Syntax: `show dot1x mac-address-filter all | ethernet <port>`

The **all** keyword displays all dynamically applied MAC address filters active on the device.

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

To display the dynamically applied IP ACLs active on an interface, enter a command such as the following.

```
Brocade#show dot1x ip-ACL e 1/3
```

```
Port 1/3 IP ACL information:
  802.1X dynamic IP ACL (user defined) in:
    ip access-list extended Port_1/3_E_IN in
  Port default IP ACL in:
    No inbound ip access-list is set
  802.1X dynamic IP ACL (user defined) out:
    ip access-list extended Port_1/3_E_OUT out
  Port default IP ACL out:
    No outbound ip access-list is set
```

Syntax: `show dot1x ip-ACL all | ethernet <port>`

The **all** keyword displays all dynamically applied IP ACLs active on the device.

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Displaying the status of strict security mode

The output of the **show dot1x** and **show dot1x config** commands indicate whether strict security mode is enabled or disabled globally and on an interface.

Displaying the status of strict security mode globally on the device

To display the status of strict security mode globally on the device, enter the **show dot1x** command.

```
Brocade#show dot1x
PAE Capability:      Authenticator Only
system-auth-control: Enable
re-authentication: Disable
global-filter-strict-security: Enable
quiet-period:       60 Seconds
tx-period:          30 Seconds
supertimeout:       30 Seconds
servertimeout:      30 Seconds
maxreq:             2
re-authperiod:      3600 Seconds
security-hold-time: 60 Seconds
Protocol Version:   1
```

Syntax: show dot1x

Displaying the status of strict security mode on an interface

To display the status of strict security mode on an interface, enter a command such as the following

```
Brocade#show dot1x config e 1/3

Port 1/3 Configuration:
Authenticator PAE state:      AUTHENTICATED
Backend Authentication state: IDLE
AdminControlledDirections:    BOTH
OperControlledDirections:     BOTH
AuthControlledPortControl:    Auto
AuthControlledPortStatus:     authorized
quiet-period:                 60 Seconds
tx-period:                     30 Seconds
supertimeout:                 30 Seconds
servertimeout:                30 Seconds
maxreq:                        2
re-authperiod:                3600 Seconds
security-hold-time:           60 Seconds
re-authentication:            Disable
multiple-hosts:               Disable
filter-strict-security: Enable
Protocol Version:             1
```

Syntax: show dot1x config ethernet <port>

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*

- FESX compact switches – *portnum*

Displaying 802.1X multiple-host authentication information

You can display the following information about 802.1X multiple-host authentication:

- Information about the 802.1X multiple-host configuration
- The dot1x-mac-sessions on each port
- The number of users connected on each port in a 802.1X multiple-host configuration

Displaying 802.1X multiple-host configuration information

The output of the **show dot1x** and **show dot1x config** commands displays information related to 802.1X multiple-host authentication.

The following is an example of the output of the **show dot1x** command. The information related to multiple-host authentication is highlighted in bold.

```
Brocade#show dot1x
```

```

Number of Ports enabled      : 2
Re-Authentication           : Enabled
Authentication-fail-action : Restricted VLAN
Authentication Failure VLAN : 111
Mac Session Aging          : Disabled for permitted MAC sessions
Mac Session max-age        : 60 seconds
Protocol Version            : 1
quiet-period                 : 5 Seconds
tx-period                    : 30 Seconds
supptimeout                  : 30 Seconds
servertimeout                : 30 Seconds
maxreq                       : 2
re-authperiod                : 3600 Seconds
security-hold-time           : 60 Seconds
re-authentication            : Enable
Flow based multi-user policy : Disable
```

Syntax: **show dot1x**

[Table 299](#) describes the bold fields in the display.

TABLE 299 Output from the **show dot1x** command for multiple host authentication

Field	Description
Authentication-fail-action	The configured authentication-failure action. This can be Restricted VLAN or Block Traffic.
Authentication Failure VLAN	If the authentication-failure action is Restricted VLAN, the ID of the VLAN to which unsuccessfully authenticated Client ports are assigned.
Mac Session Aging	Whether aging for dot1x-mac-sessions has been enabled or disabled for permitted or denied dot1x-mac-sessions.

TABLE 299 Output from the **show dot1x** command for multiple host authentication (Continued)

Field	Description
Mac Session max-age	The configured software aging time for dot1x-mac-sessions.
Flow based multi-user policy	The dynamically assigned IP ACLs and MAC address filters used in the 802.1X multiple-host configuration.

The output of the **show dot1x config** command for an interface displays the configured port control for the interface. This command also displays information related to 802.1X multiple host-authentication.

The following is an example of the output of the **show dot1x config** command for an interface.

```
Brocade#show dot1x config e 3/1

Port-Control                : control-auto
filter strict security      : Enable
PVID State                  : Restricted (10)
Original PVID               : 10
PVID mac total              : 1
PVID mac authorized         : 0
num mac sessions            : 1
num mac authorized          : 0
```

Syntax: **show dot1x config ethernet** <port>

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

The following table lists the fields in the display.

TABLE 300 Output from the **show dot1x config** command

Field	Description
Port-Control	The configured port control type for the interface. This can be one of the following: force-authorized – The controlled port is placed unconditionally in the authorized state, allowing all traffic. This is the default state for ports on the Brocade device. force-unauthorized – The controlled port is placed unconditionally in the unauthorized state. No authentication takes place for any connected 802.1X Clients. auto – The authentication status for each 802.1X Client depends on the authentication status returned from the RADIUS server.
filter strict security	Whether strict security mode is enabled or disabled on the interface.
PVID State	The port default VLAN ID (PVID) and the state of the port PVID. The PVID state can be one of the following Normal – The port PVID is not set by a RADIUS server, nor is it the restricted VLAN. RADIUS – The port PVID was dynamically assigned by a RADIUS server. RESTRICTED – The port PVID is the restricted VLAN.
Original PVID	The originally configured (not dynamically assigned) PVID for the port.
PVID mac total	The number of devices transmitting untagged traffic on the port PVID.

TABLE 300 Output from the **show dot1x config** command (Continued)

Field	Description
PVID mac authorized	The number of devices transmitting untagged traffic on the port PVID as a result of dynamic VLAN assignment.
num mac sessions	The number of dot1x-mac-sessions on the port.
num mac authorized	The number of authorized dot1x-mac-sessions on the port.

Displaying information about the dot1x MAC sessions on each port

The **show dot1x mac-session** command displays information about the dot1x-mac-sessions on each port on the device. The output also shows the authenticator PAE state.

Example

```
Brocade#show dot1x mac-session
```

Port	MAC/(username)	Vlan	Auth State	ACL	Age	PAE State
1	0010.a498.24f7 :User	10	permit	none	S20	AUTHENTICATED

Syntax: **show dot1x mac-session**

[Table 301](#) lists the new fields in the display.

TABLE 301 Output from the **show dot1x mac-session** command

Field	Description
Port	The port on which the dot1x-mac-session exists.
MAC/ (username)	The MAC address of the Client and the username used for RADIUS authentication.
Vlan	The VLAN to which the port is currently assigned.
Auth-State	The authentication state of the dot1x-mac-session. This can be one of the following permit – The Client has been successfully authenticated, and traffic from the Client is being forwarded normally. blocked – Authentication failed for the Client, and traffic from the Client is being dropped in hardware. restricted – Authentication failed for the Client, but traffic from the Client is allowed in the restricted VLAN only. init - The Client is in is in the process of 802.1X authentication, or has not started the authentication process.
Age	The software age of the dot1x-mac-session.
PAE State	The current status of the Authenticator PAE state machine. This can be INITIALIZE, DISCONNECTED, CONNECTING, AUTHENTICATING, AUTHENTICATED, ABORTING, HELD, FORCE_AUTH, or FORCE_UNAUTH. NOTE: When the Authenticator PAE state machine is in the AUTHENTICATING state, if the reAuthenticate, eapStart, eapLogoff, or authTimeout parameters are set to TRUE, it may place the Authenticator PAE state machine indefinitely in the ABORTING state. If this should happen, use the dot1x initialize command to initialize 802.1X port security on the port, or unplug the Client or hub connected to the port, then reconnect it.

Displaying information about the ports in an 802.1X multiple-host configuration

To display information about the ports in an 802.1X multiple-host configuration, enter the **sho do mac-s br** command.

```
Brocade(config-dot1x)#sh do mac-s br
```

Port	Number of users	Number of Authorized users	Dynamic VLAN	Dynamic ACL	Dynamic MAC-Filt
1/1/1	0	0	no	no	no
1/1/2	0	0	no	no	no
1/1/3	0	0	no	no	no
1/1/4	0	0	no	no	no
1/1/5	0	0	no	no	no
1/1/6	0	0	no	no	no
1/1/7	0	0	no	no	no
1/1/8	0	0	no	no	no
1/1/9	0	0	no	no	no
1/1/10	0	0	no	no	no
1/1/11	0	0	no	no	no
1/1/12	0	0	no	no	no
1/1/13	0	0	no	no	no
1/1/14	0	0	no	no	no
1/1/15	0	0	no	no	no
1/1/16	0	0	no	no	no

Syntax: show dot1x mac-session brief

The following table describes the information displayed by the **show dot1x mac-session brief** command.

TABLE 302 Output from the **show dot1x mac-session brief** command

Field	Description
Port	Information about the users connected to each port.
Number of users	The number of users connected to the port.
Number of Authorized users	The number of users connected to the port that have been successfully authenticated.
Dynamic VLAN	Whether the port is a member of a RADIUS-specified VLAN.
Dynamic Filters	Whether RADIUS-specified IP ACLs or MAC address filters have been applied to the port.

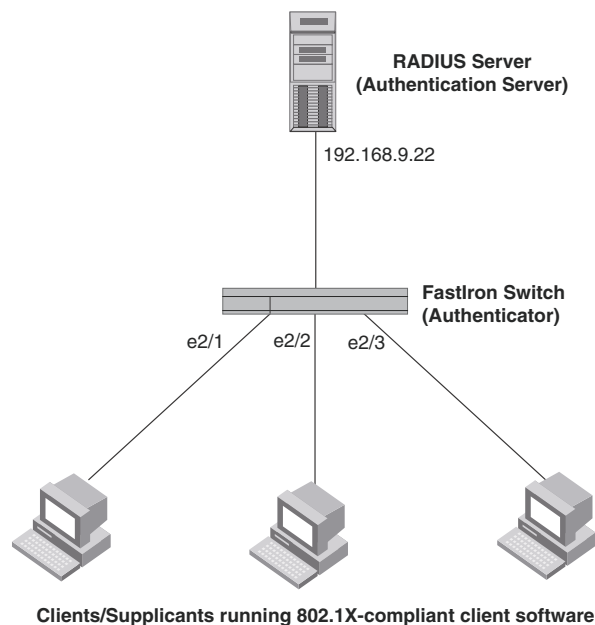

Sample 802.1X configurations

This section illustrates a sample point-to-point configuration and a sample hub configuration that use 802.1X port security.

Point-to-point configuration

[Figure 193](#) illustrates a sample 802.1X configuration with Clients connected to three ports on the Brocade device. In a point-to-point configuration, only one 802.1X Client can be connected to each port.

FIGURE 193 Sample point-to-point 802.1X configuration

Same point-to-point 802.1x configuration

The following commands configure the Brocade device in [Figure 193](#)

```

Brocade(config)#aaa authentication dot1x default radius
Brocade(config)#radius-server host 192.168.9.22 auth-port 1812 acct-port 1813
Brocade(config)#dot1x-enable e 1 to 3
Brocade(config-dot1x)#re-authentication
Brocade(config-dot1x)#timeout re-authperiod 2000
Brocade(config-dot1x)#timeout quiet-period 30
Brocade(config-dot1x)#timeout tx-period 60
Brocade(config-dot1x)#maxreq 6
Brocade(config-dot1x)#exit
Brocade(config)#interface e 1
Brocade(config-if-e1000-1)#dot1x port-control auto
Brocade(config-if-e1000-1)#exit
Brocade(config)#interface e 2
Brocade(config-if-e1000-2)#dot1x port-control auto
Brocade(config-if-e1000-2)#exit

```

```
Brocade(config)#interface e 3
Brocade(config-if-e1000-3)#dot1x port-control auto
Brocade(config-if-e1000-3)#exit
```

Hub configuration

Figure 194 illustrates a configuration where three 802.1X-enabled Clients are connected to a hub, which is connected to a port on the Brocade device. The configuration is similar to that in Figure 193, except that 802.1X port security is enabled on only one port, and the **multiple-hosts** command is used to allow multiple Clients on the port.

FIGURE 194 Sample 802.1X configuration using a hub

Sample 802.1x configuration using a hub

The following commands configure the Brocade device in Figure 194

```
Brocade(config)#aaa authentication dot1x default radius
Brocade(config)#radius-server host 192.168.9.22 auth-port 1812 acct-port 1813
default key mirabeau dot1x
Brocade(config)#dot1x-enable e 1
Brocade(config-dot1x)#re-authentication
Brocade(config-dot1x)#timeout re-authperiod 2000
Brocade(config-dot1x)#timeout quiet-period 30
Brocade(config-dot1x)#timeout tx-period 60
Brocade(config-dot1x)#maxreq 6
Brocade(config-dot1x)#exit
Brocade(config)#interface e 1
Brocade(config-if-e1000-1)#dot1x port-control auto
Brocade(config-if-e1000-1)#exit
```

802.1X Authentication with dynamic VLAN assignment

Figure 195 illustrates 802.1X authentication with dynamic VLAN assignment. In this configuration, two user PCs are connected to a hub, which is connected to port e2. Port e2 is configured as a dual-mode port. Both PCs transmit untagged traffic. The profile for User 1 on the RADIUS server specifies that User 1 PC should be dynamically assigned to VLAN 3. The RADIUS profile for User 2 on the RADIUS server specifies that User 2 PC should be dynamically assigned to VLAN 20.

FIGURE 195 Sample configuration using 802.1X authentication with dynamic VLAN assignment

In this example, the PVID for port e2 would be changed based on the first host to be successfully authenticated. If User 1 is authenticated first, then the PVID for port e2 is changed to VLAN 3. If User 2 is authenticated first, then the PVID for port e2 is changed to VLAN 20. Since a PVID cannot be changed by RADIUS authentication after it has been dynamically assigned, if User 2 is authenticated after the port PVID was changed to VLAN 3, then User 2 would not be able to gain access to the network.

If there were only one device connected to the port, and authentication failed for that device, it could be placed into the restricted VLAN, where it could gain access to the network.

The portion of the running-config related to 802.1X authentication is as follows.

```

dot1x-enable
 re-authentication
 servertimeout 10
 timeout re-authperiod 10
 auth-fail-action restricted-vlan
 auth-fail-vlanid 1023
 mac-session-aging no-aging permitted-mac-only
 enable ethe 2 to 4
!
!

```

```
!  
interface ethernet 2  
  dot1x port-control auto  
  dual-mode
```

If User 1 is successfully authenticated before User 2, the PVID for port e2 would be changed from the default VLAN to VLAN 3.

Had User 2 been the first to be successfully authenticated, the PVID would be changed to 20, and User 1 would not be able to gain access to the network. If there were only one device connected to the port that was sending untagged traffic, and 802.1X authentication failed for that device, it would be placed in the restricted VLAN 1023, and would be able to gain access to the network.

Multi-device port authentication and 802.1X security on the same port

You can configure the Brocade device to use multi-device port authentication and 802.1X security on the same port:

- The multi-device port authentication feature allows you to configure a Brocade device to forward or block traffic from a MAC address based on information received from a RADIUS server. Incoming traffic originating from a given MAC address is switched or forwarded by the device only if the source MAC address is successfully authenticated by a RADIUS server. The MAC address itself is used as the username and password for RADIUS authentication. A connecting user does not need to provide a specific username and password to gain access to the network.
- The IEEE 802.1X standard is a means for authenticating devices attached to LAN ports. Using 802.1X port security, you can configure a Brocade device to grant access to a port based on information supplied by a client to an authentication server.

When both of these features are enabled on the same port, multi-device port authentication is performed prior to 802.1X authentication. If multi-device port authentication is successful, 802.1X authentication may be performed, based on the configuration of a vendor-specific attribute (VSA) in the profile for the MAC address on the RADIUS server.

For more information, including configuration examples, see [“Multi-device port authentication and 802.1X security on the same port”](#) on page 1853.

MAC Port Security

Table 303 lists the individual Brocade FastIron switches and the Media Access Control (MAC) port security features they support. These features are supported in the Layer 2, base Layer 3, edge Layer 3, and full Layer 3 software images, except where explicitly noted.

TABLE 303 Supported MAC port security features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
MAC port security	Yes	Yes	Yes	Yes	Yes
Setting the maximum number of secure MAC addresses on an interface	Yes	Yes	Yes	Yes	Yes
Setting the port security age timer	Yes	Yes	Yes	Yes	Yes
Specifying secure MAC addresses	Yes	Yes	Yes	Yes	Yes
Autosaving secure MAC addresses to the startup-config file	Yes	Yes	Yes	Yes	Yes
Specifying the action taken when a security violation occurs	Yes	Yes	Yes	Yes	Yes
Clearing port security statistics	Yes	Yes	Yes	Yes	Yes

This chapter describes how to configure Brocade devices to learn “secure” MAC addresses on an interface so that the interface will forward only packets that match the secure addresses.

MAC port security overview

You can configure the Brocade device to learn “secure” MAC addresses on an interface. The interface will forward only packets with source MAC addresses that match these learned secure addresses. The secure MAC addresses can be specified manually, or the Brocade device can learn them automatically. After the device reaches the limit for the number of secure MAC addresses it can learn on the interface, if the interface then receives a packet with a source MAC address that does not match the learned addresses, it is considered a security violation.

When a security violation occurs, a Syslog entry and an SNMP trap are generated. In addition, the device takes one of two actions: it either drops packets from the violating address (and allows packets from the secure addresses), or disables the port for a specified amount of time. You specify which of these actions takes place.

The secure MAC addresses are not flushed when an interface is disabled and re-enabled on FastIron X Series devices. The secure MAC addresses are flushed when an interface is disabled and re-enabled on FCX and ICX devices.

The secure addresses can be kept secure permanently (the default), or can be configured to age out, at which time they are no longer secure. You can configure the device to automatically save the secure MAC address list to the startup-config file at specified intervals, allowing addresses to be kept secure across system restarts.

Local and global resources used for MAC port security

The MAC port security feature uses a concept of local and global “resources” to determine how many MAC addresses can be secured on each interface. In this context, a “resource” is the ability to store one secure MAC address entry. Each interface is allocated 64 local resources. Additional global resources are shared among all interfaces on the device.

When the MAC port security feature is enabled on an interface, the interface can store one secure MAC address. You can increase the number of MAC addresses that can be secured using local resources to a maximum of 64.

Besides the maximum of 64 local resources available to an interface, there are additional global resources. Depending on flash memory size, a device can have 1024, 2048, or 4096 global resources available. When an interface has secured enough MAC addresses to reach its limit for local resources, it can secure additional MAC addresses by using global resources. Global resources are shared among all the interfaces on a first-come, first-served basis.

The maximum number of MAC addresses any single interface can secure is 64 (the maximum number of local resources available to the interface), plus the number of global resources not allocated to other interfaces.

Configuration notes and feature limitations for MAC port security

The following limitations apply to this feature:

- MAC port security applies only to Ethernet interfaces.
- MAC port security is not supported on static trunk group members or ports that are configured for link aggregation.
- MAC port security is not supported on 802.1X port security-enabled ports.

- Brocade devices do not support the **reserved-vlan-id** <num> command, which changes the default VLAN ID for the MAC port security feature.
- The SNMP trap generated for restricted MAC addresses indicates the VLAN ID associated with the MAC address, as well as the port number and MAC address.
- MAC port security is not supported on ports that have multi-device port authentication enabled.
- The first packet from each new secure MAC address is dropped if secure MAC addresses are learned dynamically.

MAC port security configuration

To configure the MAC port security feature, perform the following tasks:

- Enable the MAC port security feature
- Set the maximum number of secure MAC addresses for an interface
- Set the port security age timer
- Specify secure MAC addresses
- Configure the device to automatically save secure MAC addresses to the startup-config file
- Specify the action taken when a security violation occurs

Enabling the MAC port security feature

By default, the MAC port security feature is disabled on all interfaces. You can enable or disable the feature on all interfaces at once, or on individual interfaces.

To enable the feature on all interfaces at once, enter the following commands.

```
Brocade(config)#port security
Brocade(config-port-security)#enable
```

To disable the feature on all interfaces at once, enter the following commands.

```
Brocade(config)#port security
Brocade(config-port-security)#no enable
```

To enable the feature on a specific interface, enter the following commands.

```
Brocade(config)#interface ethernet 7/11
Brocade(config-if-e1000-7/11)#port security
Brocade(config-port-security-e1000-7/11)#enable
```

Syntax: port security

Syntax: [no] enable

Setting the maximum number of secure MAC addresses for an interface

When MAC port security is enabled, an interface can store one secure MAC address. You can increase the number of MAC addresses that can be stored to a maximum of 64, plus the total number of global resources available.

For example, to configure interface 7/11 to have a maximum of 10 secure MAC addresses, enter the following commands.

```
Brocade(config)#interface ethernet 7/11
Brocade(config-if-e1000-7/11)#port security
Brocade(config-port-security-e1000-7/11)#maximum 10
```

Syntax: `maximum <number-of-addresses>`

The `<number-of-addresses>` parameter can be set to a number from 0 through 64 plus (the total number of global resources available). The total number of global resources is 2048 or 4096, depending on flash memory size. Setting the parameter to 0 prevents any addresses from being learned. The default is 1.

Setting the port security age timer

By default, learned MAC addresses stay secure indefinitely. You can optionally configure the device to age out secure MAC addresses after a specified amount of time.

To set the port security age timer to 10 minutes on all interfaces, enter the following commands.

```
Brocade(config)#port security
Brocade(config-port-security)#age 10
```

To set the port security age timer to 10 minutes on a specific interface, enter the following commands.

```
Brocade(config)#interface ethernet 7/11
Brocade(config-if-e1000-7/11)#port security
Brocade(config-port-security-e1000-7/11)#age 10
```

Syntax: `[no] age <minutes>`

The `<minutes>` variable specifies a range from 0 through 1440 minutes. The default is 0 (never age out secure MAC addresses).

NOTE

Even though you can set age time to specific ports independent of the device-level setting, the actual age timer will take the greater of the two values. Thus, if you set the age timer to 3 minutes for the port, and 10 minutes for the device, the port MAC aging happens in 10 minutes (the device-level setting), which is greater than the port setting that you have configured.

Specifying secure MAC addresses

You can configure secure MAC addresses on tagged and untagged interfaces.

On an untagged interface

To specify a secure MAC address on an untagged interface, enter commands such as the following.

```
Brocade(config)#interface ethernet 7/11
Brocade(config-if-e1000-7/11)#port security
Brocade(config-port-security-e1000-7/11)#secure-mac-address 0050.DA18.747C
```

Syntax: [no] **secure-mac-address** <mac-address>

On a tagged interface

When specifying a secure MAC address on a tagged interface, you must also specify the VLAN ID. To do so, enter commands such as the following.

```
Brocade(config)#interface ethernet 7/11
Brocade(config-if-e1000-7/11)#port security
Brocade(config-port-security-e1000-7/11)#secure-mac-address 0050.DA18.747C 2
```

Syntax: [no] **secure-mac-address** <mac-address> <vlan-ID>

NOTE

If MAC port security is enabled on a port and you change the VLAN membership of the port, make sure that you also change the VLAN ID specified in the **secure-mac-address** configuration statement for the port.

When a secure MAC address is applied to a tagged port, the VLAN ID is generated for both tagged and untagged ports. When you display the configuration, you will see an entry for the secure MAC addresses. For example, you might see an entry similar to the following line.

```
secure-mac-address 0000.1111.2222 10
```

This line means that MAC address 0000.1111.2222 on VLAN 10 is a secure MAC address.

Autosaving secure MAC addresses to the startup configuration

Learned MAC addresses can automatically be saved to the startup configuration at specified intervals. The autosave feature saves learned MAC addresses by copying the running configuration to the startup configuration.

For example, to automatically save learned secure MAC addresses every 20 minutes, enter the following commands.

```
Brocade(config)#port security
Brocade(config-port-security)#autosave 20
```

Syntax: [no] **autosave** <minutes>

The <minutes> variable can be from 15 through 1440 minutes. By default, secure MAC addresses are not autosaved to the startup-config file.

If you change the autosave interval, the next save happens according to the old interval, then the new interval takes effect. To change the interval immediately, disable autosave by entering the **no autosave** command, then configure the new autosave interval using the **autosave** command.

Specifying the action taken when a security violation occurs

A security violation can occur when a user tries to connect to a port where a MAC address is already locked, or the maximum number of secure MAC addresses has been exceeded. When a security violation occurs, an SNMP trap and Syslog message are generated.

You can configure the device to take one of two actions when a security violation occurs; either drop packets from the violating address (and allow packets from secure addresses), or disable the port for a specified time.

Dropping packets from a violating address

To configure the device to drop packets from a violating address and allow packets from secure addresses, enter the following commands.

```
Brocade(config)#interface ethernet 7/11
Brocade(config-if-e1000-7/11)#port security
Brocade(config-port-security-e1000-7/11)#violation restrict
```

Syntax: violation [restrict]

NOTE

When the **restrict** option is used, the maximum number of MAC addresses that can be restricted is 128. If the number of violating MAC addresses exceeds this number, the port is shut down. An SNMP trap and the following Syslog message are generated: "Port Security violation restrict limit 128 exceeded on interface ethernet <port_id>". This is followed by a port shutdown Syslog message and trap.

Specifying the period of time to drop packets from a violating address

To specify the number of minutes that the device drops packets from a violating address, use commands similar to the following.

```
Brocade(config)#interface ethernet 7/11
Brocade(config-if-e1000-7/11)#port security
Brocade(config-port-security-e1000-7/11)#violation restrict 5
```

Syntax: violation restrict <age>

The <age> variable can be from 0 through 1440 minutes. The default is 5 minutes. Specifying 0 drops packets from the violating address permanently.

Aging for restricted MAC addresses is done in software. There can be a worst case inaccuracy of one minute from the specified time.

The restricted MAC addresses are denied in hardware.

Disabling the port for a specified amount of time

You can configure the device to disable the port for a specified amount of time when a security violation occurs.

To shut down the port for 5 minutes when a security violation occurs, enter the following commands.

```
Brocade(config)#interface ethernet 7/11
Brocade(config-if-e1000-7/11)#port security
Brocade(config-port-security-e1000-7/11)#violation shutdown 5
```

Syntax: `violation shutdown <minutes>`

The minutes can be from 0 through 1440 minutes. Specifying 0 shuts down the port permanently when a security violation occurs.

Clearing port security statistics

You can clear restricted MAC addresses and violation statistics from ports on all ports or on individual ports.

Clearing restricted MAC addresses

To clear all restricted MAC addresses globally, enter the **clear port security restricted-macs all** command.

```
Brocade#clear port security restricted-macs all
```

To clear restricted MAC addresses on a specific port, enter a command such as the following.

```
Brocade#clear port security restricted-macs ethernet 5
```

Syntax: `clear port security restricted-macs all | ethernet <port>`

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Clearing violation statistics

To clear violation statistics globally, enter the **clear port security statistics all** command.

```
Brocade#clear port security statistics all
```

To clear violation statistics on a specific port, enter a command such as the following.

```
Brocade#clear port security statistics ethernet 1/5
```

Syntax: `clear port security statistics all | ethernet <port>`

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Displaying port security information

You can display the following information about the MAC port security feature:

- The port security settings for an individual port or for all the ports on a specified module
- The secure MAC addresses configured on the device
- Port security statistics for an interface or for a module

Displaying port security settings

You can display the port security settings for an individual port or for all the ports on a specified module. For example, to display the port security settings for port 7/11, enter the following command.

```
Brocade#show port security ethernet 7/11
Port  Security Violation Shutdown-Time Age-Time  Max-MAC
-----
7/11 disabled shutdown 10 10 1
```

Syntax: `show port security ethernet <port>`

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

TABLE 304 Output from the `show port security ethernet` command

Field	Description
Port	The slot and port number of the interface.
Security	Whether the port security feature has been enabled on the interface.
Violation	The action to be undertaken when a security violation occurs, either “shutdown” or “restrict”.
Shutdown-Time	The number of seconds a port is shut down following a security violation, if the port is set to “shutdown” when a violation occurs.
Age-Time	The amount of time, in minutes, MAC addresses learned on the port will remain secure.
Max-MAC	The maximum number of secure MAC addresses that can be learned on the interface.

Displaying the secure MAC addresses

To list the secure MAC addresses configured on the device, enter the following command.

```
Brocade#show port security mac
Port Num-Addr Secure-Src-Addr Resource Age-Left Shutdown/Time-Left
-----
7/11 1 0050.da18.747c Local 10 no
```

Syntax: `show port security mac`

[Table 305](#) describes the output from the `show port security mac` command.

TABLE 305 Output from the `show port security mac` command

Field	Description
Port	The slot and port number of the interface.
Num-Addr	The number of MAC addresses secured on this interface.
Secure-Src-Addr	The secure MAC address.
Resource	Whether the address was secured using a local or global resource. Refer to “Local and global resources used for MAC port security” on page 1838 for more information.
Age-Left	The number of minutes the MAC address will remain secure.
Shutdown/Time-Left	Whether the interface has been shut down due to a security violation and the number of seconds before it is enabled again.

NOTE

For FCX and ICX switches, after every switchover or failover, the MAC “Age-Left” timer is reset to start since it is not synchronized between the master and the standby stack unit. This behavior is different on the FastIron SX devices where the “Age-Left” timer is not reset.

Displaying port security statistics

You can display port security statistics for an interface or for a module.

For example, to display port security statistics for interface 7/11, enter the following command.

```
Brocade#show port security statistics e 7/11
Port   Total-Addrs Maximum-Addrs Violation Shutdown/Time-Left
-----
7/11           1             1           0           no
```

Syntax: `show port security statistics <port>`

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

TABLE 306 Output from the `show port security statistics <port>` command

Field	Description
Port	The slot and port number of the interface.
Total-Addrs	The total number of secure MAC addresses on the interface.
Maximum-Addrs	The maximum number of secure MAC addresses on the interface.

TABLE 306 Output from the **show port security statistics <port>** command (Continued)

Field	Description
Violation	The number of security violations on the port.
Shutdown/Time-Left	Whether the port has been shut down due to a security violation and the number of seconds before it is enabled again.

For example, to display port security statistics for interface module 7, enter the **show port security statistics** command.

```
Brocade#show port security statistics 7
Module 7:
  Total ports: 0
  Total MAC address(es): 0
  Total violations: 0
  Total shutdown ports 0
```

Syntax: **show port security statistics <module>**

Table 307 describes the output from the **show port security statistics** *<module>* command.

TABLE 307 Output from the **show port security statistics** *<module>* command

Field	Description
Total ports	The number of ports on the module.
Total MAC address(es)	The total number of secure MAC addresses on the module.
Total violations	The number of security violations encountered on the module.
Total shutdown ports	The number of times that ports on the module shut down as a result of security violations.

Displaying restricted MAC addresses on a port

To display a list of restricted MAC addresses on a port, enter a command such as the following.

```
Brocade#show port security ethernet 1/5 restricted-macs
```

Syntax: **show port security ethernet** *<port>* **restricted-macs**

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Displaying port security information

Multi-Device Port Authentication

Table 308 lists individual Brocade switches and the multi-device port authentication features they support. These features are supported in the Layer 2, base Layer 3, edge Layer 3, and full Layer 3 software images, except where explicitly noted.

TABLE 308 Supported Multi-device port authentication (MDPA) features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
Multi-Device Port Authentication	Yes	Yes	Yes	Yes	Yes
Support for Multi-Device Port Authentication together with:					
• Dynamic VLAN assignment	Yes	Yes	Yes	Yes	Yes
• Dynamic ACLs	Yes	Yes	Yes	Yes	Yes
• 802.1X	Yes	Yes	Yes	Yes	Yes
• Dynamic ARP inspection with dynamic ACLs	Yes	No	No	No	Yes
• DHCP snooping with dynamic ACLs	Yes	No	No	No	Yes
• Denial of Service (DoS) attack protection	Yes	No	Yes	Yes	Yes
• Source guard protection	Yes	Yes	Yes	Yes	Yes
• ACL-per-port-per-VLAN	Yes	Yes	Yes	Yes	Yes
Automatic removal of Dynamic VLAN for MAC authenticated ports	Yes	No	No	No	Yes
Authenticating multiple MAC addresses on an interface	Yes	Yes	Yes	Yes	Yes
Authenticating clients that send tagged packets on non-member ports	Yes	No	No	No	No
Specifying the format of the MAC addresses sent to the RADIUS server	Yes	Yes	Yes	Yes	Yes
Specifying the authentication-failure action	Yes	Yes	Yes	Yes	Yes
Password override	Yes	Yes	Yes	Yes	Yes
Specifying the RADIUS timeout action	Yes	Yes	Yes	Yes	Yes
SNMP Traps	Yes	Yes	Yes	Yes	Yes
MAC Address Filters	Yes	Yes	Yes	Yes	Yes
Aging time for blocked MAC Addresses	Yes	Yes	Yes	Yes	Yes

NOTE

FCX devices do **not** support:

- multi-device authentication on dynamic (LACP) and static trunk ports
 - multi-device authentication and port security configured on the same port
 - multi-device authentication and lock-address configured on the same port
-

Multi-device port authentication is a way to configure a Brocade device to forward or block traffic from a MAC address based on information received from a RADIUS server.

How multi-device port authentication works

Multi-device port authentication is a way to configure a Brocade device to forward or block traffic from a MAC address based on information received from a RADIUS server.

The multi-device port authentication feature is a mechanism by which incoming traffic originating from a specific MAC address is switched or forwarded by the device only if the source MAC address is successfully authenticated by a RADIUS server. The MAC address itself is used as the username and password for RADIUS authentication; the user does not need to provide a specific username and password to gain access to the network. If RADIUS authentication for the MAC address is successful, traffic from the MAC address is forwarded in hardware.

If the RADIUS server cannot validate the user's MAC address, then it is considered an authentication failure, and a specified authentication-failure action can be taken. The default authentication-failure action is to drop traffic from the non-authenticated MAC address in hardware. You can also configure the device to move the port on which the non-authenticated MAC address was learned into a restricted or “guest” VLAN, which may have limited access to the network.

RADIUS authentication

The multi-device port authentication feature communicates with the RADIUS server to authenticate a newly found MAC address. The Brocade device supports multiple RADIUS servers; if communication with one of the RADIUS servers times out, the others are tried in sequential order. If a response from a RADIUS server is not received within a specified time (by default, 3 seconds) the RADIUS session times out, and the device retries the request up to three times. If no response is received, the next RADIUS server is chosen, and the request is sent for authentication.

The RADIUS server is configured with the usernames and passwords of authenticated users. For multi-device port authentication, the username and password is the MAC address itself; that is, the device uses the MAC address for both the username and the password in the request sent to the RADIUS server. For example, given a MAC address of 0007e90feaa1, the users file on the RADIUS server would be configured with a username and password both set to 0007e90feaa1. When traffic from this MAC address is encountered on a MAC-authentication-enabled interface, the device sends the RADIUS server an Access-Request message with 0007e90feaa1 as both the username and password. The format of the MAC address sent to the RADIUS server is configurable through the CLI.

The request for authentication from the RADIUS server is successful only if the username and password provided in the request matches an entry in the users database on the RADIUS server. When this happens, the RADIUS server returns an Access-Accept message back to the Brocade device. When the RADIUS server returns an Access-Accept message for a MAC address, that MAC address is considered authenticated, and traffic from the MAC address is forwarded normally by the Brocade device.

Authentication-failure actions

If the MAC address does not match the username and password of an entry in the users database on the RADIUS server, then the RADIUS server returns an Access-Reject message. When this happens, it is considered an authentication failure for the MAC address. When an authentication failure occurs, the Brocade device can either drop traffic from the MAC address in hardware (the default), or move the port on which the traffic was received to a restricted VLAN.

Supported RADIUS attributes

Brocade devices support the following RADIUS attributes for multi-device port authentication:

- Username (1) – RFC 2865
- NAS-IP-Address (4) – RFC 2865
- NAS-Port (5) – RFC 2865
- Service-Type (6) – RFC 2865
- FilterId (11) – RFC 2865
- Framed-MTU (12) – RFC 2865
- State (24) – RFC 2865
- Vendor-Specific (26) – RFC 2865
- Session-Timeout (27) – RFC 2865
- Termination-Action (29) – RFC 2865
- Calling-Station-ID (31) – RFC 2865
- NAS-Port-Type (61) – RFC 2865
- Tunnel-Type (64) – RFC 2868
- Tunnel-Medium-Type (65) – RFC 2868
- EAP Message (79) – RFC 2579
- Message-Authenticator (80) RFC 3579
- Tunnel-Private-Group-Id (81) – RFC 2868
- NAS-Port-id (87) – RFC 2869

Support for dynamic VLAN assignment

The Brocade multi-device port authentication feature supports **dynamic VLAN assignment**, where a port can be placed in one or more VLANs based on the MAC address learned on that interface. For details about this feature, refer to [“Configuring the RADIUS server to support dynamic VLAN assignment”](#) on page 1859.

Support for dynamic ACLs

The multi-device port authentication feature supports the assignment of a MAC address to a specific ACL, based on the MAC address learned on the interface. For details about this feature, refer to [“Dynamically applying IP ACLs to authenticated MAC addresses”](#) on page 1861.

Support for authenticating multiple MAC addresses on an interface

The multi-device port authentication feature allows multiple MAC addresses to be authenticated or denied authentication on each interface. The maximum number of MAC addresses that can be authenticated on each interface is limited only by the amount of system resources available on the Brocade device.

Support for dynamic ARP inspection with dynamic ACLs

NOTE

This feature is not supported on FWS and FCX devices.

Multi-device port authentication and Dynamic ARP Inspection (DAI) are supported in conjunction with dynamic ACLs. Support is available in the Layer 3 software images only.

DAI is supported together with multi-device port authentication as long as **ACL-per-port-per-vlan** is enabled. Otherwise, you do not need to perform any extra configuration steps to enable support with dynamic ACLs. When these features are enabled on the same port/VLAN, support is automatically enabled.

Support for DHCP snooping with dynamic ACLs

NOTE

This feature is not supported on FWS and FCX devices.

Multi-device port authentication and DHCP snooping are supported in conjunction with dynamic ACLs. Support is available in the Layer 3 software images only.

DHCP Snooping is supported together with multi-device port authentication as long as **ACL-per-port-per-vlan** is enabled. Otherwise, you do not need to perform any extra configuration steps to enable support with dynamic ACLs. When these features are enabled on the same port/VLAN, support is automatically enabled.

Support for source guard protection

The Brocade proprietary **Source Guard Protection** feature, a form of IP Source Guard, can be used in conjunction with multi-device port authentication. For details, refer to [“Enabling source guard protection”](#) on page 1864.

Multi-device port authentication and 802.1X security on the same port

On some Brocade devices, multi-device port authentication and 802.1X security can be configured on the same port, as long as the port is not a trunk port or an LACP port. When both of these features are enabled on the same port, multi-device port authentication is performed prior to 802.1X authentication. If multi-device port authentication is successful, 802.1X authentication may be performed, based on the configuration of a vendor-specific attribute (VSA) in the profile for the MAC address on the RADIUS server.

NOTE

When multi-device port authentication and 802.1X security are configured together on the same port, Brocade recommends that dynamic VLANs and dynamic ACLs are done at the multi-device port authentication level, and not at the 802.1X level.

When both features are configured on a port, a device connected to the port is authenticated as follows.

1. Multi-device port authentication is performed on the device to authenticate the device MAC address.
2. If multi-device port authentication is successful for the device, then the device checks whether the RADIUS server included the Foundry-802_1x-enable VSA (described in [Table 309](#)) in the Access-Accept message that authenticated the device.
3. If the Foundry-802_1x-enable VSA is not present in the Access-Accept message, or is present and set to 1, then 802.1X authentication is performed for the device.
4. If the Foundry-802_1x-enable VSA is present in the Access-Accept message, and is set to 0, then 802.1X authentication is skipped. The device is authenticated, and any dynamic VLANs specified in the Access-Accept message returned during multi-device port authentication are applied to the port.
5. If 802.1X authentication is performed on the device, and is successful, then dynamic VLANs or ACLs specified in the Access-Accept message returned during 802.1X authentication are applied to the port.

If multi-device port authentication fails for a device, then by default traffic from the device is either blocked in hardware, or the device is placed in a restricted VLAN. You can optionally configure the Brocade device to perform 802.1X authentication on a device when it fails multi-device port authentication. Refer to [“Example 2 – Creating a profile on the RADIUS server for each MAC address”](#) on page 1884 for a sample configuration where this is used.

Configuring Brocade-specific attributes on the RADIUS server

If the RADIUS authentication process is successful, the RADIUS server sends an Access-Accept message to the Brocade device, authenticating the device. The Access-Accept message can include Vendor-Specific Attributes (VSAs) that specify additional information about the device. If you are configuring multi-device port authentication and 802.1X authentication on the same port, then you can configure the Brocade VSAs listed in [Table 309](#) on the RADIUS server.

You add these Brocade vendor-specific attributes to your RADIUS server configuration, and configure the attributes in the individual or group profiles of the devices that will be authenticated. The Brocade Vendor-ID is 1991, with Vendor-Type 1.

TABLE 309 Brocade vendor-specific attributes for RADIUS

Attribute name	Attribute ID	Data type	Description
Foundry-802_1x-enable	6	integer	Specifies whether 802.1X authentication is performed when multi-device port authentication is successful for a device. This attribute can be set to one of the following: 0 - Do not perform 802.1X authentication on a device that passes multi-device port authentication. Set the attribute to zero for devices that do not support 802.1X authentication. 1 - Perform 802.1X authentication when a device passes multi-device port authentication. Set the attribute to one for devices that support 802.1X authentication.
Foundry-802_1x-valid	7	integer	Specifies whether the RADIUS record is valid only for multi-device port authentication, or for both multi-device port authentication and 802.1X authentication. This attribute can be set to one of the following: 0 - The RADIUS record is valid only for multi-device port authentication. Set this attribute to zero to prevent a user from using their MAC address as username and password for 802.1X authentication 1 - The RADIUS record is valid for both multi-device port authentication and 802.1X authentication.

If neither of these VSAs exist in a device profile on the RADIUS server, then by default the device is subject to multi-device port authentication (if configured), then 802.1X authentication (if configured). The RADIUS record can be used for both multi-device port authentication and 802.1X authentication.

Configuration examples are shown in [“Examples of multi-device port authentication and 802.1X authentication configuration on the same port”](#) on page 1882.

Multi-device port authentication configuration

Configuring multi-device port authentication on the Brocade device consists of the following tasks:

- Enabling multi-device port authentication globally and on individual interfaces
- Specifying the format of the MAC addresses sent to the RADIUS server (optional)
- Specifying the authentication-failure action (optional)
- Enabling and disabling SNMP traps for multi-device port authentication
- Defining MAC address filters (optional)
- Configuring dynamic VLAN assignment (optional)
- Dynamically Applying IP ACLs to authenticated MAC addresses
- Enabling denial of service attack protection (optional)
- Clearing authenticated MAC addresses (optional)
- Disabling aging for authenticated MAC addresses (optional)
- Configuring the hardware aging period for blocked MAC addresses
- Specifying the aging time for blocked MAC addresses (optional)

Enabling multi-device port authentication

To enable multi-device port authentication, you first enable the feature globally on the device. On some Brocade devices, you can then enable the feature on individual interfaces.

Globally enabling multi-device port authentication

To globally enable multi-device port authentication on the device, enter the following command.

```
Brocade(config)#mac-authentication enable
```

Syntax: [no] mac-authentication enable

Enabling multi-device port authentication on an interface

To enable multi-device port authentication on an individual interface, enter a command such as the following.

```
Brocade(config)#mac-authentication enable ethernet 3/1
```

Syntax: [no] mac-authentication enable <port> | all

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

The **all** option enables the feature on all interfaces at once.

You can enable the feature on an interface at the interface CONFIG level.

Example of enabling multi-device port authentication on an interface

```
Brocade(config)#interface e 3/1
Brocade(config-if-e1000-3/1)#mac-authentication enable
```

Syntax: [no] mac-authentication enable

You can also configure multi-device port authentication commands on a range of interfaces.

Example of enabling multi-device port authentication on a range of interfaces

```
Brocade(config)#int e 3/1 to 3/12
Brocade(config-mif-3/1-3/12)#mac-authentication enable
```

Specifying the format of the MAC addresses sent to the RADIUS server

When multi-device port authentication is configured, the Brocade device authenticates MAC addresses by sending username and password information to a RADIUS server. The username and password is the MAC address itself; that is, the device uses the MAC address for both the username and the password in the request sent to the RADIUS server.

By default, the MAC address is sent to the RADIUS server in the format xxxxxxxxxxxx. You can optionally configure the device to send the MAC address to the RADIUS server in the format xx-xx-xx-xx-xx-xx, or the format xxxx.xxxx.xxxx. To do this, enter a command such as the following.

```
Brocade(config)#mac-authentication auth-passwd-format xxxx.xxxx.xxxx
```

Syntax: [no] mac-authentication auth-passwd-format xxxx.xxxx.xxxx | xx-xx-xx-xx-xx-xx | xxxxxxxxxxxx

Specifying the authentication-failure action

When RADIUS authentication for a MAC address fails, you can configure the device to perform one of two actions:

- Drop traffic from the MAC address in hardware (the default)
- Move the port on which the traffic was received to a restricted VLAN

To configure the device to move the port to a restricted VLAN when multi-device port authentication fails, enter commands such as the following.

```
Brocade(config)#interface e 3/1
Brocade(config-if-e1000-3/1)#mac-authentication auth-fail-action restrict-vlan 100
```

Syntax: [no] mac-authentication auth-fail-action restrict-vlan [<vlan-id>]

If the ID for the restricted VLAN is not specified at the interface level, the global restricted VLAN ID applies for the interface.

To specify the VLAN ID of the restricted VLAN globally, enter the following command.

```
Brocade(config)#mac-authentication auth-fail-vlan-id 200
```

Syntax: [no] mac-authentication auth-fail-vlan-id <vlan-id>

The command above applies globally to all MAC-authentication-enabled interfaces.

Note that the restricted VLAN must already exist on the device. You cannot configure the restricted VLAN to be a non-existent VLAN. If the port is a tagged or dual-mode port, you cannot use a restricted VLAN as the authentication-failure action.

To configure the device to drop traffic from non-authenticated MAC addresses in hardware, enter commands such as the following.

```
Brocade(config)#interface e 3/1
Brocade(config-if-e1000-3/1)#mac-authentication auth-fail-action block-traffic
```

Syntax: [no] **mac-authentication auth-fail-action block-traffic**

Dropping traffic from non-authenticated MAC addresses is the default behavior when multi-device port authentication is enabled.

Generating traps for multi-device port authentication

You can enable and disable SNMP traps for multi-device port authentication. SNMP traps are enabled by default.

To enable SNMP traps for multi-device port authentication after they have been disabled, enter the following command.

```
Brocade(config)#snmp-server enable traps mac-authentication
```

Syntax: [no] **snmp-server enable traps mac-authentication**

Use the **no** form of the command to disable SNMP traps for multi-device port authentication.

Defining MAC address filters

You can specify MAC addresses that do not have to go through multi-device port authentication. These MAC addresses are considered pre-authenticated, and are not subject to RADIUS authentication. To do this, you can define MAC address filters that specify the MAC addresses to exclude from multi-device port authentication.

You should use a MAC address filter when the RADIUS server itself is connected to an interface where multi-device port authentication is enabled. If a MAC address filter is not defined for the MAC address of the RADIUS server and applied on the interface, the RADIUS authentication process would fail since the device would drop all packets from the RADIUS server itself.

For example, the following command defines a MAC address filter for address 0010.dc58.aca4.

```
Brocade(config)#mac-authentication mac-filter 1 0010.dc58.aca4
```

Syntax: [no] **mac-authentication mac-filter <filter>**

The following commands apply the MAC address filter on an interface so that address 0010.dc58.aca4 is excluded from multi-device port authentication.

```
Brocade(config)#interface e 3/1
Brocade(config-if-e1000-3/1)#mac-authentication apply-mac-auth-filter 1
```

Syntax: [no] **mac-authentication apply-mac-auth-filter <filter-id>**

Configuring dynamic VLAN assignment

An interface can be dynamically assigned to one or more VLANs based on the MAC address learned on that interface. When a MAC address is successfully authenticated, the RADIUS server sends the Brocade device a RADIUS Access-Accept message that allows the Brocade device to forward traffic from that MAC address. The RADIUS Access-Accept message can also contain attributes set for the MAC address in its access profile on the RADIUS server.

If one of the attributes in the Access-Accept message specifies one or more VLAN identifiers, and the VLAN is available on the Brocade device, the port is moved from its default VLAN to the specified VLAN.

To enable dynamic VLAN assignment for authenticated MAC addresses, you must add attributes to the profile for the MAC address on the RADIUS server, then enable dynamic VLAN assignment on multi-device port authentication-enabled interfaces. Refer to [“Configuring the RADIUS server to support dynamic VLAN assignment”](#) on page 1859 for a list of the attributes that must be set on the RADIUS server.

To enable dynamic VLAN assignment on a multi-device port authentication-enabled interface, enter commands such as the following.

```
Brocade(config)#interface e 3/1
Brocade(config-if-e1000-3/1)#mac-authentication enable-dynamic-vlan
```

Syntax: [no] mac-authentication enable-dynamic-vlan

Configuring a port to remain in the restricted VLAN after a successful authentication attempt

If a previous authentication attempt for a MAC address failed, and as a result the port was placed in the restricted VLAN, but a subsequent authentication attempt was successful, the RADIUS Access-Accept message may specify a VLAN for the port. By default, the Brocade device moves the port out of the restricted VLAN and into the RADIUS-specified VLAN. You can optionally configure the device to leave the port in the restricted VLAN. To do this, enter the following command.

```
Brocade(config-if-e1000-3/1)#mac-authentication no-override-restrict-vlan
```

When the above command is applied, if the RADIUS-specified VLAN configuration is tagged (e.g., T:1024) and the VLAN is valid, then the port is placed in the RADIUS-specified VLAN as a tagged port and left in the restricted VLAN. If the RADIUS-specified VLAN configuration is untagged (e.g., U:1024), the configuration from the RADIUS server is ignored, and the port is left in the restricted VLAN.

Syntax: [no] mac-authentication no-override-restrict-vlan

Configuration notes for configuring a port to remain in the restricted VLAN

- If you configure dynamic VLAN assignment on a multi-device port authentication enabled interface, and the Access-Accept message returned by the RADIUS server contains a Tunnel-Type and Tunnel-Medium-Type, but does not contain a Tunnel-Private-Group-ID attribute, then it is considered an authentication failure, and the configured authentication failure action is performed for the MAC address.

- If the `<vlan-name>` string does not match either the name or the ID of a VLAN configured on the device, then it is considered an authentication failure, and the configured authentication failure action is performed for the MAC address.
- For tagged or dual-mode ports, if the VLAN ID provided by the RADIUS server does not match the VLAN ID in the tagged packet that contains the authenticated MAC address as its source address, then it is considered an authentication failure, and the configured authentication failure action is performed for the MAC address.
- If an untagged port had previously been assigned to a VLAN through dynamic VLAN assignment, and then another MAC address is authenticated on the same port, but the RADIUS Access-Accept message for the second MAC address specifies a different VLAN, then it is considered an authentication failure for the second MAC address, and the configured authentication failure action is performed. Note that this applies only if the first MAC address has not yet aged out. If the first MAC address has aged out, then dynamic VLAN assignment would work as expected for the second MAC address.
- For dual mode ports, if the RADIUS server returns T:<vlan-name>, the traffic will still be forwarded in the statically assigned PVID. If the RADIUS server returns U:<vlan-name>, the traffic will not be forwarded in the statically assigned PVID.

Configuring the RADIUS server to support dynamic VLAN assignment

To specify VLAN identifiers on the RADIUS server, add the following attributes to the profile for the MAC address on the RADIUS server, then enable dynamic VLAN assignment on multi-device port authentication-enabled interfaces.

Attribute name	Type	Value
Tunnel-Type	064	13 (decimal) – VLAN
Tunnel-Medium-Type	065	6 (decimal) – 802
Tunnel-Private-Group-ID	081	<vlan-name> (string) The <vlan-name> value can specify either the name or the number of one or more VLANs configured on the Brocade device.

For information about the attributes, refer to [“Dynamic multiple VLAN assignment for 802.1X ports”](#) on page 1803.

Also, refer to the example configuration of [“Multi-device port authentication with dynamic VLAN assignment”](#) on page 1879.

Enabling dynamic VLAN support for tagged packets on non-member VLAN ports

NOTE

This feature is not supported on FWS and FCX devices.

By default, the Brocade device drops tagged packets that are received on non-member VLAN ports. This process is called **ingress filtering**. Since the MAC address of the packets are not learned, authentication does not take place.

The Brocade device can authenticate clients that send tagged packets on non-member VLAN ports. This enables the Brocade device to add the VLAN dynamically. To enable support, enter the following command at the Interface level of the CLI.

```
Brocade(config)#interface e 3/1
Brocade(config-if-e1000-3/1)#mac-authentication disable-ingress-filtering
```

If the client MAC address is successfully authenticated and the correct VLAN attribute is sent by the RADIUS server, the MAC address will be successfully authenticated on the VLAN.

Syntax: `mac-authentication disable-ingress-filtering`

Configuration notes and limitations:

- This feature works in conjunction with multi-device port authentication with dynamic VLAN assignment only. If this feature is not enabled, authentication works as in [“Example 2 – multi-device port authentication with dynamic VLAN assignment”](#) on page 1881 .
- The port on which ingress filtering is disabled must be tagged to a VLAN.
- If a host sends both tagged and untagged traffic, and ingress filtering is disabled on the port, the port must be configured as a dual-mode port.

Specifying to which VLAN a port is moved after its RADIUS-specified VLAN assignment expires

When a port is dynamically assigned to a VLAN through the authentication of a MAC address, and the MAC session for that address is deleted on the Brocade device, then by default the port is removed from its RADIUS-assigned VLAN and placed back in the VLAN where it was originally assigned.

A port can be removed from its RADIUS-assigned VLAN when any of the following occur:

- The link goes down for the port
- The MAC session is manually deleted with the `mac-authentication clear-mac-session` command
- The MAC address that caused the port to be dynamically assigned to a VLAN ages out

For example, say port 1/1 is currently in VLAN 100, to which it was assigned when MAC address 0007.eaa1.e90f was authenticated by a RADIUS server. The port was originally configured to be in VLAN 111. If the MAC session for address 0007.eaa1.e90f is deleted, then port 1/1 is moved from VLAN 100 back into VLAN 111.

You can optionally specify an alternate VLAN to which to move the port when the MAC session for the address is deleted. For example, to place the port in the restricted VLAN, enter commands such as the following.

```
Brocade(config)#interface e 3/1
Brocade(config-if-e1000-3/1)#mac-auth move-back-to-old-vlan port-restrict-vlan
```

Syntax: `[no] mac-authentication move-back-to-old-vlan port-restrict-vlan | port-configured-vlan | system-default-vlan`

The **port-configured-vlan** keyword removes the port from its RADIUS-assigned VLAN and places it back in the VLAN where it was originally assigned. This is the default.

The **port-restrict-vlan** keyword removes the port from its RADIUS-assigned VLAN and places it in the restricted VLAN.

The **system-default-vlan** keyword removes the port from its RADIUS-assigned VLAN and places it in the DEFAULT-VLAN.

NOTE

When a MAC session is deleted, if the port is moved back to a VLAN that is different than the running-config file, the system will update the running-config file to reflect the changes. This will occur even if **mac-authentication save-dynamicvlan-to-config** is not configured.

Automatic removal of dynamic VLAN assignments for MAC authenticated ports

NOTE

This feature is not supported on FWS and FCX devices.

By default, the Brocade device removes any association between a port and a dynamically-assigned VLAN when all authenticated MAC sessions for that tagged or untagged VLAN have expired on the port. Thus, RADIUS-specified VLAN assignments are not saved to the device running-config file. When the **show run** command is issued during a session, dynamically-assigned VLANs are not displayed, although they can be displayed with the **show vlan**, **show auth-mac-addresses detail**, and **show auth-mac-addresses authorized-mac** commands.

You can optionally configure the Brocade device to save the RADIUS-specified VLAN assignments to the device's running-config file. Refer to [“Saving dynamic VLAN assignments to the running-config file”](#), next.

Saving dynamic VLAN assignments to the running-config file

By default, dynamic VLAN assignments are not saved to the running-config file of the Brocade device. However, you can configure the device to do so by entering the following command.

```
Brocade(config)#mac-authentication save-dynamicvlan-to-config
```

When the above command is applied, dynamic VLAN assignments are saved to the running-config file and are displayed when the **show run** command is issued. Dynamic VLAN assignments can also be displayed with the **show vlan**, **show auth-mac-addresses detail**, and **show auth-mac-addresses authorized-mac** commands.

Syntax: [no] **mac-authentication save-dynamicvlan-to-config**

Dynamically applying IP ACLs to authenticated MAC addresses

The Brocade multi-device port authentication implementation supports the assignment of a MAC address to a specific ACL, based on the MAC address learned on the interface.

When a MAC address is successfully authenticated, the RADIUS server sends the Brocade device a RADIUS Access-Accept message that allows the Brocade device to forward traffic from that MAC address. The RADIUS Access-Accept message can also contain, among other attributes, the Filter-ID (type 11) attribute for the MAC address. When the Access-Accept message containing the Filter-ID (type 11) attribute is received by the Brocade device, it will use the information in these attributes to apply an IP ACL on a per-MAC (per user) basis.

The dynamic IP ACL is active as long as the client is connected to the network. When the client disconnects from the network, the IP ACL is no longer applied to the port. If an IP ACL had been applied to the port prior to multi-device port authentication; it will be re-applied to the port.

NOTE

A dynamic IP ACL will take precedence over an IP ACL that is bound to a port (port ACL). When a client authenticates with a dynamic IP ACL, the port ACL will not be applied. Also, future clients on the same port will authenticate with a dynamic IP ACL or no IP ACL. If no clients on the port use dynamic ACL, then the port ACL will be applied to all traffic.

The Brocade device uses information in the Filter ID to apply an IP ACL on a per-user basis. The Filter-ID attribute can specify the number of an existing IP ACL configured on the Brocade device. If the Filter-ID is an ACL number, the specified IP ACL is applied on a per-user basis.

Multi-device port authentication with dynamic IP ACLs and ACL-per-port-per-VLAN

The following features are supported:

- FastIron X Series devices support multi-device port authentication and dynamic ACLs together with **ACL-per-port-per-vlan** (ACL filtering based on VLAN membership or VE port membership).
- Multi-device port authentication and dynamic ACLs are supported on tagged, dual-mode, and untagged ports, with or without virtual Interfaces.

Support is automatically enabled when all of the required conditions are met.

The following describes the conditions and feature limitations:

- On Layer 3 router code, dynamic IP ACLs are allowed on physical ports when **ACL-per-port-per-vlan** is enabled.
- On Layer 3 router code, dynamic IP ACLs are allowed on tagged and dual-mode ports when **ACL-per-port-per-vlan** is enabled. If **ACL-per-port-per-vlan** is not enabled, dynamic IP ACLs are not allowed on tagged or dual-mode ports.
- Dynamic IP ACLs can be added to tagged/untagged ports in a VLAN with or without a VE, as long as the tagged/untagged ports do not have configured ACLs assigned to them. The following shows some example scenarios where dynamic IP ACLs would not apply:
 - A port is a tagged/untagged member of VLAN 20, VLAN 20 includes VE 20, and an ACL is bound to VE 20.
 - A port is a tagged/untagged member of VLAN 20, VLAN 20 includes VE 20, and a per-port-per-vlan ACL is bound to VE 20 and to a subset of ports in VE 20

In the above scenarios, dynamic IP ACL assignment would not apply in either instance, because a configured ACL is bound to VE 20 on the port. Consequently, the MAC session would fail.

Configuration considerations and guidelines for multi-device port authentication

- On FastIron X Series devices, dynamic ARP inspection (DAI) and DHCP Snooping are supported together with dynamic ACLs.
- Dynamic IP ACLs with multi-device port authentication are supported. Dynamic MAC address filters with multi-device port authentication are not supported.
- In the Layer 2 switch code, dynamic IP ACLs are not supported when **ACL-per-port-per-vlan** is enabled on a global-basis.

- The RADIUS Filter ID (type 11) attribute is supported. The Vendor-Specific (type 26) attribute is not supported.
- The dynamic ACL must be an extended ACL. Standard ACLs are not supported.
- Multi-device port authentication and 802.1x can be used together on the same port. However, Brocade does not recommend the use of multi-device port authentication and 802.1X with dynamic ACLs together on the same port. If a single supplicant requires both 802.1x and multi-device port authentication, and if both 802.1x and multi-device port authentication try to install different dynamic ACLs for the same supplicant, the supplicant will fail authentication.
- Dynamically assigned IP ACLs are subject to the same configuration restrictions as non-dynamically assigned IP ACLs. One caveat is that ports with VE interfaces cannot have assigned user-defined ACLs. For example, a user-defined ACL bound to a VE or a port on a VE is not allowed. There are no restrictions on ports that do not have VE interfaces.
- Dynamic ACL filters are supported only for the inbound direction. Dynamic outbound ACL filters are not supported.
- Dynamic ACL assignment with multi-device port authentication is not supported in conjunction with any of the following features:
 - IP source guard
 - Rate limiting
 - Protection against ICMP or TCP Denial-of-Service (DoS) attacks
 - Policy-based routing
 - 802.1X dynamic filter

Configuring the RADIUS server to support dynamic IP ACLs

When a port is authenticated using multi-device port authentication, an IP ACL filter that exists in the running-config file on the Brocade device can be dynamically applied to the port. To do this, you configure the Filter-ID (type 11) attribute on the RADIUS server. The Filter-ID attribute specifies the name or number of the Brocade IP ACL.

The following is the syntax for configuring the Filter-ID attribute on the RADIUS server to refer to a Brocade IP ACL.

Value	Description
ip.<number>.in ¹	Applies the specified numbered ACL to the authenticated port in the inbound direction.
ip.<name>.in ^{1,2}	Applies the specified named ACL to the authenticated port in the inbound direction.

1. The ACL must be an extended ACL. Standard ACLs are not supported.
2. The <name> in the Filter ID attribute is case-sensitive

The following table lists examples of values you can assign to the Filter-ID attribute on the RADIUS server to refer to IP ACLs configured on a Brocade device.

Possible values for the filter ID attribute on the RADIUS server	ACLs configured on the Brocade device
ip.102.in	access-list 102 permit ip 36.0.0.0 0.255.255.255 any
ip.fdry_filter.in	ip access-list standard fdry_filter permit host 36.48.0.3

Enabling denial of service attack protection

NOTE

This feature is not supported on FWS devices.

The Brocade device does not start forwarding traffic from an authenticated MAC address in hardware until the RADIUS server authenticates the MAC address; traffic from the non-authenticated MAC addresses is sent to the CPU. A denial of service (DoS) attack could be launched against the device where a high volume of new source MAC addresses is sent to the device, causing the CPU to be overwhelmed with performing RADIUS authentication for these MAC addresses. In addition, the high CPU usage in such an attack could prevent the RADIUS response from reaching the CPU in time, causing the device to make additional authentication attempts.

To limit the susceptibility of the Brocade device to such attacks, you can configure the device to use multiple RADIUS servers, which can share the load when there are a large number of MAC addresses that need to be authenticated. The Brocade device can run a maximum of 10 RADIUS clients per server and will attempt to authenticate with a new RADIUS server if current one times out.

In addition, you can configure the Brocade device to limit the rate of authentication attempts sent to the RADIUS server. When the multi-device port authentication feature is enabled, it keeps track of the number of RADIUS authentication attempts made per second. When you also enable the DoS protection feature, if the number of RADIUS authentication attempts for MAC addresses learned on an interface per second exceeds a configurable rate (by default 512 authentication attempts per second), the device considers this a possible DoS attack and disables the port. You must then manually re-enable the port.

The DoS protection feature is disabled by default. To enable it on an interface, enter commands such as the following.

```
Brocade(config)#interface e 3/1
Brocade(config-if-e1000-3/1)#mac-authentication dos-protection enable
```

To specify a maximum rate for RADIUS authentication attempts, enter commands such as the following.

```
Brocade(config)#interface e 3/1
Brocade(config-if-e1000-3/1)#mac-authentication dos-protection mac-limit 256
```

Syntax: [no] **mac-authentication dos-protection mac-limit** <number>

You can specify a rate from 1 – 65535 authentication attempts per second. The default is a rate of 512 authentication attempts per second.

Enabling source guard protection

Source Guard Protection is a form of IP Source Guard used in conjunction with multi-device port authentication. When Source Guard Protection is enabled, IP traffic is blocked until the system learns the IP address. Once the IP address is validated, traffic with that source address is permitted.

NOTE

Source Guard Protection is supported together with multi-device port authentication as long as **ACL-per-port-per-vlan** is enabled.

When a new MAC session begins on a port that has Source Guard Protection enabled, the session will either apply a dynamically created Source Guard ACL entry, or it will use the dynamic IP ACL assigned by the RADIUS server. If a dynamic IP ACL is not assigned, the session will use the Source Guard ACL entry. The Source Guard ACL entry is **permit ip <secure-ip> any**, where <secure-ip> is obtained from the ARP Inspection table or from the DHCP Secure table. The DHCP Secure table is comprised of DHCP Snooping and Static ARP Inspection entries.

The Source Guard ACL permit entry is added to the hardware table after all of the following events occur:

- The MAC address is authenticated
- The IP address is learned
- The MAC-to-IP mapping is checked against the Static ARP Inspection table or the DHCP Secure table.

The Source Guard ACL entry is not written to the running configuration file. However, you can view the configuration using the **show auth-mac-addresses authorized-mac ip-addr**. Refer to [“Viewing the assigned ACL for ports on which source guard protection is enabled”](#) in the following section.

NOTE

The secure MAC-to-IP mapping is assigned at the time of authentication and remains in effect as long as the MAC session is active. If the DHCP Secure table is updated after the session is authenticated and while the session is still active, it does not affect the existing MAC session.

The Source Guard ACL permit entry is removed when the MAC session expires or is cleared.

To enable Source Guard Protection on a port on which multi-device port authentication is enabled, enter the following command at the Interface level of the CLI.

```
FastIron(config)#int e 1/4
FastIron(config-if-e1000-1/4)#mac-authentication source-guard-protection enable
```

Syntax: [no] **mac-authentication source-guard-protection enable**

Enter the **no** form of the command to disable SG protection.

Viewing the assigned ACL for ports on which source guard protection is enabled

Use the following command to view whether a Source Guard ACL or dynamic ACL is applied to ports on which Source Guard Protection is enabled.

```
Brocade(config)#show auth-mac-addresses authorized-mac ip-addr
```

MAC Address	SourceIp	Port	Vlan	Auth	Age	ACL	dot1x
00A1.0010.2000	200.1.17.5	6/12	171	Yes	Dis	SG	Ena
00A1.0010.2001	200.1.17.6	6/13	171	Yes	Dis	103	Ena

In the above output, for port 6/12, Source Guard Protection is enabled and the Source Guard ACL is applied to the MAC session, as indicated by **SG** in the **ACL** column. For port 6/13, Source Guard Protection is also enabled, but in this instance, a dynamic ACL (103) is applied to the MAC session.

Clearing authenticated MAC addresses

The Brocade device maintains an internal table of the authenticated MAC addresses (viewable with the **show authenticated-mac-address** command). You can clear the contents of the authenticated MAC address table either entirely, or just for the entries learned on a specified interface. In addition, you can clear the MAC session for an address learned on a specific interface.

To clear the entire contents of the authenticated MAC address table, enter the **clear auth-mac-table** command.

```
Brocade#clear auth-mac-table
```

Syntax: clear auth-mac-table

To clear the authenticated MAC address table of entries learned on a specified interface, enter a command such as the following.

```
Brocade#clear auth-mac-table e 3/1
```

Syntax: clear auth-mac-table ethernet <port>

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

To clear the MAC session for an address learned on a specific interface, enter commands such as the following.

```
Brocade(config)#interface e 3/1
Brocade(config-if-e1000-3/1)#mac-authentication clear-mac-session 00e0.1234.abd4
```

Syntax: mac-authentication clear-mac-session <mac-address>

This command removes the Layer 2 CAM entry created for the specified MAC address. If the Brocade device receives traffic from the MAC address again, the MAC address is authenticated again.

NOTE

In a configuration with multi-device port authentication and 802.1X authentication on the same port, the **mac-authentication clear-mac-session** command will clear the MAC session, as well as its respective 802.1X session, if it exists.

Disabling aging for authenticated MAC addresses

MAC addresses that have been authenticated or denied by a RADIUS server are aged out if no traffic is received from the MAC address for a certain period of time:

- Authenticated MAC addresses or non-authenticated MAC addresses that have been placed in the restricted VLAN are aged out if no traffic is received from the MAC address over the device normal MAC aging interval.
- Non-authenticated MAC addresses that are blocked by the device are aged out if no traffic is received from the address over a fixed hardware aging period (70 seconds), plus a configurable software aging period. (Refer to the next section for more information on configuring the software aging period).

You can optionally disable aging for MAC addresses subject to authentication, either for all MAC addresses or for those learned on a specified interface.

Globally disabling aging of MAC addresses

On most devices, you can disable aging for all MAC addresses on all interfaces where multi-device port authentication has been enabled by entering the **mac-authentication disable-aging** command.

```
Brocade(config)#mac-authentication disable-aging
```

Syntax: mac-authentication disable-aging

Enter the command at the global or interface configuration level.

The **denied-only** parameter prevents denied sessions from being aged out, but ages out permitted sessions.

The **permitted-only** parameter prevents permitted (authenticated and restricted) sessions from being aged out and ages denied sessions.

Disabling the aging of MAC addresses on interfaces

To disable aging for all MAC addresses subject to authentication on a specific interface where multi-device port authentication has been enabled, enter the command at the interface level.

Example

```
Brocade(config)#interface e 3/1
Brocade(config-if-e1000-3/1)#mac-authentication disable-aging
```

Syntax: [no] mac-authentication disable-aging

Changing the hardware aging period for blocked MAC addresses

When the Brocade device is configured to drop traffic from non-authenticated MAC addresses, traffic from the blocked MAC addresses is dropped in hardware, without being sent to the CPU. A Layer 2 hardware entry is created that drops traffic from the MAC address in hardware. If no traffic is received from the MAC address for a certain amount of time, this Layer 2 hardware entry is aged out. If traffic is subsequently received from the MAC address, then an attempt can be made to authenticate the MAC address again.

Aging of the Layer 2 hardware entry for a blocked MAC address occurs in two phases, known as hardware aging and software aging.

On FastIron devices, the hardware aging period for blocked MAC addresses is fixed at 70 seconds and is non-configurable. (The hardware aging time for non-blocked MAC addresses is the length of time specified with the **mac-age** command.) The software aging period for blocked MAC addresses is configurable through the CLI, with the **mac-authentication max-age** command. Once the hardware aging period ends, the software aging period begins. When the software aging period ends, the blocked MAC address ages out, and can be authenticated again if the Brocade device receives traffic from the MAC address.

On FastIron X Series devices, the hardware aging period for blocked MAC addresses is not fixed at 70 seconds. The hardware aging period for blocked MAC addresses is equal to the length of time specified with the **mac-age** command. As on FastIron devices, once the hardware aging period ends, the software aging period begins. When the software aging period ends, the blocked MAC address ages out, and can be authenticated again if the device receives traffic from the MAC address.

To change the hardware aging period for blocked MAC addresses, enter a command such as the following.

```
Brocade(config)#mac-authentication hw-deny-age 10
```

Syntax: [no] **mac-authentication hw-deny-age** <num>

The <num> parameter is a value from 1 to 65535 seconds. The default is 70 seconds.

Specifying the aging time for blocked MAC addresses

When the Brocade device is configured to drop traffic from non-authenticated MAC addresses, traffic from the blocked MAC addresses is dropped in hardware, without being sent to the CPU. A Layer 2 CAM entry is created that drops traffic from the blocked MAC address in hardware. If no traffic is received from the blocked MAC address for a certain amount of time, this Layer 2 CAM entry is aged out. If traffic is subsequently received from the MAC address, then an attempt can be made to authenticate the MAC address again.

Aging of the Layer 2 CAM entry for a blocked MAC address occurs in two phases, known as **hardware aging** and **software aging**. The hardware aging period is fixed at 70 seconds and is non-configurable. The software aging time is configurable through the CLI.

Once the Brocade device stops receiving traffic from a blocked MAC address, the hardware aging begins and lasts for a fixed period of time. After the hardware aging period ends, the software aging period begins. The software aging period lasts for a configurable amount of time (by default 120 seconds). After the software aging period ends, the blocked MAC address ages out, and can be authenticated again if the Brocade device receives traffic from the MAC address.

To change the length of the software aging period for blocked MAC addresses, enter a command such as the following.

```
Brocade(config)#mac-authentication max-age 180
```

Syntax: [no] **mac-authentication max-age** <seconds>

You can specify from 1 – 65535 seconds. The default is 120 seconds.

Specifying the RADIUS timeout action

A RADIUS timeout occurs when the Brocade device does not receive a response from a RADIUS server within a specified time limit and after a certain number of retries. The time limit and number of retries can be manually configured using the CLI commands **radius-server timeout** and **radius-server retransmit**, respectively. If the parameters are not manually configured, the Brocade device applies the default value of three seconds with a maximum of three retries.

You can better control port behavior when a RADIUS timeout occurs by configuring a port on the Brocade device to automatically pass or fail user authentication. A **pass** essentially bypasses the authentication process and permits user access to the network. A **fail** bypasses the authentication process and blocks user access to the network, unless restrict-vlan is configured, in which case, the user is placed into a VLAN with restricted or limited access. By default, the Brocade device will reset the authentication process and retry to authenticate the user.

Specify the RADIUS timeout action at the Interface level of the CLI.

Permit User access to the network after a RADIUS timeout

To set the RADIUS timeout behavior to bypass multi-device port authentication and *permit* user access to the network, enter commands such as the following.

```
Brocade(config)#interface ethernet 1/3
Brocade(config-if-e100-1/3)#mac-authentication auth-timeout-action success
```

Syntax: [no] mac-authentication auth-timeout-action success

Once the *success* timeout action is enabled, use the *no* form of the command to reset the RADIUS timeout behavior to *retry*.

Deny User access to the network after a RADIUS timeout

To set the RADIUS timeout behavior to bypass multi-device port authentication and block user access to the network, enter commands such as the following.

```
Brocade(config)#interface ethernet 1/3
Brocade(config-if-e100-1/3)#mac-authentication auth-timeout-action failure
```

Syntax: [no] mac-authentication auth-timeout-action failure

Once the *failure* timeout action is enabled, use the **no** form of the command to reset the RADIUS timeout behavior to *retry*.

NOTE

If **restrict-vlan** is configured along with **auth-timeout-action failure**, the user will be placed into a VLAN with restricted or limited access. Refer to [“Allow user access to a restricted VLAN after a RADIUS timeout”](#) on page 1869.

Allow user access to a restricted VLAN after a RADIUS timeout

To set the RADIUS timeout behavior to bypass multi-device port authentication and place the user in a VLAN with restricted or limited access, enter commands such as the following.

```
Brocade(config)#interface ethernet 1/3
Brocade(config-if-e100-1/3)#mac-authentication auth-fail-action restrict-vlan 100
Brocade(config-if-e100-1/3)#mac-authentication auth-timeout-action failure
```

Syntax: [no] mac-authentication auth-fail-action restrict-vlan [<vlan-id>]

Syntax: [no] mac-authentication auth-timeout-action failure

Multi-device port authentication password override

The multi-device port authentication feature communicates with the RADIUS server to authenticate a newly found MAC address. The RADIUS server is configured with the usernames and passwords of authenticated users. For multi-device port authentication, the username and password is the MAC address itself; that is, the device uses the MAC address for both the username and the password in the request sent to the RADIUS server. For example, given a MAC address of 0007e90feaa1, the users file on the RADIUS server would be configured with a username and password both set to 0007e90feaa1. When traffic from this MAC address is encountered on a MAC-authentication-enabled interface, the device sends the RADIUS server an Access-Request message with 0007e90feaa1 as both the username and password.

The MAC address is the *default* password for multi-device port authentication, and you can optionally configure the device to use a different password. Note that the MAC address is still the username and cannot be changed.

To change the password for multi-device port authentication, enter a command such as the following at the GLOBAL Config Level of the CLI.

```
Brocade(config)#mac-authentication password-override
```

Syntax: [no] **mac-authentication password-override** <password>

where <password> can have up to 32 alphanumeric characters, but cannot include blank spaces.

Limiting the number of authenticated MAC addresses

You cannot enable MAC port security on the same port that has multi-device port authentication enabled. To simulate the function of MAC port security, you can enter a command such as the following.

```
Brocade(config-if-e1000-2)#mac-authentication max-accepted-session 5
```

Syntax: [no] **mac-authentication max-accepted-session** <session-number>

This command limits the number of successfully authenticated MAC addresses. Enter a value from 1 - 250 for session-number

Displaying multi-device port authentication information

You can display the following information about the multi-device port authentication configuration:

- Information about authenticated MAC addresses
- Information about the multi-device port authentication configuration
- Authentication Information for a specific MAC address or port
- Multi-device port authentication settings and authenticated MAC addresses for each port where the multi-device port authentication feature is enabled
- The MAC addresses that have been successfully authenticated
- The MAC addresses for which authentication was not successful

Displaying authenticated MAC address information

To display information about authenticated MAC addresses on the ports where the multi-device port authentication feature is enabled, enter the **show auth-mac address** command.

```
Brocade#show auth-mac-address
```

Port	Vlan	Accepted MACs	Rejected MACs	Attempted-MACs
1/18	100	1	100	0
1/20	40	0	0	0
1/22	100	0	0	0
4/5	30	0	0	0

Syntax: **show auth-mac-address**

The following table describes the information displayed by the **show auth-mac-address** command.

TABLE 310 Output from the **show authenticated-mac-address** command

Field	Description
Port	The port number where the multi-device port authentication feature is enabled.
Vlan	The VLAN to which the port has been assigned.
Accepted MACs	The number of MAC addresses that have been successfully authenticated
Rejected MACs	The number of MAC addresses for which authentication has failed.
Attempted-MACs	The rate at which authentication attempts are made for MAC addresses.

Displaying multi-device port authentication configuration information

To display information about the multi-device port authentication configuration, enter the **show auth-mac-address configuration** command.

```
Brocade#show auth-mac-address configuration
```

```
Feature enabled           : Yes
Number of Ports enabled   : 4
```

Port	Fail-Action	Fail-vlan	Dyn-vlan	MAC-filter
1/18	Block Traffic	1	No	No
1/20	Block Traffic	1	No	No
1/22	Block Traffic	1	No	Yes
4/5	Block Traffic	1	No	No

Syntax: **show auth-mac-address configuration**

The following table describes the output from the **show auth-mac-address configuration** command.

TABLE 311 Output from the **show authenticated-mac-address** configuration command

Field	Description
Feature enabled	Whether multi-device port authentication is enabled on the Brocade device.
Number of Ports enabled	The number of ports on which the multi-device port authentication feature is enabled.
Port	Information for each multi-device port authentication-enabled port.
Fail-Action	What happens to traffic from a MAC address for which RADIUS authentication has failed either block the traffic or assign the MAC address to a restricted VLAN.
Fail-vlan	The restricted VLAN to which non-authenticated MAC addresses are assigned, if the Fail-Action is to assign the MAC address to a restricted VLAN.
Dyn-vlan	Whether RADIUS dynamic VLAN assignment is enabled for the port.
MAC-filter	Whether a MAC address filter has been applied to specify pre-authenticated MAC addresses.

Displaying multi-device port authentication information for a specific MAC address or port

To display authentication information for a specific MAC address or port, enter a command such as the following.

```
Brocade#show auth-mac-address 0007.e90f.eaa1
-----
MAC/IP Address                Port      Vlan  Authenticated Time   Age  CAM
                                Index
-----
0007.e90f.eaa1 : 25.25.25.25   1/18     100   Yes    00d01h10m06s 0    N/A
```

Syntax: **show auth-mac-address** <mac-address> | <ip-addr> | <port>

The <ip-addr> variable lists the MAC address associated with the specified IP address.

The <slotnum> variable is required on chassis devices.

The <port> variable is a valid port number. Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

The following table describes the information displayed by the **show authenticated-mac-address** command for a specified MAC address or port.

TABLE 312 Output from the **show authenticated-mac-address <address>** command

Field	Description
MAC/IP Address	The MAC address for which information is displayed. If the packet for which multi-device port authentication was performed also contained an IP address, then the IP address is displayed as well.
Port	The port on which the MAC address was learned.
Vlan	The VLAN to which the MAC address was assigned.
Authenticated	Whether the MAC address was authenticated.
Time	The time at which the MAC address was authenticated. If the clock is set on the Brocade device, then the actual date and time are displayed. If the clock has not been set, then the time is displayed relative to when the device was last restarted.
Age	The age of the MAC address entry in the authenticated MAC address list.
CAM Index	If the MAC address is blocked, this is the index entry for the Layer 2 CAM entry created for this MAC address. If the MAC address is not blocked, either through successful authentication or through being placed in the restricted VLAN, then "N/A" is displayed. If the hardware aging period has expired, then "ffff" is displayed for the MAC address during the software aging period.

Displaying the authenticated MAC addresses

To display the MAC addresses that have been successfully authenticated, enter the **show auth-mac-addresses authorized-mac** command.

The following example output is from a FastIron X Series device. The display output on your device may differ, depending on the software version running on the device.

```
Brocade#show auth-mac-addresses authorized-mac
```

```
-----
MAC Address      Port      Vlan  Authenticated Time      Age      dot1x
-----
0030.4874.3181   15/23     101   Yes  00d01h03m17s  Ena      Ena
000f.ed00.0001   18/1      87    Yes  00d01h03m17s  Ena      Ena
000f.ed00.012d   18/1      87    Yes  00d01h03m17s  Ena      Ena
000f.ed00.0065   18/1      87    Yes  00d01h03m17s  Ena      Ena
000f.ed00.0191   18/1      87    Yes  00d01h03m17s  Ena      Ena
000f.ed00.01f5   18/1      87    Yes  00d01h03m17s  Ena      Ena
-----
```

Syntax: **show auth-mac-addresses authorized-mac**

Displaying the non-authenticated MAC addresses

To display the MAC addresses for which authentication was not successful, enter the **show auth-mac-addresses unauthorized-mac** command

```
Brocade#show auth-mac-addresses unauthorized-mac
```

```
-----
MAC Address      Port      Vlan  Authenticated Time   Age  dot1x
-----
000f.ed00.0321   18/1      87    No    00d01h03m17s  H44  Ena
000f.ed00.0259   18/1      87    No    00d01h03m17s  H44  Ena
000f.ed00.0385   18/1      87    No    00d01h03m17s  H44  Ena
000f.ed00.02bd   18/1      87    No    00d01h03m17s  H44  Ena
000f.ed00.00c9   18/1      87    No    00d01h03m17s  H44  Ena
```

Syntax: **show auth-mac-addresses unauthorized-mac**

[Table 313](#) explains the information in the output.

Displaying multi-device port authentication information for a port

To display a summary of Multi-Device Port Authentication for ports on a device, enter the following command

```
Brocade#show auth-mac-addresses ethernet 18/1
```

```
-----
MAC Address      Port      Vlan  Authenticated Time   Age  Dot1x
-----
000f.ed00.0001   18/1      87    Yes    00d01h03m17s  Ena  Ena
000f.ed00.012d   18/1      87    Yes    00d01h03m17s  Ena  Ena
000f.ed00.0321   18/1      87    No     00d01h03m17s  H52  Ena

```

Syntax: **show auth-mac-address ethernet <port>**

[Table 313](#) explains the information in the output.

TABLE 313 Output of show auth-mac-address

Field	Description
MAC Address	The MAC addresses learned on the port. If the packet for which multi-device port authentication was performed also contained an IP address, the IP address is also displayed.
Port	ID of the port on which the MAC address was learned.
VLAN	VLAN of which the port is a member.
Authenticated	Whether the MAC address has been authenticated by the RADIUS server.

TABLE 313 Output of show auth-mac-address (Continued)

Field	Description
Time	The time the MAC address was authenticated. If the clock is set on the Brocade device, then the actual date and time are displayed. If the clock has not been set, the time is displayed relative to when the device was last restarted.
Age	The age of the MAC address entry in the authenticated MAC address list.
Dot1x	Indicates if 802.1X authentication is enabled or disabled for the MAC address

Displaying multi-device port authentication settings and authenticated MAC addresses

To display the multi-device port authentication settings and authenticated MAC addresses for a port where the feature is enabled, enter the following command.

Syntax: `show auth-mac-address [detail] [ethernet <port>]`

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Omitting the **ethernet** *<port>* parameter displays information for all interfaces where the multi-device port authentication feature is enabled.

```

The following table describes the information displayed by the **show auth-mac-addresses detailed** command.

TABLE 314 Output from the **show auth-mac-addresses detailed** command

Field	Description
Port	The port to which this information applies.
Dynamic-Vlan Assignment	Whether RADIUS dynamic VLAN assignment has been enabled for the port.
RADIUS failure action	What happens to traffic from a MAC address for which RADIUS authentication has failed either block the traffic or assign the MAC address to a restricted VLAN.
Failure restrict use dot1x	Indicates if 802.1x traffic that failed multi-device port authentication, but succeeded 802.1x authentication to gain access to the network.
Override-restrict-vlan	Whether a port can be dynamically assigned to a VLAN specified by a RADIUS server, if the port had been previously placed in the restricted VLAN because a previous attempt at authenticating a MAC address on that port failed.
Port Default Vlan	The VLAN to which the port is assigned, and whether the port had been dynamically assigned to the VLAN by a RADIUS server.
Port VLAN state	Indicates the state of the port VLAN. The State can be one of the following "Default", "RADIUS Assigned" or "Restricted".

TABLE 314 Output from the **show auth-mac-addresses detailed** command (Continued)

Field	Description
802.1X override Dynamic PVID	Indicates if 802.1X can dynamically assign a Port VLAN ID (PVID).
override return to PVID	If a port PVID is assigned through the multi-device port authentication feature, and 802.1X authentication subsequently specifies a different PVID, then the PVID specified through 802.1X authentication overrides the PVID specified through multi-device port authentication. This line indicates the PVID the port will use if 802.1X dynamically assigns PVID.
Original PVID	The originally configured (not dynamically assigned) PVID for the port.
DOS attack protection	Whether denial of service attack protection has been enabled for multi-device port authentication, limiting the rate of authentication attempts sent to the RADIUS server.
Accepted Mac Addresses	The number of MAC addresses that have been successfully authenticated.
Rejected Mac Addresses	The number of MAC addresses for which authentication has failed.
Authentication in progress	The number of MAC addresses for which authentication is pending. This is the number of MAC addresses for which an Access-Request message has been sent to the RADIUS server, and for which the RADIUS server has not yet sent an Access-Accept message.
Authentication attempts	The total number of authentication attempts made for MAC addresses on an interface, including pending authentication attempts.
RADIUS timeouts	The number of times the session between the Brocade device and the RADIUS server timed out.
RADIUS timeout action	Action to be taken by the RADIUS server if it times out.
MAC address on the PVID	Number of MAC addresses on the PVID.
MAC address authorized on PVID	Number of authorized MAC addresses on the PVID.
Aging of MAC-sessions	Whether software aging of MAC addresses is enabled.
Port move-back VLAN	Indicates the destination VLAN when a RADIUS assigned VLAN is removed. By default, it would return the configured VLAN.
Max-Age of sw MAC-sessions	The configured software aging period for MAC addresses.
hw age for denied MAC	The hardware aging period for blocked MAC addresses. The MAC addresses are dropped in hardware ones the aging period expires.
MAC Filter applied	Indicates whether a MAC address filter has been applied to this port to specify pre-authenticated MAC addresses.
Dynamic ACL applied	Indicates whether a dynamic ACL was applied to this port.
num Dynamic Tagged Vlan	The number of dynamically tagged VLANs on this port.
Dynamic Tagged Vlan list	The list of dynamically tagged VLANs on this port. In this example, 1025 (1/1) indicates that there was one MAC session and one learned MAC address for VLAN 1025. Likewise, 4060 (1/0) indicates that there was one MAC session and no learned MAC addresses for VLAN 4060.
MAC Address	The MAC addresses learned on the port. If the packet for which multi-device port authentication was performed also contained an IP address, then the IP address is displayed as well.
RADIUS Server	The IP address of the RADIUS server used for authenticating the MAC addresses.

TABLE 314 Output from the **show auth-mac-addresses detailed** command (Continued)

Field	Description
Authenticated	Whether the MAC address has been authenticated by the RADIUS server.
Time	The time at which the MAC address was authenticated. If the clock is set on the Brocade device, then the actual date and time are displayed. If the clock has not been set, then the time is displayed relative to when the device was last restarted.
Age	The age of the MAC address entry in the authenticated MAC address list.
Dot1x	Indicated if 802.1X authentication is enabled or disabled for the MAC address

Displaying the MAC authentication table for FCX devices

For FCX devices, there are three commands you can use to display MAC authentication information:

- `show table <mac address>`
- `show table allowed-mac`
- `show table denied-mac`

This section describes the output for these commands.

To display MAC authentication information for FCX devices, enter the **show table <mac address>** command as shown.

```
Brocade#show table 0000.0010.1002
```

Syntax: `show table <mac address>`

The `<mac address>` variable is the specified MAC address.

```
Brocade#show table 0000.0010.1002
```

```
-----
MAC Address Port Vlan Authenticated Time Age dot1x
-----
0000.0010.1002 2/1/48 2 Yes 00d00h30m57s Ena Dis
Brocade#
```

To display the table of allowed (authenticated) mac addresses enter the **show table allowed-mac** command as shown.

Syntax: `show table allowed-mac`

```
Brocade#show table allowed-mac
```

```
-----
MAC Address PortVlanAuthenticatedTimeAgedot1x
-----
0000.0010.100a 1/1/1 2 Yes 00d00h30m57s Ena Dis
0000.0010.100b 1/1/1 2 Yes 00d00h31m00s Ena Dis
0000.0010.1002 2/1/48 2 Yes 00d00h30m57s Ena Dis
0000.0010.1003 2/1/48 2 Yes 00d00h30m57s Ena Dis
0000.0010.1004 2/1/48 2 Yes 00d00h30m57s Ena Dis
Brocade#
```

To display the table of allowed mac addresses enter the **show table denied-mac** command as shown.

Syntax: **show table** <mac address>

The <mac address> variable is the specified MAC address.

```
Brocade#show table denied-mac
```

MAC Address	Port	Vlan	Authenticated	Time	Age	dot1x
0000.0010.1021	2/1/48	4092	No	00d00h32m48s	H8	Dis
0000.0010.1022	2/1/48	4092	No	00d00h32m48s	H8	Dis

```
Brocade#
```

To display MAC authentication for a specific port, enter the **show table ethernet** <stack-unit/slot/port> command as shown.

```
Brocade#show table eth 2/1/48
```

MAC Address	Port	Vlan	Authenticated	Time	Age	CAM	MAC	Dot1x	Type	Pri	Index	Index
0000.0010.1002	2/1/48	2	Yes	00d00h30m	57s	Ena	0000	70d4	Dis	Dyn	0

Example port authentication configurations

This section includes configuration examples of multi-device port authentication with dynamic VLAN assignment, and multi-device port authentication and 802.1X authentication.

Multi-device port authentication with dynamic VLAN assignment

[Figure 197](#) illustrates multi-device port authentication with dynamic VLAN assignment on a Brocade device. In this configuration, a PC and an IP phone are connected to a hub, which is connected to port e1 on a Brocade device. The profile for the PC MAC address on the RADIUS server specifies that the PC should be dynamically assigned to VLAN 102, and the RADIUS profile for the IP phone specifies that it should be dynamically assigned to VLAN 3.

FIGURE 196 Using multi-device port authentication with dynamic VLAN assignment

In this example, multi-device port authentication is performed for both devices. If the PC is successfully authenticated, port e1 PVID is changed from VLAN 1 (the DEFAULT-VLAN) to VLAN 102. If authentication for the PC fails, then the PC can be placed in a specified "restricted" VLAN, or traffic from the PC can be blocked in hardware. In this example, if authentication for the PC fails, the PC would be placed in VLAN 1023, the restricted VLAN.

If authentication for the IP phone is successful, then port e1 is added to VLAN 3. If authentication for the IP phone fails, then traffic from the IP phone would be blocked in hardware. (Devices sending tagged traffic cannot be placed in the restricted VLAN.)

The portion of the running-config related to multi-device port authentication is as follows.

```
mac-authentication enable
mac-authentication auth-fail-vlan-id 1023

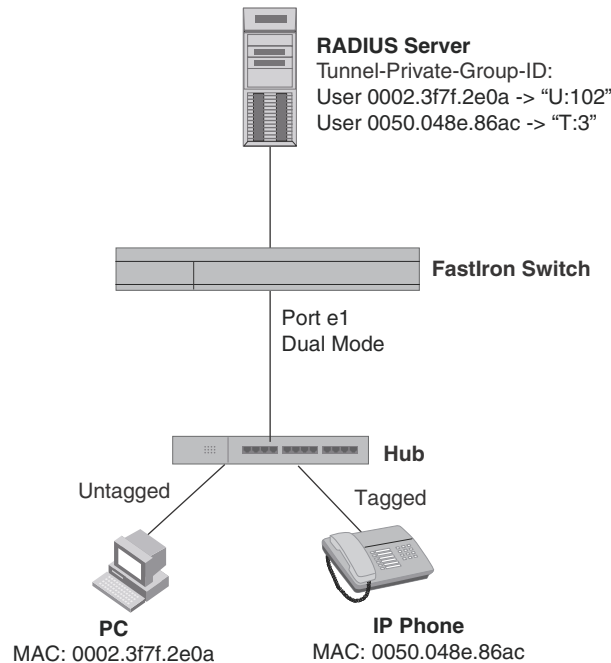

interface ethernet 1
  dual-mode
  mac-authentication enable
  mac-authentication auth-fail-action restrict-vlan
  mac-authentication enable-dynamic-vlan
  mac-authentication disable-ingress-filtering
```

The **mac-authentication disable-ingress-filtering** command enables tagged packets on the port, even if the port is not a member of the VLAN. If this feature is not enabled, authentication works as in ["Example 2 – multi-device port authentication with dynamic VLAN assignment"](#)

Example 2 – multi-device port authentication with dynamic VLAN assignment

Figure 197 illustrates multi-device port authentication with dynamic VLAN assignment on a Brocade device. In this configuration, a PC and an IP phone are connected to a hub, which is connected to port e1 on a Brocade device. Port e1 is configured as a dual-mode port. Also, **mac-authentication disable-ingress-filtering** is enabled on the port. The profile for the PC MAC address on the RADIUS server specifies that the PC should be dynamically assigned to VLAN 102, and the RADIUS profile for the IP phone specifies that it should be dynamically assigned to VLAN 3.

FIGURE 197 Using multi-device port authentication with dynamic VLAN assignment

In this example, multi-device port authentication is performed for both devices. If the PC is successfully authenticated, dual-mode port e1 PVID is changed from the VLAN 1 (the DEFAULT-VLAN) to VLAN 102. If authentication for the PC fails, then the PC can be placed in a specified "restricted" VLAN, or traffic from the PC can be blocked in hardware. In this example, if authentication for the PC fails, the PC would be placed in VLAN 1023, the restricted VLAN.

If authentication for the IP phone is successful, then dual-mode port e1 is added to VLAN 3. If authentication for the IP phone fails, then traffic from the IP phone would be blocked in hardware. (Devices sending tagged traffic cannot be placed in the restricted VLAN.)

NOTE

This example assumes that the IP phone initially transmits untagged packets (for example, CDP or DHCP packets), which trigger the authentication process on the Brocade device and client lookup on the RADIUS server. If the phone sends only tagged packets and the port (e1) is not a member of that VLAN, authentication would not occur. In this case, port e1 must be added to that VLAN prior to authentication.

The part of the running-config related to multi-device port authentication would be as follows.

Example port authentication configurations

```
mac-authentication enable
mac-authentication auth-fail-vlan-id 1023

interface ethernet 1
  mac-authentication enable
  mac-authentication auth-fail-action restrict-vlan
  mac-authentication enable-dynamic-vlan
  dual-mode
```

Examples of multi-device port authentication and 802.1X authentication configuration on the same port

The following examples show configurations that use multi-device port authentication and 802.1X authentication on the same port.

Example 1 – Multi-device port authentication and 802.1x authentication on the same port

[Figure 198](#) illustrates an example configuration that uses multi-device port authentication and 802.1X authentication on the same port. In this configuration, a PC and an IP phone are connected to port e 1/3 on a Brocade device. Port e 1/3 is configured as a dual-mode port.

The profile for the PC MAC address on the RADIUS server specifies that the PC should be dynamically assigned to VLAN "Login-VLAN", and the RADIUS profile for the IP phone specifies that it should be dynamically assigned to the VLAN named "IP-Phone-VLAN". When User 1 is successfully authenticated using 802.1X authentication, the PC is then placed in the VLAN named "User-VLAN".

NOTE

This example assumes that the IP phone initially transmits untagged packets (for example, CDP or DHCP packets), which trigger the authentication process on the Brocade device and client lookup on the RADIUS server. If the phone sends only tagged packets and the port (e 1/3) is not a member of that VLAN, authentication would not occur. In this case, port e 1/3 must be added to that VLAN prior to authentication.

FIGURE 198 Using multi-device port authentication and 802.1X authentication on the same port

When the devices attempt to connect to the network, they are first subject to multi-device port authentication.

When the MAC address of the IP phone is authenticated, the Access-Accept message from the RADIUS server specifies that the IP phone port be placed into the VLAN named “IP-Phone-VLAN”, which is VLAN 7. The Foundry-802_1x-enable attribute is set to 0, meaning that 802.1X authentication is skipped for this MAC address. Port e 1/3 is placed in VLAN 7 as a tagged port. No further authentication is performed.

When the PC MAC address is authenticated, the Access-Accept message from the RADIUS server specifies that the PVID for the PC port be changed to the VLAN named “Login-VLAN”, which is VLAN 1024. The Foundry-802_1x-enable attribute is set to 1, meaning that 802.1X authentication is required for this MAC address. The PVID of the port e 1/3 is temporarily changed to VLAN 1024, pending 802.1X authentication.

When User 1 attempts to connect to the network from the PC, he is subject to 802.1X authentication. If User 1 is successfully authenticated, the Access-Accept message from the RADIUS server specifies that the PVID for User 1 port be changed to the VLAN named “User-VLAN”, which is VLAN 3. If 802.1X authentication for User 1 is unsuccessful, the PVID for port e 1/3 is changed to that of the restricted VLAN, which is 1023, or untagged traffic from port e 1/3 can be blocked in hardware.

The part of the running-config related to port e 1/3 would be as follows.

```
interface ethernet 1/3
dot1x port-control auto
mac-authentication enable
dual-mode
```

When the PC is authenticated using multi-device port authentication, the port PVID is changed to “Login-VLAN”, which is VLAN 1024 in this example.

When User 1 is authenticated using 802.1X authentication, the port PVID is changed to “User-VLAN”, which is VLAN 3 in this example.

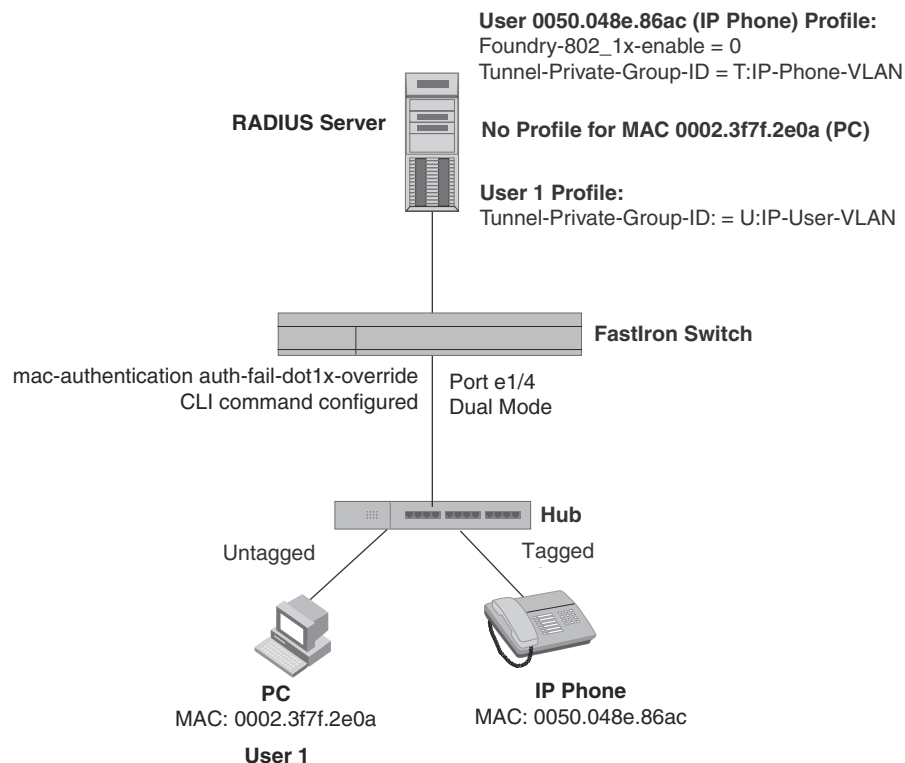

Example 2 – Creating a profile on the RADIUS server for each MAC address

The configuration in [Figure 199](#) requires that you create a profile on the RADIUS server for each MAC address to which a device or user can connect to the network. In a large network, this can be difficult to implement and maintain.

As an alternative, you can create MAC address profiles only for those devices that do not support 802.1X authentication, such as IP phones and printers, and configure the device to perform 802.1X authentication for the other devices that do not have MAC address profiles, such as user PCs. To do this, you configure the device to perform 802.1X authentication when a device fails multi-device port authentication.

[Figure 199](#) shows a configuration where multi-device port authentication is performed for an IP phone, and 802.1X authentication is performed for a user PC. There is a profile on the RADIUS server for the IP phone MAC address, but not for the PC MAC address.

FIGURE 199 802.1X Authentication is performed when a device fails multi-device port authentication

Multi-device port authentication is initially performed for both devices. The IP phone MAC address has a profile on the RADIUS server. This profile indicates that 802.1X authentication should be skipped for this device, and that the device port be placed into the VLAN named “IP-Phone-VLAN”.

Since there is no profile for the PC MAC address on the RADIUS server, multi-device port authentication for this MAC address fails. Ordinarily, this would mean that the PVID for the port would be changed to that of the restricted VLAN, or traffic from this MAC would be blocked in hardware. However, the device is configured to perform 802.1X authentication when a device fails multi-device port authentication, so when User 1 attempts to connect to the network from the PC, he is subject to 802.1X authentication. If User 1 is successfully authenticated, the PVID for port e 1/4 is changed to the VLAN named "User-VLAN".

NOTE

This example assumes that the IP phone initially transmits untagged packets (for example, CDP or DHCP packets), which trigger the authentication process on the Brocade device and client lookup on the RADIUS server. If the phone sends only tagged packets and the port (e 1/4) is not a member of that VLAN, authentication would not occur. In this case, port e 1/4 must be added to that VLAN prior to authentication.

To configure the device to perform 802.1X authentication when a device fails multi-device port authentication, enter the following command.

```
Brocade(config)#mac-authentication auth-fail-dot1x-override
```

Syntax: [no] mac-authentication auth-fail-dot1x-override

Example port authentication configurations

Web Authentication

[Table 315](#) lists individual Brocade switches and the Web Authentication features they support. These features are supported in the Layer 2, base Layer 3, edge Layer 3, and full Layer 3 software images, except where explicitly noted.

TABLE 315 Supported Web Authentication features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
Enabling and disabling Web Authentication	Yes	Yes	Yes	Yes	Yes
Configuring the Web Authentication mode	Yes	Yes	Yes	Yes	Yes
Web Authentication options in this chapter	Yes	Yes	Yes	Yes	Yes

Web authentication overview

Authentication is important in enterprise networks because the network is considered a secure area: it contains sensitive data and a finite amount of resources. Unauthorized users must be prevented from accessing the network to protect the sensitive data and prevent the unnecessary consumption of resources.

The ideal authentication method blocks unauthorized users at the earliest possible opportunity. For internal enterprise networks, this can be controlled at the edge switch port. Two popular forms of port-based security authentication used at the edge switch are multi-device port authentication and 802.1x. Multi-device port authentication authenticates the MAC addresses of hosts or users that are attempting to access the network. This type of authentication requires no intervention from the host or user who is attempting to be authenticated. It is easy to use, but it can only authorize hosts; it cannot be used to authorize users. 802.1x authentication can authorize users or hosts. It is more flexible than the multi-device port authentication method; however, it requires more support, configuration, maintenance and user intervention than multi-device port authentication.

The Brocade Web authentication method provides an ideal port-based authentication alternative to multi-device port authentication without the complexities and cost of 802.1x authentication. Hosts gain access to the network by opening a Web browser and entering a valid URL address using HTTP or HTTPS services. Instead of being routed to the URL, the host browser is directed to an authentication Web page on the FastIron switch. The Web page prompts the host to enter a user ID and password or a passcode. The credentials a host enters are used by a trusted source to authenticate the host MAC address. (Multiple MAC addresses can be authenticated with the same user name and password.)

If the authentication is unsuccessful, the appropriate page is displayed on the host browser. The host is asked to try again or call for assistance, depending on what message is configured on the Web page. If the host MAC address is authenticated by the trusted source, a Web page is displayed with a hyperlink to the URL the host originally entered. If the user clicks on the link, a new window is opened and the user is directed to the requested URL.

While a MAC address is in the authenticated state, the host can forward data through the FastIron switch. The MAC address remains authenticated until one of the following events occurs:

- The host MAC address is removed from a list of MAC addresses that are automatically authenticated. (Refer to [“Specifying hosts that are permanently authenticated”](#) on page 1902).
- The re-authentication timer expires and the host is required to re-authenticate (Refer to [“Configuring the re-authentication period”](#) on page 1903).
- The host has remained inactive for a period of time and the inactive period timer has expired. (Refer to [“Forcing re-authentication after an inactive period”](#) on page 1906.)
- All the ports on the VLAN on which Web Authentication has been configured are in a down state. All MAC addresses that are currently authenticated are de-authenticated (Refer to [“Forcing re-authentication when ports are down”](#) on page 1905.)
- The authenticated client is cleared from the Web Authentication table. (Refer to [“Clearing authenticated hosts from the web authentication table”](#) on page 1903).

The FastIron switch can be configured to automatically authenticate a host MAC address. The host will not be required to login or re-authenticate (depending on the re-authentication period) once the MAC address passes authentication.

A host that is logged in and authenticated remains logged in indefinitely, unless a re-authentication period is configured. When the re-authentication period ends, the host is logged out. A host can log out at any time by pressing the Logout button in the Web Authentication Success page.

NOTE

The host can log out as long as the Logout window (Success page) is visible. If the window is accidentally closed, the host cannot log out unless the re-authentication period ends or the host is manually cleared from the Web Authentication table.

Web authentication configuration considerations

Web Authentication is modeled after other RADIUS-based authentication methods currently available on Brocade edge switches. However, Web Authentication requires a Layer 3 protocol (TCP/IP) between the host and the authenticator. Therefore, to implement Web Authentication, you must consider the following configuration and topology configuration requirements:

- Web authentication works only when both the HTTP and HTTPS servers are enabled on the device.
- Web Authentication works only on the default HTTP or HTTPS port.
- The host must have an IP address prior to Web Authentication. This IP address can be configured statically on the host; however, DHCP addressing is also supported.
- If you are using DHCP addressing, a DHCP server must be in the same broadcast domain as the host. This DHCP server does not have to be physically connected to the switch. Also, DHCP assist from a router may be used.

- Web Authentication, 802.1X port security, and multi-device port authentication are not supported concurrently on the same port.
- Web Authentication is not supported on an MCT VLAN.

The following applies to Web Authentication in the Layer 2 switch image:

- If the management VLAN and Web Authentication VLAN are in different IP networks, make sure there is at least one routing element in the network topology that can route between these IP networks.

The following are required for Web Authentication in the base Layer 3 and full Layer 3 images:

- Each Web Authentication VLAN must have a virtual interface (VE).
- The VE must have at least one assigned IPv4 address.

Web Authentication is enabled on a VLAN. That VLAN becomes a Web Authentication VLAN that does the following:

- Forwards traffic from authenticated hosts, just like a regular VLAN.
- Blocks traffic from unauthenticated hosts except from ARP, DHCP, DNS, HTTP, and HTTPs that are required to perform Web Authentication.

Figure 200 shows the basic components of a network topology where Web Authentication is used. You will need:

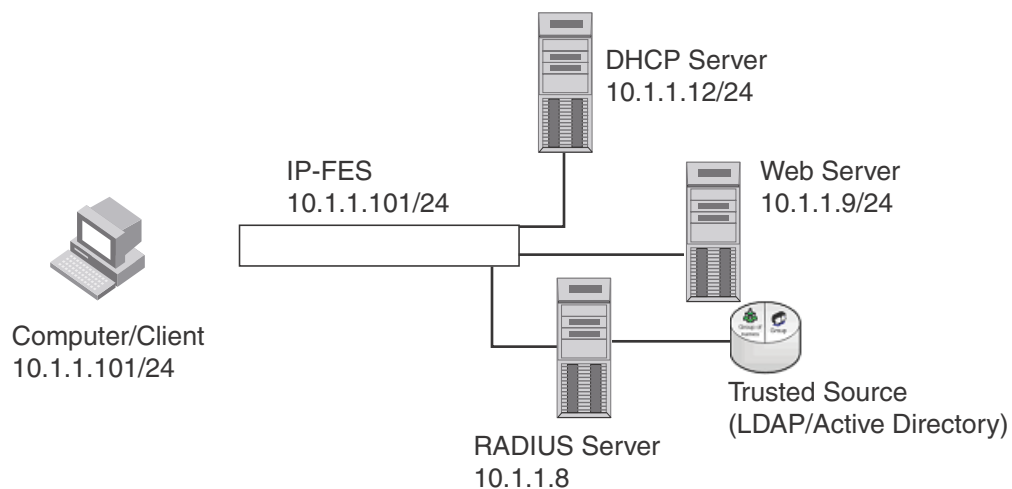

- A Brocade FastIron switch running a software release that supports Web Authentication
- DHCP server, if dynamic IP addressing is to be used
- Computer/host with a web browser

Your configuration may also require a RADIUS server with some Trusted Source such as LDAP or Active Directory.

NOTE

The Web server, RADIUS server, and DHCP server can all be the same server.

FIGURE 200 Basic topology for web authentication

Web authentication configuration tasks

Follow the steps given below to configure Web Authentication on a device.

1. Set up any global configuration required for the FastIron switch, RADIUS server, Web server and other servers.
 - On a Layer 2 FastIron switch, make sure the FastIron switch has an IP address.

```
Brocade# configure terminal
Brocade(config)#ip address 10.1.1.10/24
```

- On a Layer 3 FastIron switch, assign an IP address to a virtual interface (VE) for each VLAN on which Web Authentication will be enabled.

```
Brocade#configure terminal
Brocade(config)#vlan 10
Brocade(config-vlan-10)#router-interface ve1
Brocade(config-vlan-10)#untagged e 1/1/1 to 1/1/10
Brocade(config-vlan-10)#interface ve1
Brocade(config-vif-1)#ip address 1.1.2.1/24
```

2. By default, Web Authentication will use a RADIUS server to authenticate host usernames and passwords, unless it is configured to use a local user database. If Web Authentication will use a RADIUS server, you must configure the RADIUS server and other servers. For example, if your RADIUS server has an IP address of 192.168.1.253, then use the CLI to configure the following global CLI commands on the FastIron switch.

```
Brocade(config)# radius-server host 10.1.1.8
Brocade(config)# radius-server key $GSig@U\
```

NOTE

Remember the RADIUS key you entered. You will need this key when you configure your RADIUS server.

3. Web authentication can be configured to use secure (HTTPS) or non-secure (HTTP) login and logout pages. By default, HTTPS is used.

To enable the non-secure Web server on the FastIron switch, enter the following command.

```
Brocade(config)# web-management HTTP
Brocade(config)#vlan 10
Brocade(config-vlan-10)webauth
Brocade(config-vlan-10-webauth)#no secure-login
```

To enable the secure Web server on the FastIron switch, enter the following command.

```
Brocade(config)# web-management HTTPS
Brocade(config)#vlan 10
Brocade(config-vlan-10)webauth
Brocade(config-vlan-10-webauth)#secure-login
```

4. If the secure Web server is used, in order to access a secure Web page, the Web server needs to provide a key. This key is exchanged using a certificate. A certificate is a digital document that is issued by a trusted source that can validate the authenticity of the certificate and the Web server that is presenting it. Therefore the switch must have a certificate for web authentication to work. There are two choices for providing the switch with a certificate:

- Upload one using the following global CLI command.

```
Brocade(config)# ip ssl private-key-file tftp <ip-addr> <key-filename>
```

- Generate one using the following global CLI command.

```
Brocade(config)#crypto-ssl certificate generate default_cert
```

5. Create a Web Authentication VLAN and enable Web Authentication on that VLAN.

```
Brocade(config)#vlan 10
Brocade(config-vlan-10)#webauth
Brocade(config-vlan-10-webauth)#enable
```

Once enabled, the CLI changes to the "webauth" configuration level. In the example above, VLAN 10 will require hosts to be authenticated using Web Authentication before they can forward traffic.

6. Configure the Web Authentication mode:

- **Username and password** – Blocks users from accessing the switch until they enter a valid username and password on a web login page.
- **Passcode** – Blocks users from accessing the switch until they enter a valid passcode on a web login page.
- **None** – Blocks users from accessing the switch until they press the 'Login' button. A username and password or passcode is not required.

Refer to [“Web authentication mode configuration”](#) on page 1892.

7. Configure other Web Authentication options (refer to [“Web authentication options configuration”](#) on page 1901).

Enabling and disabling web authentication

Web Authentication is disabled by default. To enable it, enter the following commands.

```
Brocade(config)#vlan 10
Brocade(config-vlan-10)#webauth
Brocade(config-vlan-10-webauth)#enable
```

The first command changes the CLI level to the VLAN configuration level. The second command changes the configuration level to the Web Authentication VLAN level. The last command enables Web Authentication. In the example above, VLAN 10 will require hosts to be authenticated using Web Authentication before they can forward traffic.

Syntax: webauth

FastIron devices support a maximum of two Web Authentication VLANs.

Syntax: [no] enable

Enter the **no enable** command to disable Web Authentication.

Web authentication mode configuration

You can configure the FastIron switch to use one of three Web Authentication modes:

- **Username and password** – Block users from accessing the switch until they enter a valid username and password on a web login page. Refer to [“Using local user databases”](#) on page 1892.
- **Passcode** – Blocks users from accessing the switch until they enter a valid passcode on a web login page. Refer to [“Passcodes for user authentication”](#) on page 1896.
- **None** – Blocks users from accessing the switch until they press the 'Login' button. A username and password or passcode is not required. Refer to [“Automatic authentication”](#) on page 1900.

The following sections describe how to configure these Web Authentication modes.

Using local user databases

Web Authentication supports the use of local user databases consisting of usernames and passwords, to authenticate devices. Users are blocked from accessing the switch until they enter a valid username and password on a web login page.

Once a user successfully authenticates through username and password, the user is subjected to the same policies as for RADIUS-authenticated devices (for example, the re-authentication period, maximum number of users allowed, etc.). Similarly, once a user fails username and password authentication, the user is subjected to the same policies as for devices that fail RADIUS authentication.

You can create up to ten local user databases on the FastIron switch either by entering a series of CLI commands, or by uploading a list of usernames and passwords from a TFTP file to the FastIron switch. The user databases are stored locally, on the FastIron switch.

Configuring a local user database

Follow the steps given below to configure a local user database.

1. Create the local user database.
2. Add records to the local user database either by entering a series of CLI commands, or by importing a list of user records from an ASCII text file on the TFTP server to the FastIron switch.
3. Set the local user database authentication mode.
4. If desired, set the authentication method (RADIUS/local) failover sequence.
5. Assign a local user database to a Web Authentication VLAN.

Creating a local user database

The FastIron switch supports a maximum of ten local user databases, each containing up to 30 user records. Each user record consists of a username and password.

To create a local user database, enter a command such as the following.

```
Brocade#(config)#local-userdb userdb1
Brocade#(config-localuserdb-userdb1)#
```

This command creates a local user database named **userdb1**. To add user records to this database, refer to [“Adding a user record to a local user database”](#) on page 1893.

Syntax: **local-userdb** <db-name>

You can create up to ten local user databases for Web Authentication.

For <db-name>, enter up to 31 alphanumeric characters.

Adding a user record to a local user database

To add a user record, enter commands such as the following.

```
Brocade#(config)#local-userdb userdb1
Brocade#(config-localuserdb-userdb1)#username marcia password bunch4
```

The first command changes the configuration level to the local user database level for **userdb1**. If the database does not already exist, it is created. The second command adds the user record **marcia** to the **userdb1** database.

Syntax: **username** <username> **password** <password>

For <username>, enter up to 31 ASCII characters.

For <password>, enter up to 29 ASCII characters.

You can add up to 30 usernames and passwords to a local user database.

To view a list of users in a local user database, use the CLI command **vlan-mod-port-userdb**. Refer to [“Displaying a list of local user databases”](#) on page 1919.

Deleting a user record from a local user database

To delete a user record from the local user database, enter commands such as the following.

```
Brocade#(config)#local-userdb userdb1
Brocade#(config-localuserdb-userdb1)#no username marcia
```

The first command changes the configuration level to the local user database level for **userdb1**. The second command deletes the user record **marcia** from the **userdb1** database.

Syntax: **no username** <username>

Deleting All user records from a local user database

To delete all user records from a local user database, enter the **delete-all** command.

```
Brocade#(config-localuserdb-userdb1)#delete-all
```

Syntax: **delete-all**

Creating a text file of user records

If desired, you can use the TFTP protocol to import a list of usernames and passwords from a text file on a TFTP server to the FastIron switch. The text file to be imported must be in the following ASCII format.

```
[delete-all]
[no] username <username1> password <password1> <cr>
```

```
[no] username <username2> password <password2> <cr>
...
```

The [delete-all] keyword indicates that the user records in the text file will replace the user records in the specified local user database on the FastIron switch. If the [delete-all] keyword is not present, the new user records will be *added* to the specified local user database on the FastIron switch. The [delete-all] keyword is optional. If present, it must appear on the first line, before the first user record in the text file.

The optional [no] keyword indicates that the user entry will be deleted from the specified local user database on the FastIron switch.

User records that already exist in the local user database will be updated with the information in the text file when it is uploaded to the switch.

For <username1>, <username2>, etc., enter up to 31 ASCII characters.

For <password1>, <password2>, etc., enter up to 29 ASCII characters.

Be sure to Insert a cursor return (<cr>) after each user record.

You can enter up to 30 user records per text file.

Importing a text file of user records from a TFTP server

NOTE

Before importing the file, make sure it adheres to the ASCII text format described in the previous section, [“Creating a text file of user records”](#) on page 1893.

To import a text file of user records from a TFTP server to the FastIron switch, enter a command such as the following.

```
Brocade#(config-localuserdb-userdb1)#import-users tftp 192.168.1.1 filename
userdb1
```

Syntax: `import-users tftp <ip-address> filename <filename>`

The <ip-address> parameter specifies the IPv4 address of the TFTP server on which the desired text file resides.

The <filename> parameter specifies the name of the image on the TFTP server.

Using a RADIUS server as the web authentication method

By default, Web Authentication will use a RADIUS server to authenticate hosts' usernames and passwords, unless the device is configured to use the local user database (see the previous section). To configure the FastIron switch to use a RADIUS server, refer to [“RADIUS security”](#) on page 157. You must also perform the following steps.

1. Configure the RADIUS server information on the FastIron switch. Enter a command such as the following.

```
Brocade(config)#radius-server host 10.1.1.8 auth-port 1812 acct-port 1813
default key $GSig@U\
```

NOTE

Web Authentication will use the first reachable RADIUS server listed in the configuration. The **use-radius-server** on individual ports is not supported for Web Authentication.

2. Enable the username and password authentication mode.

```
Brocade(config-vlan-10-webauth)#auth-mode username-password
```

3. Enable the RADIUS authentication method. Refer to [“Setting the local user database authentication method”](#) on page 1895 or [“Setting the web authentication failover sequence”](#) on page 1895

Setting the local user database authentication method

By default, the FastIron switch uses a RADIUS server to authenticate users in a VLAN. The previous section describes how to configure a RADIUS server to authenticate users in a VLAN. To configure the switch to instead use a local user database to authenticate users in a VLAN, enter the following command.

```
Brocade(config-vlan-10-webauth)#auth-mode username-password auth-methods local
```

Syntax: `auth-mode username-password auth-methods local`

To revert back to using the RADIUS server, enter the following command.

```
Brocade(config-vlan-10-webauth)#auth-mode username-password auth-methods radius
```

Syntax: `auth-mode username-password auth-methods radius`

Setting the web authentication failover sequence

You can optionally specify a failover sequence for RADIUS and local user database authentication methods. For example, you can configure Web Authentication to first use a local user database to authenticate users in a VLAN. If the local user database is not available, it will use a RADIUS server. Enter the following command.

```
Brocade(config-vlan-10-webauth)#auth-mode username-password auth-methods local radius
```

Syntax: `auth-mode username-password auth-methods <method1> <method2>`

For `<method1>` `<method2>`, enter **radius local** or **local radius**.

Assigning a local user database to a web authentication VLAN

After creating or importing a local user database on the FastIron switch and setting the local user database authentication method to **local**, you can configure a Web Authentication VLAN to use the database to authenticate users in a VLAN. To do so, enter a command such as the following.

```
Brocade(config-vlan-10-webauth)#auth-mode username-password local-user-database userdb1
```

These commands configure Web Authentication to use the usernames and passwords in the userdb1 database to authenticate users in VLAN 10.

Syntax: `[no] auth-mode username-password local-user-database <db-name>`

For `<db-name>`, enter a valid local user database.

Use the **no** form of the command to remove the database from the Web Authentication VLAN.

Passcodes for user authentication

Web Authentication supports the use of passcodes to authenticate users. Users are blocked from accessing the switch until they enter a valid passcode on a web login page. Unlike username and password authentication, passcode authentication uses a simple number to authenticate users. The simplicity of a passcode reduces user errors and lowers the overhead of supporting and managing simple tasks, such as Internet access for guests and visitors in the office.

When passcodes are enabled, the system will automatically generate them every 1440 minutes (24 hours), and when the system boots up. You can optionally create up to four static passcodes which will be used in conjunction with the dynamic passcodes generated by the system.

Configuring passcode authentication

Follow the steps given below to configure the device to use the passcode authentication mode.

1. Optionally create up to four static passcodes
2. Enable passcode authentication
3. Configure other options

Creating static passcodes

Static passcodes can be used for troubleshooting purposes, or for networks that want to use passcode authentication, but do not have the ability to support automatically-generated passcodes (for example, the network does not fully support the use of SNMP traps or Syslog messages with passcodes).

Manually-created passcodes are used in conjunction with dynamic passcodes. You can configure up to four static passcodes that never expire. Unlike dynamically-created passcodes, static passcodes are saved to flash memory. By default, there are no static passcodes configured on the switch.

To create static passcodes, enter commands such as the following.

```
Brocade(config-vlan-10-webauth)#auth-mode passcode static 3267345
Brocade(config-vlan-10-webauth)#auth-mode passcode static 56127
```

Syntax: `auth-mode passcode static <passcode>`

For `<passcode>`, enter a number from 4 to 16 digits in length. You can create up to four static passcodes, each with a different length. Static passcodes do not have to be the same length as passcodes that are automatically generated.

After creating static passcodes, you can enable passcode authentication as described in the next section.

To view the passcodes configured on the switch, use the **show webauth vlan <vlan-id> passcode** command. Refer to [“Displaying passcodes”](#) on page 1920.

Enabling passcode authentication

To enable passcode authentication, enter the following command.

```
Brocade(config-vlan-10-webauth)#auth-mode passcode
```

This command enables Web Authentication to use dynamically-created passcodes to authenticate users in the VLAN. If the configuration includes static passcodes, they are used in conjunction with dynamically-created passcodes.

Syntax: [no]auth-mode passcode

Enter **no auth-mode passcode** to disable passcode authentication.

Configuring the length of dynamically-generated passcodes

By default, dynamically-generated passcodes are 4 digits in length, for example, 0123. If desired, you can increase the passcode length to up to 16 digits. To do so, enter a command such as the following at the Web Authentication level of the CLI.

```
Brocade(config-vlan-10-webauth)#auth-mode passcode length 10
```

The next dynamically-created passcode will be 10 digits in length, for example, 0123456789.

Syntax: auth-mode passcode length <value>

For <value>, enter a number from 4 to 16.

Configuring the passcode refresh method

Passcode authentication supports two passcode refresh methods:

- **Duration of time** – By default, dynamically-created passcodes are refreshed every 1440 minutes (24 hours). When refreshed, a new passcode is generated and the old passcode expires. You can increase or decrease the *duration of time* after which passcodes are refreshed, or you can configure the device to refresh passcodes at a certain *time of day* instead of after a duration of time.
- **Time of day** – When initially enabled, the *time of day* method will cause passcodes to be refreshed at 0:00 (12:00 midnight). If desired, you can change this time of day, and you can add up to 24 refresh periods in a 24-hour period.

When a passcode is refreshed, the old passcode will no longer work, unless a grace period is configured (refer to [“Configuring a grace period for an expired passcode”](#) on page 1898).

If a user changes the passcode refresh value, the configuration is immediately applied to the current passcode. For example, if the passcode duration is 100 minutes and the passcode was last generated 60 minutes prior, a new passcode will be generated in 40 minutes. However, if the passcode duration is changed from 100 to 75 minutes, and the passcode was last generated 60 minutes prior, a new passcode will be generated in 15 minutes. Similarly, if the passcode duration is changed from 100 to 50 minutes, and the passcode was last generated 60 minutes prior, the passcode will immediately expire and a new passcode will be generated. The same principles apply to the time of day passcode refresh method.

If you configure both *duration of time* and *time of day* passcode refresh values, they are saved to the configuration file. You can switch back and forth between the passcode refresh methods, but only one method can be enabled at a time.

NOTE

Passcodes are not stateful, meaning a software reset or reload will cause the system to erase the passcode. When the FastIron switch comes back up, a new passcode will be generated.

Changing the passcode refresh duration

To change the duration of time after which passcodes are refreshed, enter commands such as the following.

```
Brocade(config-vlan-10-webauth)#auth-mode passcode refresh-type duration 4320
```

The passcode will be refreshed after 4320 minutes (72 hours).

Syntax: `auth-mode passcode refresh-type duration <value>`

For <value>, enter a number from 5 to 9999 minutes. The default is 1440 minutes (24 hours).

Refreshing passcodes at a certain time of the day

You can configure the FastIron switch to refresh passcodes at a certain *time of day*, up to 24 times each day, instead of after a duration of time. When this feature is enabled, by default passcodes will be refreshed at 00:00 (12 midnight).

To configure the switch to refresh passcodes at a certain time of day, enter commands such as the following.

```
Brocade(config-vlan-10-webauth)#auth-mode passcode refresh-type time 6:00
Brocade(config-vlan-10-webauth)#auth-mode passcode refresh-type time 14:30
```

The passcode will be refreshed at 6:00am, 2:30pm, and 0:00 (12 midnight).

Syntax: `[no] auth-mode passcode refresh-type time <hh:mm>`.

<hh:mm> is the hour and minutes. If you do not enter a value for <hh:mm>, by default, passcodes will be refreshed at 00:00 (12:00 midnight). You can configure up to 24 refresh times. Each must be at least five minutes apart.

Enter the **no** form of the command to remove the passcode refresh time of day.

Resetting the passcode refresh time of day configuration

If the FastIron switch is configured to refresh passcodes several times during the day (*time of day* configuration), you can use the following command to delete all of the configured times and revert back to the default time of 00:00 (12 midnight).

```
Brocade(config-vlan-10-webauth)#auth-mode passcode refresh-type time delete-all
```

Syntax: `auth-mode passcode refresh-type time delete-all`

Configuring a grace period for an expired passcode

You can optionally configure a grace period for an expired passcode. The grace period is the period of time that a passcode will remain valid, even after a new passcode is generated. For example, if a five minute grace period is set and the passcode 1234 is refreshed to 5678, both passcodes will be valid for five minutes, after which the 1234 passcode will expire and the 5678 passcode will remain in effect.

To configure the grace period for an expired passcode, enter a command such as the following.

```
Brocade(config-vlan-10-webauth)#auth-mode passcode grace-period 5
```

Syntax: `auth-mode passcode grace-period <value>`

`<value>` is a number between 0 and 5 minutes. 0 means there is no grace period.

NOTE

If the grace period is re-configured while a passcode is already in the grace period, the passcode is not affected by the configuration change. The new grace period will apply only to passcodes that expire *after* the new grace period is set.

Flushing all expired passcodes that are in the grace period

You can delete old passcodes that have expired but are still valid because they are in the grace period. This feature is useful in situations where the old passcodes have been compromised but are still valid because of the grace period. This feature does not affect current valid passcodes or passcodes that newly expire.

To flush out all expired passcodes that are currently in the grace period, enter the following command.

```
Brocade(config-vlan-10-webauth)#auth-mode passcode flush-expired
```

Syntax: `auth-mode passcode flush-expired`

Disabling and re-enabling passcode logging

The software generates a Syslog message and SNMP trap message every time a new passcode is generated and passcode authentication is attempted,. This is the default behavior. If desired, you can disable passcode-related Syslog messages or SNMP trap messages, or both.

The following shows an example Syslog message and SNMP trap message related to passcode authentication.

```
New passcode: 01234567. Expires in 1440 minutes. Old passcode is valid for another 5 minutes.
```

To disable Syslog messages for passcodes, enter the **no auth-mode passcode log syslog** command.

```
Brocade(config-vlan-10-webauth)#no auth-mode passcode log syslog
```

Enter the following command to disable SNMP trap messages for passcodes.

```
Brocade(config-vlan-10-webauth)#no auth-mode passcode log snmp-trap
```

Enter the following command to re-enable Syslog messages for passcodes after they have been disabled.

```
Brocade(config-vlan-10-webauth)#auth-mode passcode log syslog
```

Enter the following command to re-enable SNMP trap messages for passcodes after they have been disabled.

```
Brocade(config-vlan-10-webauth)#auth-mode passcode log snmp-trap
```

Syntax: `[no] auth-mode passcode log syslog | snmp-trap`

Re-sending the passcode log message

If passcode logging is enabled, you can enter a CLI command to retransmit the current passcode to a Syslog message or SNMP trap. To do so, enter the **auth-mode passcode resend-log** command.

```
Brocade(config-vlan-10-webauth)#auth-mode passcode resend-log
```

Syntax: **auth-mode passcode resend-log**

NOTE

The switch retransmits the current passcode only. Passcodes that are in the grace period are not sent.

Manually refreshing the passcode

You can manually refresh the passcode instead of waiting for the system to automatically generate one. When manually refreshed, the old passcode will no longer work, even if a grace period is configured. Also, if the passcode refresh method *duration of time* is used, the duration counter is reset when the passcode is manually refreshed. The passcode refresh method *time of day* is not affected when the passcode is manually refreshed.

To immediately refresh the passcode, enter the **auth-mode passcode generate** command.

```
Brocade(config-vlan-10-webauth)#auth-mode passcode generate
```

Syntax: **auth-mode passcode generate**

Automatic authentication

By default, if Web Authentication is enabled, hosts need to login and enter authentication credentials in order to gain access to the network. If a re-authentication period is configured, the host will be asked to re-enter authentication credentials once the re-authentication period ends.

You can configure Web Authentication to authenticate a host when the user presses the 'Login' button. When a host enters a valid URL address, Web Authentication checks the list of blocked MAC addresses. If the hosts' MAC address is not on the list and the number of allowable hosts has not been reached, after pressing the 'Login' button, the host is automatically authenticated for the duration of the configured re-authentication period, if one is configured. Once the re-authentication period ends, the host is logged out and needs to enter the URL address again.

NOTE

Automatic authentication is not the same as permanent authentication. (Refer to [“Specifying hosts that are permanently authenticated”](#) on page 1902). You must still specify devices that are to be permanently authenticated even if automatic authentication is enabled.

To enable automatic authentication, enter the following command.

```
Brocade(config)#vlan 10
Brocade(config-vlan-10)#webauth
Brocade(config-vlan-10-webauth)#auth-mode none
```

Syntax: **[no] auth-mode none**

If automatic authentication is enabled and a host address is not in the blocked MAC address list, Web Authentication authenticates the host and displays the Login page without user credentials, then provides a hyperlink to the requested URL site..

To determine if automatic authentication is enabled on your device, issue the **show webauth vlan <vlan-id>** command at the VLAN configuration level.

Syslog messages are generated under the following conditions:

- The feature is enabled
- The feature is disabled
- A MAC address is successfully authenticated
- Automatic authentication cannot occur because the maximum number of hosts allowed has been reached

Web authentication options configuration

The sections below explain other configuration options for Web Authentication.

Enabling RADIUS accounting for web authentication

When Web Authentication is enabled, you can enable RADIUS accounting to record login (start) and logout (stop) events per host. The information is sent to a RADIUS server. Note that packet/byte count is not supported.

To enable RADIUS accounting, enter the **accounting** command.

```
Brocade(config-vlan-10-webauth)#accounting
```

Syntax: [no] **accounting**

Enter the **no accounting** command to disable RADIUS accounting for Web Authentication.

Changing the login mode (HTTPS or HTTP)

Web Authentication can be configured to use secure (HTTPS) or non-secure (HTTP) login and logout pages. By default, HTTPS is used. [Figure 202](#) shows an example Login page.

To change the login mode to non-secure (HTTP), enter the **no secure-login** command.

```
Brocade(config-vlan-10-webauth)#no secure-login
```

To revert back to secure mode, enter the **secure-login** command.

```
Brocade(config-vlan-10-webauth)#secure-login
```

Syntax: [no] **secure-login**

Specifying trusted ports

You can configure certain ports of a Web Authentication VLAN as trusted ports. All hosts connected to the trusted ports need not authenticate and are automatically allowed access to the network.

To create a list of trusted ports, enter commands such as the following.

```
Brocade(config-vlan-10-webauth)#trust-port ethernet 3
Brocade(config-vlan-10-webauth)#trust port ethernet 6 to 10
```

The above commands configure ports 3 and 6 – 10 as trusted ports.

Syntax: `trust-port ethernet <port> [to <port>]`

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Specifying hosts that are permanently authenticated

Certain hosts, such as DHCP server, gateway, printers, may need to be permanently authenticated. Typically, these hosts are managed by the network administrator and are considered to be authorized hosts. Also, some of these hosts (such as printers) may not have a Web browser and will not be able to perform the Web Authentication.

To permanently authenticate these types of hosts, enter a command such as the following at the "webauth" configuration level.

```
Brocade(config-vlan-10-webauth)#add mac 0004.80eb.2d14 duration 0
Brocade(config-vlan-10-webauth)#add mac 0007.e90e.de3b duration 0
```

Syntax: `[no] add mac <mac-address> duration <seconds> | ethernet <port> duration <seconds>`

Syntax: `no add mac <mac-address>`

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

<seconds> specifies how long the MAC address remains authenticated. Enter 0 – 128000 seconds. The default is the current value of **reauth-time**. A value of "0" means that Web Authentication for the MAC address will not expire.

Instead of just entering a duration for how long the MAC address remains authenticated, you can specify the MAC address to be added by the specified port that is a member of the VLAN. To do this, enter values for the **ethernet <port> duration <seconds>** option. Enter the port number and the number of seconds the MAC address remains authenticated.

Entering a **no add mac <mac-address> duration <seconds> | ethernet <port> duration <seconds>** command sets duration and ethernet to their default values. If you want to remove a host, enter the **no add mac <mac-address>** command.

NOTE

If a MAC address is statically configured, this MAC address will not be allowed to be dynamically configured on any port.

Configuring the re-authentication period

After a successful authentication, a user remains authenticated for a duration of time. At the end of this duration, the host is automatically logged off. The user must be re-authenticated again. To set the number of seconds a host remains authenticated before being logged off, enter a command such as the following.

```
Brocade(config-vlan-10-webauth)#reauth-time 10
```

Syntax: [no] **reauth-time** <seconds>

You can specify 0 – 128000 seconds. The default is 28800 seconds, and 0 means the user is always authenticated and will never have to re-authenticate, except if an inactive period less than the re-authentication period is configured on the Web Authentication VLAN. If this is the case, the user becomes de-authenticated if there is no activity and the timer for the inactive period expires.

Defining the web authentication cycle

You can set a limit as to how many seconds users have to be Web Authenticated by defining a cycle time. This time begins at a user first Login attempt on the Login page. If the user has not been authenticated successfully when this time expires, the user must enter a valid URL again to display the Web Authentication Welcome page.

To define a cycle time, enter a command such as the following.

```
Brocade(config-vlan-10-webauth)#cycle time 20
```

Syntax: [no] **cycle time** <seconds>

Enter 0 – 3600 seconds, where 0 means there is no time limit. The default is 600 seconds

Limiting the number of web authentication attempts

You can set a limit on the number of times a user enters an invalid user name and password during the specified cycle time. If the user exceeds the limit, the user is blocked for a duration of time, which is defined by the **block duration** command. Also, the Web browser will be redirected to the Exceeded Allowable Attempts webpage.

To limit the number of Web Authentication attempts, enter a command such as the following.

```
Brocade(config-vlan-10-webauth)#attempt-max-num 4
```

Syntax: [no] **attempt-max-num** <number>

Enter a number from 0 to 64, where 0 means there is no limit to the number of Web Authentication attempts. The default is 5.

Clearing authenticated hosts from the web authentication table

Use the following commands to clear dynamically-authenticated hosts from the Web Authentication table.

To clear all authenticated hosts in a Web authentication VLAN, enter a command such as the following.

```
Brocade#clear webauth vlan 25 authenticated-mac
```

This command clears all the authenticated hosts in VLAN 25.

To clear a particular host in a Web authentication VLAN, enter a command such as the following.

```
Brocade#clear webauth vlan 25 authenticated-mac 1111.2222.3333
```

This command clears host 1111.2222.3333 from VLAN 25.

Syntax: `clear webauth vlan <vlan-id> authenticated-mac [<mac-address>]`

Setting and clearing the block duration for web authentication attempts

After users exceed the limit for Web Authentication attempts, specify how many seconds users must wait before the next cycle of Web Authenticated begins. Enter a command such as the following.

```
Brocade(config-vlan-10-webauth)#block duration 4
```

Syntax: `[no] block duration <seconds>`

Users cannot attempt Web Authentication during this time.

Enter 0–128000 seconds. The default is 90 seconds, and entering 0 means that the MAC address is infinitely blocked.

To unblock the MAC address, wait until the block duration timer expires or enter a command such as the following.

```
Brocade(config-vlan-10-webauth)#clear webauth vlan 10 block-mac 000.000.1234
```

Syntax: `clear webauth vlan <vlan-id> block-mac [<mac-address>]`

If you do not enter a `<mac-address>`, then all the entries for the specified VLAN will be cleared.

Manually blocking and unblocking a specific host

A host can be temporarily or permanently blocked from attempting Web Authentication by entering a command such as the following.

```
Brocade(config-vlan-10-webauth)#block mac 0123.17d1.0a3d duration 4
```

Syntax: `[no] block mac <mac-address> duration <seconds>`

Syntax: `no block mac <mac-address>`

Enter 0 – 128000 for `<seconds>`. The default is the current value of **block duration** command. Entering a value of "0" means the MAC address is blocked permanently.

Entering **no block mac <mac-address> duration <seconds>** resets duration to its default value.

You can unblock a host by entering the **no block mac <mac-address>** command.

Limiting the number of authenticated hosts

You can limit the number of hosts that are authenticated at any one time by entering a command such as the following.

```
Brocade(config-vlan-10-webauth)#host-max-num 300
```

Syntax: [no] **host-max-num** <number>

You can enter 0 – 8192, where 0 means there is no limit to the number of hosts that can be authenticated. The default is 0. The maximum is 8192 or the maximum number of MAC addresses the device supports.

When the maximum number of hosts has been reached, the FastIron switch redirects any new host that has been authenticated successfully to the Maximum Host webpage.

Filtering DNS queries

Many of the Web Authentication solutions allow DNS queries to be forwarded from unauthenticated hosts. To eliminate the threat of forwarding DNS queries from unauthenticated hosts to unknown or untrusted servers (also known as domain-casting), you can restrict DNS queries from unauthenticated hosts to be forwarded explicitly to defined servers by defining DNS filters. Any DNS query from an unauthenticated host to a server that is not defined in a DNS filter are dropped. Only DNS queries from unauthenticated hosts are affected by DNS filters; authenticated hosts are not. If the DNS filters are not defined, then any DNS queries can be made to any server.

You can have up to four DNS filters. Create a filter by entering the following command.

```
Brocade(config-vlan-10-webauth)#dns-filter 1 191.166.2.44/24
```

Syntax: [no] **dns-filter** <number> <ip-address> <subnet-mask> | <wildcard>

For <number>, enter a number from 1 to 4 to identify the DNS filter.

Enter the IP address and subnet mask of unauthenticated hosts that will be forwarded to the unknown/untrusted servers. Use the <ip-address> <subnet-mask> or <ip-address>/<subnet-mask> format.

You can use a <wildcard> for the filter. The <wildcard> is in dotted-decimal notation (IP address format). It is a four-part value, where each part is 8 bits (one byte) separated by dots, and each bit is a one or a zero. Each part is a number ranging from 0 to 255, for example 0.0.0.255. Zeros in the mask mean the packet source address must match the IP address. Ones mean any value matches. For example, the <ip-address> and <subnet-mask> values 209.157.22.26 0.0.0.255 mean that all hosts in the Class C sub-net 209.157.22.x match the policy.

Forcing re-authentication when ports are down

If all ports on the device go down, you may want to force all authenticated hosts to be re-authenticated. You can do this by entering the **port-down-auth-mac-cleanup** command.

```
Brocade(config-vlan-10-webauth)#port-down-auth-mac-cleanup
```

Syntax: [no] **port-down-auth-mac-cleanup**

While this command is enabled, the device checks the link state of all ports that are members of the Web Authentication VLAN. If the state of all the ports is down, then the device forces all authenticated hosts to re-authenticate. However, hosts that were authenticated using the add mac command will remain authenticated; they are not affected by the **port-down-auth-mac-cleanup** command.

Forcing re-authentication after an inactive period

You can force Web Authenticated hosts to be re-authenticated if they have been inactive for a period of time. The inactive duration is calculated by adding the `mac-age-time` that has been configured for the device and the configured **authenticated-mac-age-time**. (The **mac-age-time** command defines how long a port address remains active in the address table.) If the authenticated host is inactive for the sum of these two values, the host is forced to be re-authenticated.

To force authenticated hosts to re-authenticate after a period of inactivity, enter commands such as the following.

```
Brocade(config)#mac-age-time 600
Brocade(config)#vlan 23
Brocade(config-vlan-23)webauth
Brocade(config-vlan-23-webauth)#reauth-time 303
Brocade(config-vlan-23-webauth)#authenticated-mac-age-time 300
```

Syntax: `[no] authenticated-mac-age-time <seconds>`

You can enter a value from 0 to the value entered for **reauth-time**. The default is 3600.

Refer to [“Changing the MAC age time and disabling MAC address learning”](#) on page 560 for details on the **mac-age-time** command. The default **mac-age-time** is 300 seconds and can be configured to be between 60 and 600 on the FastIron switch. If it is configured to be 0, then the MAC address does not age out due to inactivity.

Defining the web authorization redirect address

When a user enters a valid URL address (one that exists), the user is redirected to a Web Authentication address and the Welcome page for Web Authentication is displayed. By default, this Web Authentication address is the IP address of the FastIron switch. You can change this address so that the address matches the name on the security certificates.

To change the address on a Layer 2 switch, enter a command such as the following at the global configuration level.

```
Brocade(config)#webauth-redirect-address my.domain.net
```

To change the address on a Layer 3 switch, enter a command such as the following at the Web Authentication VLAN level.

```
Brocade(config-vlan-10-webauth)#webauth-redirect-address my.domain.net
```

Entering "my.domain.net" redirects the browser to `https://my.domain.net/` when the user enters a valid URL on the Web browser.

Syntax: `[no] webauth-redirect-address <string>`

For `<string>`, enter up to 64 alphanumeric characters. You can enter any value for `<string>`, but entering the name on the security certificate prevents the display of error messages saying that the security certificate does not match the name of the site.

Deleting a web authentication VLAN

To delete a Web Authentication VLAN, enter the following commands:

```
Brocade(config)#vlan 10  
Brocade(config-vlan-10)no webauth
```

Syntax: no webauth

Web authentication pages

There are several pages that can be displayed for Web Authentication.

When a user first enters a valid URL address on the Web browser, the browser is redirected to the Web Authentication URL (refer to [“Defining the web authorization redirect address”](#) on page 1906).

If Automatic Authentication is enabled, the following Welcome page appears:

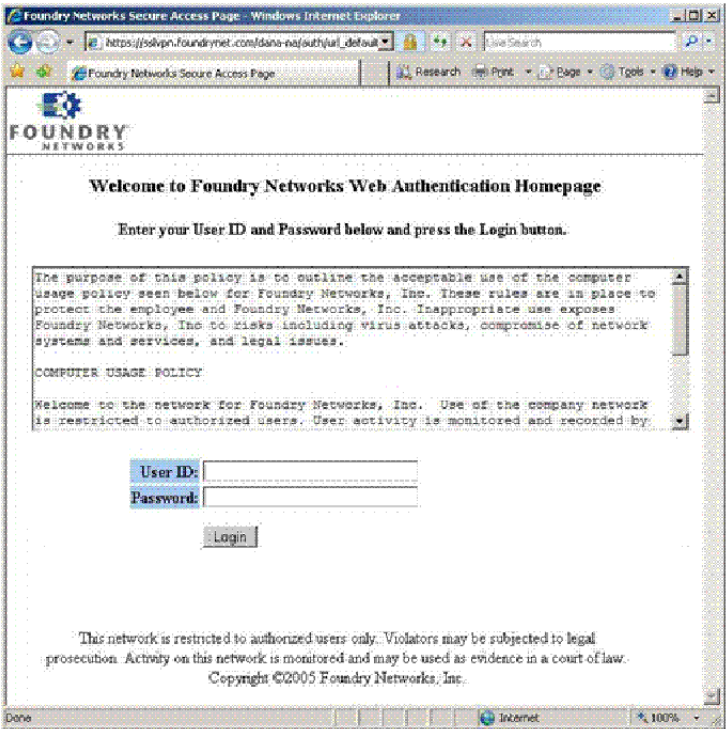

FIGURE 201 Example of a welcome page when automatic authentication is enabled

The browser will then be directed to the requested URL.

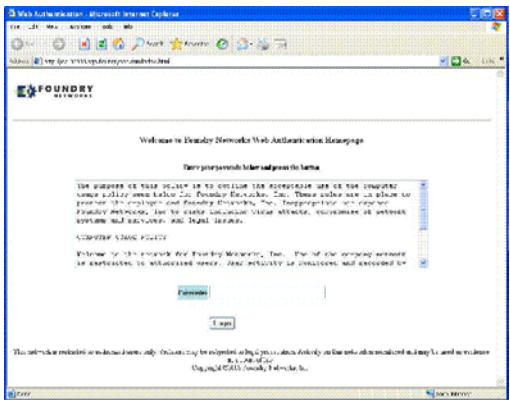

If username and password (Local User Database) authentication is enabled, the following Login page appears.

FIGURE 202 Example of a login page when automatic authentication is disabled and local user database is enabled

The user enters a user name and password, which are then sent for authentication.
If passcode authentication is enabled, the following Login page appears.

FIGURE 203 Example of a login page when automatic authentication is disabled and passcode Authentication is Enabled

The user enters a passcode, which is then sent for authentication.
If the Web Authentication fails, the page to try again is displayed (Figure 204).

FIGURE 204 Example of a try again page

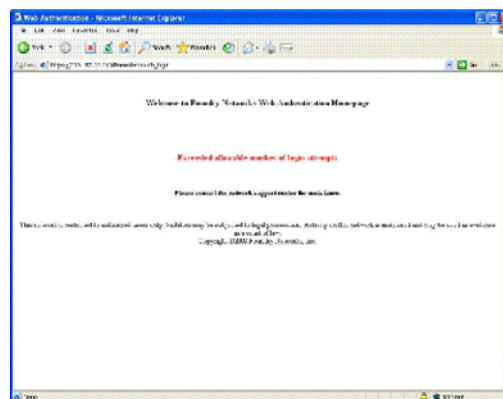

If the limit for the number of authenticated users on the network is exceeded, the Maximum Host Limit page is displayed (Figure 205).

FIGURE 205 Example of a maximum Host limit page

If the number of Web Authentication attempts by a user has been exceeded, the Maximum Attempts Limit page is displayed (Figure 206). The user is blocked from attempting any Web Authentication unless either the user MAC address is removed from the blocked list (using the **clear webauth block-mac <mac-address>** command) or when the block duration timer expires.

FIGURE 206 Example of a maximum attempts limit page

If the user Web Authentication attempt is successful, the Success page is displayed (Figure 207).

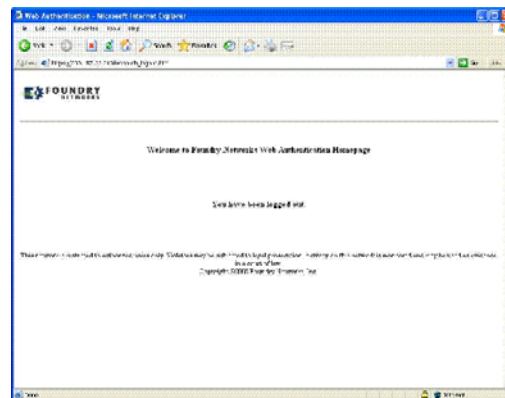

FIGURE 207 Example of a web authentication success page

Once a host is authenticated, that host can manually de-authenticate by clicking the **Logout** button in the Login Success page. The host remains logged in until the re-authentication period expires. At that time, the host is automatically logged out. However, if a re-authentication period is not configured, then the host remains logged in indefinitely.

NOTE

If you accidentally close the Success page, you will not be able to log out. If a re-authentication period is configured, you will be logged out once the re-authentication period ends.

The host can log out of the Web session by simply clicking the Logout button. Once logged out, the following window appears.

You can customize the top and bottom text for the all of the windows shown in [Figure 201](#) through [Figure 207](#).

Displaying text for web authentication pages

Use the **show webauth vlan <vlan-ID> webpage** command to determine what text has been configured for Web Authentication pages.

```
Brocade#show webauth vlan 25 webpage
=====
Web Page Customizations (VLAN 25):
  Top (Header): Default Text
    "<h3>Welcome to Brocade Communications, Inc. Web Authentication
Homepage</h3>"
  Bottom (Footer): Custom Text
    "Copyright 2009 SNL"
  Title: Default Text
    "Web Authentication"
  Login Button: Custom Text
    "Sign On"
  Web Page Logo: blogo.gif
    align: left (Default)
  Web Page Terms and Conditions: policy1.txt
```

Syntax: **show webauth vlan <vlan-id> webpage**

Customizing web authentication pages

You can customize the following objects in the Web Authentication pages shown in [Figure 201](#) through [Figure 207](#):

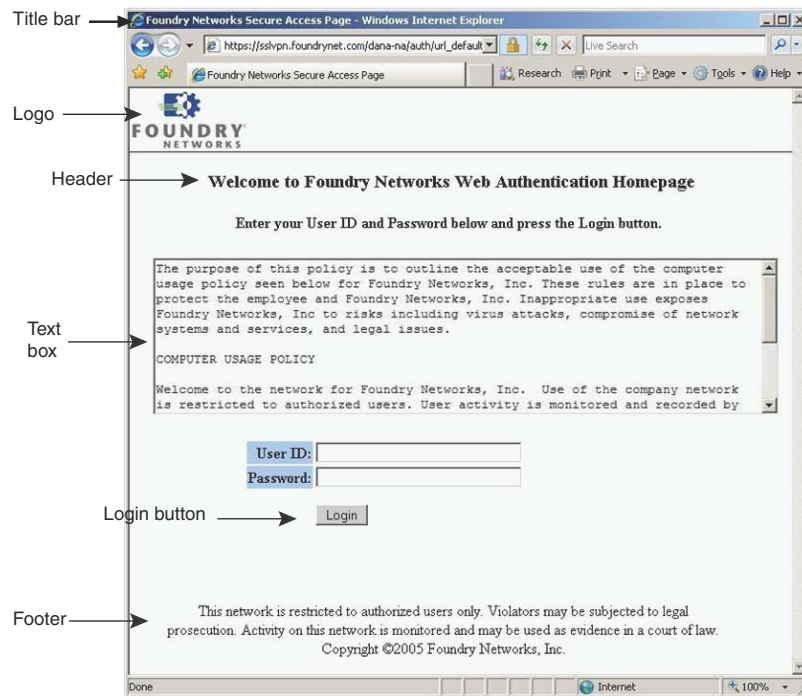

- Title bar
- Banner image (the logo)
- Header
- Text box
- Login button
- Footer

You can use the CLI commands **show webauth** and **show webauth vlan <vlan-id> webpage** to determine what text has been configured for Web Authentication pages.

NOTE

The banner image does not apply to the Web Authentication Maximum Attempts Limit page ([Figure 206](#)). The text box and Login button apply to the Login page only.

[Figure 208](#) shows the placement of these objects in the Login page.

FIGURE 208 Objects in the web authentication pages that can be customized

Customizing the title bar

You can customize the title bar that appears on all Web Authentication pages (refer to [Figure 208](#)). To do so, enter a command such as the following.

```
Brocade(config-vlan-10-webauth)#webpage custom-text title "Brocade Secure Access Page"
```

Syntax: [no] webpage custom-text title "<title>"

For <title>, enter up to 128 alphanumeric characters. The default title bar is "Web Authentication".

To reset the title bar back to the default value, enter the command **no webpage custom-text title**.

Customizing the banner image (Logo)

You can customize the logo that appears on all Web Authentication pages. [Figure 208](#) shows placement of the banner image in the Login page.

NOTE

The banner image does not display in the Maximum Attempts Limit page ([Figure 206](#)).

To customize the banner image, use the TFTP protocol to upload an image file from a TFTP server to the FastIron switch. The image file can be in the format jpg, bmp, or gif, and its size must be 64K or less. When you upload a new image file, it will overwrite the existing image file.

To replace the existing logo with a new one, enter a command such as the following.

```
Brocade(config-vlan-10-webauth)#webpage logo copy tftp 10.10.5.1 brocadelogo.gif
```

Syntax: [no] webpage logo copy tftp <ip-address> <filename>

NOTE

This command downloads the image file and stores it in the device flash memory. Therefore, it is not necessary to follow this command with a **write memory**.

The `<ip-address>` parameter specifies the address of the TFTP server on which the image file resides.

The `<filename>` parameter specifies the name of the image file on the TFTP server.

Use the `no webpage logo` command to delete the logo from all Web Authentication pages and remove it from flash memory.

Aligning the banner image (Logo)

You can optionally configure the placement of the logo that appears on all Web Authentication pages (refer to [Figure 208](#)). By default, the logo is left-aligned at the top of the page. To center the logo at the top of the page, enter the following command.

```
Brocade(config-vlan-10-webauth)#webpage logo align center
```

To right-justify the log at the top of the page, enter the following command.

```
Brocade(config-vlan-10-webauth)#webpage logo align right
```

Syntax: `[no] webpage logo align center | left | right`

Use the `no webpage logo align` command to reset the logo back to its default position (left).

Customizing the header

You can customize the header that appears on all Web Authentication pages. [Figure 208](#) shows placement of the header in the Login page.

To customize the header, enter a command such as the following.

```
Brocade(config-vlan-10-webauth)#webpage custom-text top "Welcome to Network One"
```

Syntax: `[no] webpage custom-text top <text>`

For `<text>`, enter up to 255 alphanumeric characters.

To reset the header back to the default text, enter the command `no webpage custom-text top`. The default text is "Welcome to Brocade Communications, Inc. Web Authentication Homepage".

Customizing the text box

You can customize the text box that appears on the Web Authentication Login page. [Figure 208](#) shows placement of the text box in the Login page. By default, the text box is empty and is not visible. To create a text box or to replace the existing one, upload an ASCII text file from a TFTP server to the FastIron switch. The text file size must not exceed 2K.

To create or replace a text box, enter a command such as the following.

```
Brocade(config-vlan-10-webauth)#webpage terms copy tftp 10.10.5.1 policy.txt
```

Syntax: `[no] webpage terms copy tftp <ip-address> <filename>`

NOTE

This command downloads the text file and stores it in the device flash memory. Therefore, it is not necessary to follow this command with a **write memory**.

The `<ip-address>` parameter is the address of the TFTP server on which the image resides.

The `<filename>` parameter is the name of the text file on the TFTP server.

To revert back to the default text box (none), enter the command **no webpage terms**.

Customizing the login button

You can customize the Login button that appears on the bottom of the Web Authentication Login page (refer to [Figure 208](#)). To do so, enter a command such as the following.

```
Brocade(config-vlan-10-webauth)#webpage custom-text login-button "Press to Log In"
```

Syntax: `[no] webpage custom-text login-button "<text>"`

For `<text>`, enter up to 32 alphanumeric characters.

To reset the Login button back to the default value ("Login"), enter the command **no webpage custom-text login-button**.

Customizing the footer

You can customize the footer that appears on all Web Authentication pages. [Figure 208](#) shows placement of the footer in the Login page.

To customize the footer enter a command such as the following.

```
Brocade(config-vlan-10-webauth)#webpage custom-text bottom "Network One Copyright 2010"
```

Syntax: `[no] webpage custom-text bottom "<text>"`

For `<text>`, enter up to 255 alphanumeric characters.

To reset the footer back to the default text, enter the command **no webpage custom-text bottom**. The default text is "This network is restricted to authorized users only. Violators may be subjected to legal prosecution. Activity on this network is monitored and may be used as evidence in a court of law. Copyright 2009 Brocade Communications, Inc., Inc."

Displaying web authentication information

The following sections present the **show** commands you can use to display information about the Web Authentication feature.

Displaying the web authentication configuration

Enter the **show webauth** command to display the configuration for the Web Authentication feature.

```
Brocade#show webauth
```

```
=====
WEB AUTHENTICATION (VLAN 25): Enable
attempt-max-num: 5 (Default)
host-max-num: 0 (Default)
block duration: 90 (Default)
cycle-time: 600 (Default)
port-down-authenticated-mac-cleanup: Enable (Default)
reauth-time: 28800 (Default)
```

Displaying web authentication information

```
authenticated-mac-age-time: 3600 (Default)
dns-filter: Disable (Default)
authentication mode: username and password (Default)
  authentication methods: radius
    Local user database name: <none>
Radius accounting: Enable (Default)
Trusted port list: None
Secure Login (HTTPS): Enable (Default)
Web Page Customizations:
  Top (Header): Default Text
  Bottom (Footer): Custom Text
    "SNL Copyright 2009"
  Title: Default Text
  Login Button: Custom Text
    "Sign On"
  Web Page Logo: blogo.gif
    align: left (Default)
  Web Page Terms and Conditions: policy1.txt
Host statistics:
  Number of hosts dynamically authenticated: 0
  Number of hosts statically authenticated: 2
  Number of hosts dynamically blocked: 0
  Number of hosts statically blocked: 0
  Number of hosts authenticating: 1
```

The **show webauth** command displays the following information.

Field	Description
WEB AUTHENTICATION (VLAN 10)	Identifies the VLAN on which Web Authentication is enabled.
attempt-max-num	The maximum number of Web Authentication attempts during a cycle.
host-max-num	The maximum number of users that can be authenticated at one time.
block duration	How many seconds a user who failed Web Authentication must wait before attempting to be authenticated.
cycle-time	The number of seconds in one Web Authentication cycle.
port-down-authenticated-mac-cleanup	Indicates if this option is enabled or disabled. If enabled, all authenticated users are de-authenticated if all the ports in the VLAN go down.
reauth-time	The number of seconds an authenticated user remains authenticated. Once this timer expires, the user must re-authenticate.
authenticated-mac-age-time	If a user is inactive, this time shows how many seconds a user has before the user associated MAC address is aged out. The user will be forced to re-authenticate.
dns-filter	Shows the definition of any DNS filter that have been set. (Refer to "Filtering DNS queries" on page 1905)
authentication mode	The authentication mode: <ul style="list-style-type: none">• username and password (default)• passcode• none Also displays configuration details for the authentication mode.
RADIUS accounting	Whether RADIUS accounting is enabled or disabled.

Field	Description
Trusted port list	The statically-configured trusted ports of the Web Authentication VLAN.
Secure login (HTTPS)	Whether HTTPS is enabled or disabled.
Web Page Customizations	<p>The current configuration for the text that appears on the Web Authentication pages. Either "Custom Text" or "Default Text" displays for each page type:</p> <ul style="list-style-type: none"> "Custom Text" means the message for the page has been customized. The custom text is also displayed. "Default Text" means the default message that ships with the FastIron switch is used. <p>The actual text on the Web Authentication pages can be displayed using the show webauth vlan <vlan-id> webpage command. Refer to "Displaying text for web authentication pages" on page 1912.</p>
Host statistics	The authentication status and the number of hosts in each state.

Syntax: **show webauth** [vlan <vlan-id>]

The show webauth command by itself displays information for all VLANs on which Web Authentication is enabled. Use the vlan <vlan-id> parameter to display information for a specific VLAN.

Displaying a list of authenticated hosts

Enter the **show webauth allowed-list** command to display a list of hosts that are currently authenticated.

```

Brocade#show webauth allowed-list
=====
VLAN 1: Web Authentication
-----
Web Authenticated List      Configuration      Authenticated Duration Remaining
MAC Address      User Name      Static/Dynamic      HH:MM:SS
-----
00a0.f86c.2807      N/A            D                    00:03:05
0009.5b69.79ea      fdry1          D                    04:58:01
000c.db82.8bca      N/A            S                    Infinite
0007.e90e.de3b      N/A            S                    Infinite
000a.e442.a50e      fdry2          D                    00:25:25
    
```

The displays shows the following information.

Field	Description
VLAN #: Web Authentication	The ID of the VLAN on which Web Authentication is enabled.
Web Authenticated List MAC Address	The MAC addresses that have been authenticated.
User Name	The authenticated username.
Configuration Static/Dynamic	If the MAC address was dynamically (passed Web Authentication) or statically (added to the authenticated list using the add mac command) authenticated.
Authenticated Duration	The remainder of time the MAC address will remain authenticated

Syntax: show webauth allowed-list

Displaying a list of hosts attempting to authenticate

Enter the **show webauth authenticating-list** command to display a list of hosts that are trying to authenticate.

```
Brocade#show webauth authenticating-list
=====
VLAN 25: Web Authentication
-----
Web Authenticating List          # of Failed   Cycle Time
Remaining
MAC Address      User Name          Attempts      HH:MM:SS
-----
0012.3ff9.1fc6  N/A                      0             00:09:46
```

The report shows the following information.

This field...	Displays...
VLAN #: Web Authentication	The ID of the VLAN on which Web Authentication is enabled.
MAC Address	The MAC addresses that are trying to be authenticated.
User Name	The User Name associated with the MAC address.
# of Failed Attempts	Number of authentication attempts that have failed.
Cycle Time Remaining	The remaining time the user has to be authenticated before the current authentication cycle expires. Once it expires, the user must enter a valid URL again to display the Web Authentication Welcome page.

Syntax: show webauth authenticating-list

Displaying a list of blocked hosts

Enter the **show webauth blocked-list** command to display a list of hosts that are currently blocked from any Web Authentication Attempt.

```
Brocade#show webauth blocked-list
=====
VLAN 1: Web Authentication
-----
Web Block List          Configuration      Block Duration Remaining
MAC Address            User Name        Static/Dynamic      HH:MM:SS
-----
0009.a213.ff09         bauser           S                    00:31:27
00a0.f86c.2807         causer           D                    00:01:24
00a0.f890.1ab3         dauser           S                    infinite
```

The report shows the following information.

Field	Description
VLAN #: Web Authentication	The ID of the VLAN on which Web Authentication is enabled.
Web Block List MAC Address	The MAC addresses that have been blocked from Web Authentication.
User Name	The User Name associated with the MAC address.
Configuration Static/Dynamic	If the MAC address was dynamically or statically blocked. The block mac command statically blocks MAC addresses.
Block Duration Remaining	The remaining time the MAC address has before the user with that MAC address can attempt Web Authentication.

Syntax: show webauth blocked-list

Displaying a list of local user databases

The **show local-userdb** command displays a list of all local user databases configured on the FastIron switch and the number of users in each database.

```
Brocade#show local-userdb
=====
Local User Database Name      : My_Database
Number of users in the database : 4
=====
Local User Database Name      : test
Number of users in the database : 3
=====
Local User Database Name      : test123
Number of users in the database : 3
```

Syntax: show local-userdb

Displaying a list of users in a local user database

The **show local-userdb test** command displays a list of all users in a particular local user database.

```
Brocade#show local-userdb test

=====
Local User Database : test
Username                Password
-----                -
user1                   $e$&Z9'%'*%+
user2                   $e$, )A= )65N,%-3*%1?@U
user3                   $e$5%&-5%YO&&A1%6%<@U
```

As shown in the above example, passwords are encrypted in the command output.

Syntax: show local-userdb <db-name>

Displaying passcodes

If the *passcode* Web authentication mode is enabled, you can use the following command to display current passcodes.

```
Brocade#show webauth vlan 25 passcode
Current Passcode : 1389
This passcode is valid for 35089 seconds
```

Syntax: show webauth vlan <vlan-id> passcode

DoS Attack Protection

Table 316 lists individual Brocade switches and the DoS protection features they support. These features are supported in the Layer 2, base Layer 3, edge Layer 3, and full Layer 3 software images, except where noted.

TABLE 316 Supported DoS protection features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
Smurf attack (ICMP attack) protection	Yes	Yes	Yes	Yes	Yes
TCP SYN attack protection	Yes	Yes	Yes	Yes	Yes

This chapter explains how to protect your Brocade devices from Denial of Service (DoS) attacks.

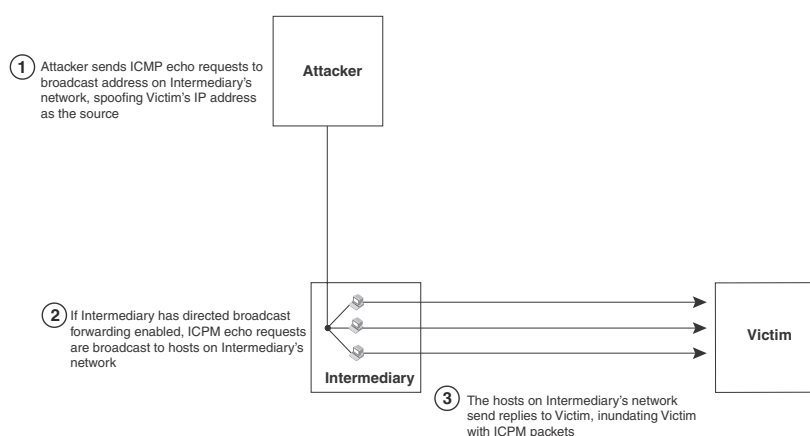

In a Denial of Service (DoS) attack, a router is flooded with useless packets, hindering normal operation. Brocade devices include measures for defending against two types of DoS attacks: Smurf attacks and TCP SYN attacks.

Smurf attacks

A *Smurf attack* is a kind of DoS attack in which an attacker causes a victim to be flooded with Internet Control Message Protocol (ICMP) echo (Ping) replies sent from another network.

Figure 209 illustrates how a Smurf attack works.

FIGURE 209 How a Smurf attack floods a victim with ICMP replies

The attacker sends an ICMP echo request packet to the broadcast address of an intermediary network. The ICMP echo request packet contains the spoofed address of a victim network as its source. When the ICMP echo request reaches the intermediary network, it is converted to a Layer 2 broadcast and sent to the hosts on the intermediary network. The hosts on the intermediary network then send ICMP replies to the victim network.

For each ICMP echo request packet sent by the attacker, a number of ICMP replies equal to the number of hosts on the intermediary network are sent to the victim. If the attacker generates a large volume of ICMP echo request packets, and the intermediary network contains a large number of hosts, the victim can be overwhelmed with ICMP replies.

Avoiding being an intermediary in a Smurf attack

A Smurf attack relies on the intermediary to broadcast ICMP echo request packets to hosts on a target subnet. When the ICMP echo request packet arrives at the target subnet, it is converted to a Layer 2 broadcast and sent to the connected hosts. This conversion takes place only when directed broadcast forwarding is enabled on the device.

To avoid being an intermediary in a Smurf attack, make sure forwarding of directed broadcasts is disabled on the Brocade device. Directed broadcast forwarding is disabled by default. To disable directed broadcast forwarding, do one of the following.

```
Brocade(config)#no ip directed-broadcast
```

Syntax: [no] ip directed-broadcast

Avoiding being a victim in a Smurf attack

You can configure the Brocade device to drop ICMP packets when excessive numbers are encountered, as is the case when the device is the victim of a Smurf attack. You can set threshold values for ICMP packets that are targeted at the router itself or passing through an interface, and drop them when the thresholds are exceeded.

For example, to set threshold values for ICMP packets targeted at the router, enter the following command in global CONFIG mode.

```
Brocade(config)#ip icmp burst-normal 5000 burst-max 10000 lockup 300
```

To set threshold values for ICMP packets received on interface 3/11, enter the following commands.

```
Brocade(config)#interface ethernet 3/11
Brocade(config-if-e1000-3/11)#ip icmp burst-normal 5000 burst-max 10000 lockup 300
```

For Layer 3 router code, if the interface is part of a VLAN that has a router VE, you must configure ICMP attack protection at the VE level. Otherwise, you can configure this feature at the interface level as shown in the previous example. When ICMP attack protection is configured at the VE level, it will apply to routed traffic only. It will not affect switched traffic.

NOTE

You must configure VLAN information for the port *before* configuring ICMP attack protection. You cannot change the VLAN configuration for a port on which ICMP attack protection is enabled.

To set threshold values for ICMP packets received on VE 31, enter commands such as the following.

```
Brocade(config)#interface ve 31
Brocade(config-vif-31)#ip icmp burst-normal 5000 burst-max 10000 lockup 300
```

Syntax: `ip icmp burst-normal <value> burst-max <value> lockup <seconds>`

The **burst-normal** <value> parameter can be from 1 through 100,000 packets per second.

The **burst-max** <value> parameter can be from 1 through 100,000 packets per second.

The **lockup** <value> parameter can be from 1 through 10,000 seconds.

This command is supported on Ethernet and Layer 3 interfaces.

The number of incoming ICMP packets per second is measured and compared to the threshold values as follows:

- If the number of ICMP packets exceeds the **burst-normal** value, the excess ICMP packets are dropped.
- If the number of ICMP packets exceeds the **burst-max** value, all ICMP packets are dropped for the number of seconds specified by the **lockup** value. When the lockup period expires, the packet counter is reset and measurement is restarted.

In the example, if the number of ICMP packets received per second exceeds 5,000, the excess packets are dropped. If the number of ICMP packets received per second exceeds 10,000, the device drops all ICMP packets for the next 300 seconds (5 minutes).

TCP SYN attacks

TCP SYN attacks exploit the process of how TCP connections are established to disrupt normal traffic flow. When a TCP connection starts, the connecting host first sends a TCP SYN packet to the destination host. The destination host responds with a SYN ACK packet, and the connecting host sends back an ACK packet. This process, known as a “TCP three-way handshake,” establishes the TCP connection.

While waiting for the connecting host to send an ACK packet, the destination host keeps track of the as-yet incomplete TCP connection in a connection queue. When the ACK packet is received, information about the connection is removed from the connection queue. Usually there is not much time between the destination host sending a SYN ACK packet and the source host sending an ACK packet, so the connection queue clears quickly.

In a TCP SYN attack, an attacker floods a host with TCP SYN packets that have random source IP addresses. For each of these TCP SYN packets, the destination host responds with a SYN ACK packet and adds information to the connection queue. However, because the source host does not exist, no ACK packet is sent back to the destination host, and an entry remains in the connection queue until it ages out (after approximately a minute). If the attacker sends enough TCP SYN packets, the connection queue can fill up, and service can be denied to legitimate TCP connections.

To protect against TCP SYN attacks, you can configure the Brocade device to drop TCP SYN packets when excessive numbers are encountered. You can set threshold values for TCP SYN packets that are targeted at the router itself or passing through an interface, and drop them when the thresholds are exceeded.

For example, to set threshold values for TCP SYN packets targeted at the router, enter the following command in global CONFIG mode.

```
Brocade(config)#ip tcp burst-normal 10 burst-max 100 lockup 300
```

To set threshold values for TCP SYN packets received on interface 3/11, enter the following commands.

```
Brocade(config)#interface ethernet 3/11
Brocade(config-if-e1000-3/11)#ip tcp burst-normal 10 burst-max 100 lockup 300
```

For Layer 3 router code, if the interface is part of a VLAN that has a router VE, you must configure TCP/SYN attack protection at the VE level. Otherwise, you can configure this feature at the interface level as shown in the previous example. When TCP/SYN attack protection is configured at the VE level, it will apply to routed traffic only. It will not affect switched traffic.

NOTE

You must configure VLAN information for the port *before* configuring TCP/SYN attack protection. You cannot change the VLAN configuration for a port on which TCP/SYN attack protection is enabled.

To set threshold values for TCP/SYN packets received on VE 31, enter commands such as the following.

```
Brocade(config)#interface ve 31
Brocade(config-vif-31)#ip tcp burst-normal 5000 burst-max 10000 lockup 300
```

Syntax: `ip tcp burst-normal <value> burst-max <value> lockup <seconds>`

NOTE

This command is available at the global CONFIG level on both Chassis devices and Compact devices. On Chassis devices, this command is available at the Interface level as well. This command is supported on Ethernet and Layer 3 interfaces.

The **burst-normal** <value> parameter can be from 1 – 100,000 packets per second.

The **burst-max** <value> parameter can be from 1 – 100,000 packets per second.

The **lockup** <value> parameter can be from 1 – 10,000 seconds.

The number of incoming TCP SYN packets per second is measured and compared to the threshold values as follows:

- If the number of TCP SYN packets exceeds the **burst-normal** value, the excess TCP SYN packets are dropped.
- If the number of TCP SYN packets exceeds the **burst-max** value, all TCP SYN packets are dropped for the number of seconds specified by the **lockup** value. When the lockup period expires, the packet counter is reset and measurement is restarted.

In the example, if the number of TCP SYN packets received per second exceeds 10, the excess packets are dropped. If the number of TCP SYN packets received per second exceeds 100, the device drops all TCP SYN packets for the next 300 seconds (5 minutes).

TCP security enhancement

TCP security enhancement improves upon the handling of TCP inbound segments. This enhancement eliminates or minimizes the possibility of a TCP reset attack, in which a perpetrator attempts to prematurely terminate an active TCP session, and a data injection attack, wherein an attacker injects or manipulates data in a TCP connection.

In both cases, the attack is blind, meaning the perpetrator does not have visibility into the content of the data stream between two devices, but blindly injects traffic. Also, the attacker does not see the direct effect, the continuing communications between the devices and the impact of the injected packet, but may see the indirect impact of a terminated or corrupted session.

The TCP security enhancement prevents and protects against the following three types of attacks:

- Blind TCP reset attack using the reset (RST) bit
- Blind TCP reset attack using the synchronization (SYN) bit
- Blind TCP packet injection attack

The TCP security enhancement is automatically enabled.

Protecting against a blind TCP reset attack using the RST bit

In a blind TCP reset attack using the RST bit, a perpetrator attempts to guess the RST bits to prematurely terminate an active TCP session.

To prevent a user from using the RST bit to reset a TCP connection, the RST bit is subject to the following rules when receiving TCP segments:

- If the RST bit is set and the sequence number is outside the expected window, the Brocade device silently drops the segment.
- If the RST bit is exactly the next expected sequence number, the Brocade device resets the connection.
- If the RST bit is set and the sequence number does not exactly match the next expected sequence value, but is within the acceptable window, the Brocade device sends an acknowledgement.

Protecting against a blind TCP reset attack using the SYN bit

In a blind TCP reset attack using the SYN bit, a perpetrator attempts to guess the SYN bits to prematurely terminate an active TCP session.

To prevent a user from using the SYN bit to tear down a TCP connection, in current software releases, the SYN bit is subject to the following rules when receiving TCP segments:

- If the SYN bit is set and the sequence number is outside the expected window, the Brocade device sends an acknowledgement (ACK) back to the peer.
- If the SYN bit is set and the sequence number is an exact match to the next expected sequence, the Brocade device sends an ACK segment to the peer. Before sending the ACK segment, the software subtracts one from the value being acknowledged.
- If the SYN bit is set and the sequence number is acceptable, the Brocade device sends an acknowledgement (ACK) segment to the peer.

Protecting against a blind injection attack

In a blind TCP injection attack, a perpetrator tries to inject or manipulate data in a TCP connection.

To reduce the chances of a blind injection attack, an additional check on all incoming TCP segments is performed.

Displaying statistics about packets dropped because of DoS attacks

To display information about ICMP and TCP SYN packets dropped because burst thresholds were exceeded, enter the **show statistics dos-attack** command.

```
Brocade#show statistics dos-attack
----- Local Attack Statistics -----
ICMP Drop Count      ICMP Block Count      SYN Drop Count      SYN Block Count
-----
0                    0                    0                    0
-----
----- Transit Attack Statistics -----
Port    ICMP Drop Count      ICMP Block Count      SYN Drop Count      SYN Block Count
-----
3/11    0                    0                    0                    0
```

Syntax: **show statistics dos-attack**

To clear statistics about ICMP and TCP SYN packets dropped because burst thresholds were exceeded, enter the **clear statistics dos-attack** command.

```
Brocade#clear statistics dos-attack
```

Syntax: **clear statistics dos-attack**

DHCP

[Table 317](#) lists individual Brocade switches and the Dynamic Host Configuration Protocol (DHCP) packet inspection and tracking features they support. These features are supported in the Layer 2, base Layer 3, edge Layer 3, and full Layer 3 software images, except where explicitly noted.

TABLE 317 Supported DHCP packet inspection and tracking features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
Dynamic ARP inspection	Yes	Yes	Yes	Yes	Yes
DHCP snooping	Yes	Yes	Yes	Yes	Yes
DHCP relay agent information (DHCP Option 82)	Yes	Yes	Yes	Yes	Yes
IP source guard	Yes	Yes	Yes	Yes	Yes

Dynamic ARP inspection

For enhanced network security, you can configure the Brocade device to inspect and keep track of Dynamic Host Configuration Protocol (DHCP) assignments.

Dynamic ARP Inspection (DAI) enables the Brocade device to intercept and examine all ARP request and response packets in a subnet and discard those packets with invalid IP to MAC address bindings. DAI can prevent common man-in-the-middle (MiM) attacks such as ARP cache poisoning, and disallow mis-configuration of client IP addresses.

ARP poisoning

ARP provides IP communication within a Layer 2 broadcast domain by mapping an IP address to a MAC address. Before a host can talk to another host, it must map the IP address to a MAC address first. If the host does not have the mapping in its ARP table, it creates an ARP request to resolve the mapping. All computers on the subnet will receive and process the ARP requests, and the host whose IP address matches the IP address in the request will send an ARP reply.

An ARP poisoning attack can target hosts, switches, and routers connected to the Layer 2 network by poisoning the ARP caches of systems connected to the subnet and by intercepting traffic intended for other hosts on the subnet. For instance, a malicious host can reply to an ARP request with its own MAC address, thereby causing other hosts on the same subnet to store this information in their ARP tables or replace the existing ARP entry. Furthermore, a host can send gratuitous replies without having received any ARP requests. A malicious host can also send out ARP packets claiming to have an IP address that actually belongs to another host (e.g. the default router). After the attack, all traffic from the device under attack flows through the attacker computer and then to the router, switch, or host.

About Dynamic ARP Inspection

Dynamic ARP Inspection (DAI) allows only valid ARP requests and responses to be forwarded.

A Brocade device on which DAI is configured does the following:

- Intercepts ARP packets received by the system CPU
- Inspects all ARP requests and responses received on untrusted ports
- Verifies that each of the intercepted packets has a valid IP-to-MAC address binding before updating the local ARP table, or before forwarding the packet to the appropriate destination
- Drops invalid ARP packets

When you enable DAI on a VLAN, by default, all member ports are untrusted. You must manually configure trusted ports. In a typical network configuration, ports connected to host ports are untrusted. You configure ports connected to other switches or routers as trusted.

DAI inspects ARP packets received on untrusted ports, as shown in [Figure 210](#). DAI carries out the inspection based on IP-to-MAC address bindings stored in a trusted binding database. For the Brocade device, the binding database is the ARP table, which supports DAI, DHCP snooping, and IP Source Guard. To inspect an ARP request packet, DAI checks the source IP and source MAC address against the ARP table. For an ARP reply packet, DAI checks the source IP, source MAC, destination IP, and destination MAC addresses. DAI forwards the valid packets and discards those with invalid IP-to-MAC address bindings.

When ARP packets reach a trusted port, DAI lets them through, as shown in [Figure 210](#).

FIGURE 210 Dynamic ARP inspection at work

ARP entries

DAI uses the IP/MAC mappings in the ARP table to validate ARP packets received on untrusted ports.

ARP entries in the ARP table derive from the following:

- **Dynamic ARP** – normal ARP learned from trusted ports.
- **Static ARP** – statically configured IP/MAC/port mapping.
- **Inspection ARP** – statically configured IP/MAC mapping, where the port is initially unspecified. The actual physical port mapping will be resolved and updated from validated ARP packets. Refer to [“Configuring an inspection ARP entry”](#) on page 1930.

- **DHCP-Snooping ARP** – information collected from snooping DHCP packets when DHCP snooping is enabled on VLANs.

The status of an ARP entry is either pending or valid:

- **Valid** – the mapping is valid, and the port is resolved. This is always the case for static ARP entries.
- **Pending** – for normal dynamic and inspection ARP entries before they are resolved, and the port mapped. Their status changes to valid when they are resolved, and the port mapped.

Refer to also [“System reboot and the binding database”](#) on page 1933.

Configuration notes and feature limitations for DAI

The following limits and restrictions apply when configuring DAI:

- To run Dynamic ARP Inspection, you must first enable support for ACL filtering based on VLAN membership or VE port membership. To do so, enter the following commands at the Global CONFIG Level of the CLI.

```
Brocade(config)#enable ACL-per-port-per-vlan
Brocade(config)#write memory
Brocade(config)#exit
Brocade#reload
```

NOTE

You must save the configuration and reload the software to place the change into effect.

- Brocade recommends that you do not enable DAI on a trunk port.
- The maximum number of DHCP and static DAI entries depends on the maximum number of ARP table entries allowed on the device. A FastIron Layer 2 switch can have up to 4096 ARP entries and a FastIron Layer 3 switch can have up to 64,000 ARP entries. In a FastIron Layer 3 switch, you can use the **system-max ip-arp** command to change the maximum number of ARP entries for the device.

However, only up to 1024 DHCP entries can be saved to flash.

- ACLs are supported on member ports of a VLAN on which DHCP snooping and Dynamic ARP Inspection (DAI) are enabled.
- On FastIron X Series devices, DAI is supported together with multi-device port authentication and dynamic ACLs. For details, refer to [“Support for dynamic ARP inspection with dynamic ACLs”](#) on page 1852.
- DAI is supported on a VLAN without a VE, or on a VE with or without an assigned IP address.

Dynamic ARP inspection configuration

Configuring DAI consists of the following steps.

1. Configure inspection ARP entries for hosts on untrusted ports. Refer to [“Configuring an inspection ARP entry”](#) on page 1930.
2. Enable DAI on a VLAN to inspect ARP packets. Refer to [“Enabling DAI on a VLAN”](#) on page 1930.
3. Configure the trust settings of the VLAN members. ARP packets received on *trusted* ports bypass the DAI validation process. ARP packets received on *untrusted* ports go through the DAI validation process. Refer to [“Enabling trust on a port”](#) on page 1931.
4. Enable DHCP snooping to populate the DHCP snooping IP-to-MAC binding database.

The following shows the default settings of DAI.

Feature	Default
Dynamic ARP Inspection	Disabled
Trust setting for ports	Untrusted

Configuring an inspection ARP entry

Static ARP and static inspection ARP entries need to be configured for hosts on untrusted ports. Otherwise, when DAI checks ARP packets from these hosts against entries in the ARP table, it will not find any entries for them, and the Brocade device will not allow and learn ARP from an untrusted host.

When the inspection ARP entry is resolved with the correct IP/MAC mapping, its status changes from pending to valid.

To configure an inspection ARP entry, enter a command such as the following.

```
Brocade(config)#arp 20.20.20.12 0001.0002.0003 inspection
```

This command defines an inspection ARP entry, mapping a device IP address 20.20.20.12 with its MAC address 0001.0002.0003. The ARP entry will be in **Pend** (pending) status until traffic with the matching IP-to-MAC is received on a port.

Syntax: [no] arp <ip-addr> <mac-addr> inspection

The <ip-addr> <mac-addr> parameter specifies a device IP address and MAC address pairing.

Enabling DAI on a VLAN

DAI is disabled by default. To enable DAI on an existing VLAN, enter the following command.

```
Brocade(config)#ip arp inspection vlan 2
```

The command enables DAI on VLAN 2. ARP packets from untrusted ports in VLAN 2 will undergo DAI inspection.

Syntax: [no] ip arp inspection vlan <vlan-number>

The <vlan-number> variable specifies the ID of a configured VLAN.

Enabling trust on a port

The default trust setting for a port is untrusted. For ports that are connected to host ports, leave their trust settings as untrusted.

To enable trust on a port, enter commands such as the following .

```
Brocade(config)#interface ethernet 1/4
Brocade(config-if-e10000-1/4)#arp inspection trust
```

The commands change the CLI to the interface configuration level of port 1/4 and set the trust setting of port 1/4 to trusted.

Syntax: [no] arp inspection trust

Displaying ARP inspection status and ports

To display the ARP inspection status for a VLAN and the trusted or untrusted port, enter the following command.

```
Brocade#show ip arp inspection vlan 2
IP ARP inspection VLAN 2: Disabled
  Trusted Ports :   ethe 1/4
  Untrusted Ports : ethe 2/1 to 2/3 ethe 4/1 to 4/24 ethe 6/1 to 6/4 ethe 8/1 to
                    8/4
```

Syntax: show ip arp inspection [vlan <vlan_id>]

The <vlan_id> variable specifies the ID of a configured VLAN.

Displaying the ARP table

To display the ARP table, enter the **show arp** command .

```
Brocade#show arp
Total number of ARP entries: 2, maximum capacity: 6000
No   IP Address      MAC Address      Type      Age      Port      Status
1    10.43.1.1         0004.80a0.4000   Dynamic   0        mgmt1     Valid
2    10.43.1.78        00e0.8160.6ab1   Dynamic   2        mgmt1     Valid
```

The command displays all ARP entries in the system. For field definitions, refer to [Table 184](#) on page 1071.

Syntax: show arp

DHCP snooping

Dynamic Host Configuration Protocol (DHCP) snooping enables the Brocade device to filter untrusted DHCP packets in a subnet. DHCP snooping can ward off MiM attacks, such as a malicious user posing as a DHCP server sending false DHCP server reply packets with the intention of misdirecting other users. DHCP snooping can also stop unauthorized DHCP servers and prevent errors due to user mis-configuration of DHCP servers.

Often DHCP snooping is used together with Dynamic ARP Inspection and IP Source Guard.

How DHCP snooping works

When enabled on a VLAN, DHCP snooping stands between untrusted ports (those connected to host ports) and trusted ports (those connected to DHCP servers). A VLAN with DHCP snooping enabled forwards DHCP request packets from clients and discards DHCP server reply packets on untrusted ports, and it forwards DHCP server reply packets on trusted ports to DHCP clients, as shown in the following figures

FIGURE 211 DHCP snooping at work - on an untrusted port

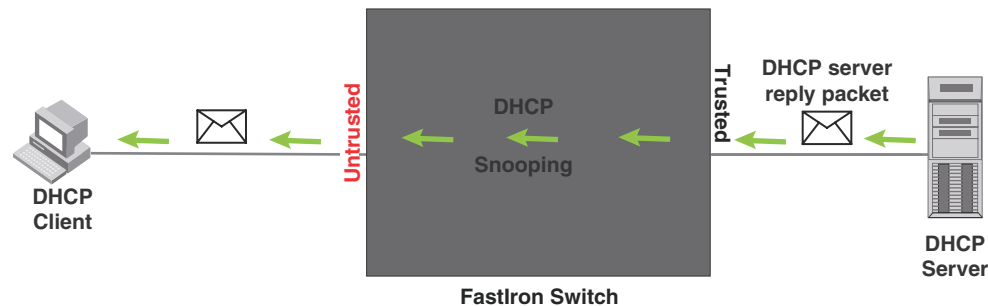

FIGURE 212 DHCP snooping at work - on a trusted port

DHCP binding database

When it forwards DHCP server reply packets on trusted ports, the Brocade device saves the client IP-to-MAC address binding information in the DHCP binding database. This is how the DHCP snooping binding table is populated. The information saved includes MAC address, IP address, lease time, VLAN number, and port number.

In the Brocade device, the DHCP binding database is integrated with the enhanced ARP table, which is used by Dynamic ARP Inspection. For more information, refer to [“ARP entries”](#) on page 1928.

The lease time will be refreshed when the client renews its IP address with the DHCP server; otherwise the Brocade device removes the entry when the lease time expires.

About client IP-to-MAC address mappings

Client IP addresses need not be on directly-connected networks, as long as the client MAC address is learned on the client port and the client port is in the same VLAN as the DHCP server port. In this case, the system will learn the client IP-to-MAC port mapping. Therefore, a VLAN with DHCP snooping enabled does not require a VE interface.

In earlier releases, in the Layer 3 software image, DHCP snooping does not learn the secure IP-to-MAC address mapping for a client, if the client port is not a virtual ethernet (VE) interface with an IP subnet address. In other words, the client IP address had to match one of the subnets of the client port in order for DHCP to learn the address mapping.

System reboot and the binding database

To allow DAI and DHCP snooping to work smoothly across a system reboot, the binding database is saved to a file in the system flash memory after an update to the binding database, with a 30 second delay. The flash file is written and read only if DHCP snooping is enabled.

Configuration notes and feature limitations for DHCP snooping

The following limits and restrictions apply to DHCP snooping:

- To run DHCP snooping, you must first enable support for ACL filtering based on VLAN membership or VE port membership. To do so, enter the following commands at the Global CONFIG Level of the CLI.

```
Brocade(config)#enable ACL-per-port-per-vlan
Brocade(config)#write memory
Brocade(config)#exit
Brocade#reload
```

NOTE

You must save the configuration and reload the software to place the change into effect.

- DHCP snooping is supported on trunk ports (tagged and untagged) for trusted ports.
- DHCP snooping is not supported on trunk ports for untrusted ports.
- DHCP snooping is not supported together with DHCP Auto-configuration.
- A switch can have up to 256 ARP entries, therefore, DHCP entries are limited to 256. A router, however, can have 64,000 ARP entries, so a router can have up to 64,000 DHCP entries, of which only 1024 entries can be saved to flash on reboot.
- ACLs are supported on member ports of a VLAN on which DHCP snooping and Dynamic ARP Inspection (DAI) are enabled.
- See also [“About client IP-to-MAC address mappings”](#) on page 1933.
- On FastIron X Series devices, DHCP snooping is supported together with multi-device port authentication and dynamic ACLs. For details, refer to [“Support for DHCP snooping with dynamic ACLs”](#) on page 1852.
- DHCP snooping supports DHCP relay agent information (DHCP Option 82). For details, refer to [“DHCP relay agent information”](#) on page 1936.

Configuring DHCP snooping

Configuring DHCP snooping consists of the following steps.

1. Enable DHCP snooping on a VLAN. Refer to [“Enabling DHCP snooping on a VLAN”](#) on page 1934.
2. For ports that are connected to a DHCP server, change their trust setting to trusted. Refer to [“Enabling trust on a port”](#) on page 1934.

The following shows the default settings of DHCP snooping.

Feature	Default
DHCP snooping	Disabled
Trust setting for ports	Untrusted

Enabling DHCP snooping on a VLAN

When DHCP snooping is enabled on a VLAN, DHCP packets are inspected.

DHCP snooping is disabled by default. This feature must be enabled on the client and the DHCP server VLANs. To enable DHCP snooping, enter the following global command for these VLANs.

```
Brocade(config)#ip dhcp snooping vlan 2
```

The command enables DHCP snooping on VLAN 2.

Syntax: [no] ip dhcp snooping vlan <vlan-number>

The <vlan-number> variable specifies the ID of a configured client or DHCP server VLAN.

Enabling trust on a port

The default trust setting for a port is untrusted. To enable trust on a port connected to a DHCP server, enter commands such as the following.

```
Brocade(config)#interface ethernet 1/1
Brocade(config-if-e10000-1/1)#dhcp snooping trust
```

Port 1/1 is connected to a DHCP server. The commands change the CLI to the interface configuration level of port 1/1 and set the trust setting of port 1/1 to trusted.

Syntax: [no] dhcp snooping trust

Disabling the learning of DHCP clients on a port

You can disable DHCP client learning on an individual port. To do so, enter commands such as the following.

```
Brocade(config)#interface ethernet 1/1
Brocade(config-if-e10000-1/1)#dhcp snooping client-learning disable
```

Syntax: [no] dhcp snooping client-learning disable

Use the **no** form of the command to re-enable DHCP client learning on a port once it has been disabled.

Clearing the DHCP binding database

You can clear the DHCP binding database using the CLI command **clear DHCP**. You can remove all entries in the database, or remove entries for a specific IP address only.

To remove all entries from the DHCP binding database, enter the **clear dhcp** command.

```
Brocade#clear dhcp
```

To clear entries for a specific IP address, enter a command such as the following.

```
Brocade#clear dhcp 10.10.102.4
```

Syntax: **clear dhcp** [*<ip-addr>*]

Displaying DHCP snooping status and ports

To display the DHCP snooping status for a VLAN and the trusted/untrusted port, use the **show ip dhcp snooping vlan** command.

```
Brocade#show ip dhcp snooping vlan 2
IP DHCP snooping VLAN 2: Enabled
```

Syntax: **show ip dhcp snooping** [vlan *<vlan-id>*]

Displaying the DHCP snooping binding database

To display the DHCP snooping binding database, use the **show ip dhcp snooping info** command.

```
Brocade#show ip dhcp snooping info
Dhcp snooping Info
Total learnt entries 1
SAVED DHCP ENTRIES IN FLASH
      IP Address      Mac Address      Port  vlan  lease
0      10.10.10.20      0001.0002.0003  6/13  1112  361
```

Syntax: **show ip dhcp snooping info**

Displaying DHCP binding entry and status

To display the DHCP binding entry and its current status, use the **show arp** command.

```
Brocade#show arp
Total number of ARP entries: 2, maximum capacity: 6000
No.   IP Address      MAC Address      Type    Age    Port    Status
1     10.43.1.1        00e0.0001.c320   Dynamic  0      mgmt1   Valid
2     10.43.1.199      00e0.0002.b263   Dynamic  7      mgmt1   Valid
```

Syntax: **show arp**

For field definitions, refer to [Table 184](#) on page 1071.

DHCP snooping configuration example

The following example configures VLAN 2 and VLAN 20, and changes the CLI to the global configuration level to enable DHCP snooping on the two VLANs. The commands are as follows.

```
Brocade(config)#vlan 2
Brocade(config-vlan-2)#untagged ethe 1/3 to 1/4
Brocade(config-vlan-2)#router-interface ve 2
Brocade(config-vlan-2)#exit
Brocade(config)#ip dhcp snooping vlan 2

Brocade(config)#vlan 20
Brocade(config-vlan-20)#untagged ethe 1/1 to 1/2
Brocade(config-vlan-20)#router-interface ve 20
Brocade(config-vlan-20)#exit
Brocade(config)#ip dhcp snooping vlan 20
```

On VLAN 2, client ports 1/3 and 1/4 are untrusted by default all client ports are untrusted. Hence, only DHCP client request packets received on ports 1/3 and 1/4 are forwarded.

On VLAN 20, ports 1/1 and 1/2 are connected to a DHCP server. DHCP server ports are set to trusted .

```
Brocade(config)#interface ethernet 1/1
Brocade(config-if-e10000-1/1)#dhcp snooping trust
Brocade(config-if-e10000-1/1)#exit
Brocade(config)#interface ethernet 1/2
Brocade(config-if-e10000-1/2)#dhcp snooping trust
Brocade(config-if-e10000-1/2)#exit
```

Hence, DHCP server reply packets received on ports 1/1 and 1/2 are forwarded, and client IP/MAC binding information is collected.

The example also sets the DHCP server address for the local relay agent.

```
Brocade(config)#interface ve 2
Brocade(config-vif-2)#ip address 20.20.20.1/24
Brocade(config-vif-2)#ip helper-address 1 30.30.30.4
Brocade(config-vif-2)#interface ve 20
Brocade(config-vif-20)#ip address 30.30.30.1/24
```

DHCP relay agent information

DHCP relay agent information, also known as DHCP option 82, enables a DHCP relay agent to insert information about a clients' identity into a DHCP client request being sent to a DHCP server.

When DHCP snooping is enabled on the FastIron switch, DHCP option 82 is automatically enabled. DHCP packets are processed as follows:

- Before relaying a DHCP discovery packet or DHCP request packet from a client to a DHCP server, the FastIron switch will add agent information to the packet.
- Before relaying a DHCP reply packet from a DHCP server to a client, the FastIron switch will remove relay agent information from the packet.

As illustrated in [Figure 213](#), the DHCP relay agent (the FastIron switch), inserts DHCP option 82 attributes when relaying a DHCP request packet to a DHCP server.

FIGURE 213 DHCP Option 82 attributes added to the DHCP packet

As illustrated in [Figure 214](#), the FastIron switch deletes DHCP option 82 attributes before forwarding a server reply packet back to a DHCP client.

FIGURE 214 DHCP Option 82 attributes removed from the DHCP packet

The DHCP option 82 insertion/deletion feature is available only when DHCP snooping is enabled for the client/server ports.

Configuration notes for DHCP option 82

- DHCP snooping and DHCP option 82 are supported on a per-VLAN basis.
- DHCP option 82 follows the same configuration rules and limitations as for DHCP snooping. For more information, refer to [“Configuration notes and feature limitations for DHCP snooping”](#) on page 1933.

DHCP Option 82 sub-options

The Brocade implementation of DHCP Option 82 supports the following sub-options:

- Sub-Option 1 – Circuit ID
- Sub-Option 2 – Remote ID
- Sub-Option 6 – Subscriber ID

These sub-options are described in the following sections.

Sub-option 1 – circuit id

The Circuit ID (CID) identifies the circuit or port from which a DHCP client request was sent. The FastIron switch uses this information to relay DHCP responses back to the proper circuit, for example, the port number on which the DHCP client request packet was received.

Brocade FastIron devices support the **General CID packet format**. This simple format encodes the CID type, actual information length, VLAN ID, slot number, and port number. This format is compatible with the format used by other vendors' devices. [Figure 215](#) illustrates the general CID packet format.

FIGURE 215 General CID packet format***Sub-option 2 – Remote ID***

The Remote ID (RID) identifies the remote host end of the circuit (the relay agent). Brocade devices use the MAC address to identify itself as the relay agent. [Figure 216](#) illustrates the RID packet format.

FIGURE 216 RID packet format***Sub-option 6 - subscriber id***

The Subscriber ID (SID) is a unique identification number that enables an Internet Service Provider to:

- Identify a subscriber
- Assign specific attributes to that subscriber (for example, host IP address, subnet mask, and domain name server (DNS))
- Trigger accounting

[Figure 217](#) illustrates the SID packet format.

FIGURE 217 SID packet format

The second byte (*N* in [Figure 217](#)) is the length of the ASCII string that follows. The FastIron switch supports up to 50 ASCII characters.

DHCP option 82 configuration

When DHCP snooping is enabled on a VLAN, DHCP option 82 also is enabled by default. You do not need to perform any extra configuration steps to enable this feature. To enable DHCP snooping, refer to [“Enabling DHCP snooping on a VLAN”](#) on page 1934.

When processing DHCP packets, the FastIron switch applies the following default behavior when DHCP option 82 is enabled:

- Subjects all ports in the VLAN to DHCP option 82 processing
- Uses the general CID packet format
- Uses the standard RID packet format
- Replaces relay agent information received in DHCP packets with its own information
- Does not enable SID processing

When DHCP option 82 is enabled, you can optionally:

- Disable DHCP Option 82 processing on individual ports in the VLAN
- Configure the device to drop or keep the relay agent information in a DHCP packet instead of replacing it with its own information
- Enable SID processing

Disabling and re-enabling DHCP option 82 processing on an individual interface

By default, when DHCP option 82 is enabled on a VLAN, DHCP packets received on all member ports of the VLAN are subject to DHCP option 82 processing. You can optionally disable and later re-enable DHCP option 82 processing on one or more member ports of the VLAN. To do so, use the commands in this section.

To disable a particular port in a VLAN from adding relay agent information to DHCP packets, enter commands such as the following.

```
Brocade(config)#ip dhcp snooping vlan 1
Brocade(config)#interface ethernet 1/4
Brocade(config-if-e1000-1/4)#no dhcp snooping relay information
```

The first CLI command enables DHCP snooping and DHCP option 82 on VLAN 1. The second command changes the CLI configuration level to the Interface configuration level for port e 1/4. The last command disables DHCP option 82 on interface e 1/4, which is a member of VLAN 1.

To re-enable DHCP option 82 on an interface after it has been disabled, enter the following command at the Interface level of the CLI.

```
Brocade(config-if-e1000-1/4)#dhcp snooping relay information
```

Syntax: [no] dhcp snooping relay information

Use the show ip dhcp snooping vlan command to view the ports on which DHCP option 82 processing is disabled. For more information, refer to [“Viewing the ports on which DHCP option 82 is disabled”](#) on page 1941.

Changing the forwarding policy

When the Brocade device receives a DHCP message that contains relay agent information, by default, the device replaces the information with its own relay agent information. If desired, you can configure the device to keep the information instead of replacing it, or to drop (discard) messages that contain relay agent information. To do so, use the CLI commands in this section.

For example, to configure the device to *keep* the relay agent information contained in a DHCP message, enter the **ip dhcp relay information policy keep** command.

```
Brocade(config)#ip dhcp relay information policy keep
```

To configure the device to *drop* DHCP messages that contain relay agent information, enter the **ip dhcp relay information policy drop** command.

```
Brocade(config)#ip dhcp relay information policy drop
```

Syntax: **ip dhcp relay information policy** *<policy-type>*

<policy-type> can be one of the following:

- **drop** – Configures the device to discard messages containing relay agent information
- **keep** – Configures the device to keep the existing relay agent information
- **replace** – Configures the device to overwrite the relay agent information with the information in the Brocade configuration. This is the default behavior.

Use the **show ip dhcp relay information** command to view the forwarding policy configured on the switch. Refer to [“Viewing the circuit id, remote id, and forwarding policy”](#) on page 1941.

Enabling and disabling subscriber ID processing

You can configure a unique subscriber ID (SID) per port. Unlike the CID and RID sub-options, the SID sub-option is not automatically enabled when DHCP option 82 is enabled. To enable SID processing, enter commands such as the following.

```
Brocade(config)#ip dhcp snooping vlan 1
Brocade(config)#interface ethernet 1/4
Brocade(config-if-e1000-1/4)#dhcp snooping relay information subscriber-id Brcd01
```

The first CLI command enables DHCP snooping and DHCP option 82 on VLAN 1. The second command changes the CLI configuration level to the Interface configuration level for port e 1/4. The last command enables interface e 1/4 to insert the SID information in DHCP packets. In this case, the SID is **Brcd01**. All other ports in VLAN 1 on which SID is not enabled will send the standard relay agent information (CID and RID information) only.

Syntax: **[no] dhcp snooping relay information option subscriber-id** *<ASCII string>*

Enter up to 50 alphanumeric characters for *<ASCII string>*.

Use the **no** form of the command to disable SID processing once it is enabled.

Use the **show interfaces ethernet** command to view the subscriber ID configured on a port. Refer to [“Viewing the status of DHCP option 82 and the subscriber id”](#) on page 1942.

Viewing information about DHCP option 82 processing

Use the commands in this section to view information about DHCP option 82 processing.

Viewing the circuit id, remote id, and forwarding policy

Use the **show ip dhcp relay information** command to obtain information about the circuit ID, remote ID, and forwarding policy for DHCP option 82. The following shows an example output.

```
Brocade#show ip dhcp relay information
Relay Information: Format: Circuit-ID : vlan-mod-port
                    Remote-ID : mac
                    Policy : keep
```

Syntax: show ip dhcp relay information

TABLE 318 Output for the ip dhcp relay information command

Field	Description
Circuit-ID	The agent circuit ID format: <ul style="list-style-type: none"> vlan-mod-port – The default circuit ID format.
Remote-ID	The remote ID format. This field displays mac , which is the default remote ID format.
Policy	How the Brocade switch processes relay agent information it receives in DHCP messages: <ul style="list-style-type: none"> drop – drops the relay agent information keep – keeps the relay agent information replace – replaces the relay agent information with its own

Viewing the ports on which DHCP option 82 is disabled

Use the following command to refer which port in a DHCP snooping VLAN has DHCP Option 82 disabled.

```
Brocade#show ip dhcp snooping vlan 1
IP DHCP snooping VLAN 1: Enabled
  Trusted Ports :   ethe 3
  Untrusted Ports : ethe 1 to 2 ethe 4 to 24
  Relay Info. disabled Ports: ethe 10
```

Syntax: show ip dhcp snooping vlan <vlan-id>

TABLE 319 Output for the show ip dhcp snooping vlan command

Field	Description
IP DHCP snooping VLAN <vlan-id>	The DHCP snooping and DHCP option 82 status for a VLAN: <ul style="list-style-type: none"> Enabled Disabled
Trusted Ports	A list of trusted ports in the VLAN.
Untrusted Ports	A list of untrusted ports in the VLAN.
Relay Info. disabled Ports	Ports on which DHCP option 82 was disabled.

Viewing the status of DHCP option 82 and the subscriber id

Use the **show interfaces ethernet** command to obtain information about the status of DHCP option 82 and the configured subscriber ID, if applicable. In the example below, the text in **bold** type displays the information specific to DHCP option 82.

```
Brocade#show interfaces ethernet 3
GigabitEthernet3 is up, line protocol is up
  Hardware is GigabitEthernet, address is 00e0.5200.0002 (bia 00e0.5200.0002)
  Configured speed auto, actual 1Gbit, configured duplex fdx, actual fdx
  Configured mdi mode AUTO, actual MDI
  Member of L2 VLAN ID 1, port is untagged, port state is FORWARDING
  BPDU guard is Disabled, ROOT protect is Disabled
  Link Error Dampening is Disabled
  STP configured to ON, priority is level0
  Flow Control is config enabled, oper enabled, negotiation disabled
  mirror disabled, monitor disabled
  Not member of any active trunks
  Not member of any configured trunks
  No port name
  IPG MII 96 bits-time, IPG GMII 96 bits-time
  IP MTU 1500 bytes
  300 second input rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
  300 second output rate: 264 bits/sec, 0 packets/sec, 0.00% utilization
  0 packets input, 0 bytes, 0 no buffer
  Received 0 broadcasts, 0 multicasts, 0 unicasts
  0 input errors, 0 CRC, 0 frame, 0 ignored
  0 runs, 0 giants
  0 packets output, 0 bytes, 0 underruns
  Transmitted 0 broadcasts, 0 multicasts, 0 unicasts
  0 output errors, 0 collisions
    Relay Agent Information option: Enabled, Subscriber-ID: Brocade001
```

The above output shows that DHCP option 82 is **Enabled** on the device and the configured subscriber ID is **Brocade001**.

Syntax: **show interfaces ethernet** <port>

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

IP source guard

You can use IP Source Guard together with Dynamic ARP Inspection on untrusted ports. Refer to [“DHCP snooping”](#) on page 1931 and [“Dynamic ARP inspection”](#) on page 1927.

The Brocade implementation of the IP Source Guard feature supports configuration on a port, on specific VLAN memberships on a port (Layer 2 devices only), and on specific ports on a virtual interface (VE) (Layer 3 devices only).

When IP Source Guard is first enabled, only DHCP packets are allowed and all other IP traffic is blocked. When the system learns a valid IP address, IP Source Guard then allows IP traffic. Only the traffic with valid source IP addresses are permitted. The system learns of a valid IP address from DHCP Snooping. When it learns a valid IP address, the system permits the learned source IP address.

When a new IP source entry binding on the port is created or deleted, the ACL will be recalculated and reapplied in hardware to reflect the change in IP source binding. By default, if IP Source Guard is enabled without any IP source binding on the port, an ACL that denies all IP traffic is loaded on the port.

Configuration notes and feature limitations for IP source guard

- To run IP Source Guard, you must first enable support for ACL filtering based on VLAN membership or VE port membership. To do so, enter the following commands at the Global CONFIG Level of the CLI.

```
Brocade(config)#enable ACL-per-port-per-vlan
Brocade(config)#write memory
Brocade(config)#exit
Brocade#reload
```

NOTE

You must save the configuration and reload the software to place the change into effect.

- Brocade FWS and FCX devices do not support IP Source Guard and dynamic ACLs on the same port.
- Brocade devices support IP Source Guard together with IPv4 ACLs (similar to ACLs for Dot1x), as long as both features are configured at the port-level or per-port-per-VLAN level. Brocade devices do not support IP Source Guard and IPv4 ACLs on the same port if one is configured at the port-level and the other is configured at the per-port-per-VLAN level.
- IP source guard and IPv6 ACLs are supported together on the same device, as long as they are not configured on the same port or virtual Interface.
- The following limitations apply when configuring IP Source Guard on Layer 3 devices:
 - You cannot enable IP Source Guard on a tagged port on a Layer 3 device. To enable IP Source Guard on a tagged port, enable it on a per-VE basis.
 - You cannot enable IP Source Guard on an untagged port with VE on a Layer 3 device. To enable IP Source Guard in this configuration, enable it on a per-VE basis.
 - There are no restrictions for Layer 2, either on the port or per-VLAN.
- You cannot enable IP Source Guard on a port that has any of the following features enabled:
 - MAC address filter
 - Rate limiting
 - Trunk port
 - 802.1x with ACLs
 - Multi-device port authentication with ACLs
- A port on which IP Source Guard is enabled limits the support of IP addresses, VLANs, and ACL rules per port. An IP Source Guard port supports a maximum of:

- 64 IP addresses
- 64 VLANs
- 64 rules per ACL
- The number of configured ACL rules affect the rate at which hardware resources are used when IP Source Guard is enabled. Use the **show access-list hw-usage on** command to enable hardware usage for an ACL, followed by a **show access-list <access-list-id>** command to determine the hardware usage for an ACL.

Example

```
Brocade#show access-list hw-usage on
Brocade#show access-list 100
Extended IP access list 100 (hw usage : 2)
deny ip any any (hw usage : 1)
```

To provide more hardware resource for IP Source Guard addresses, modify the ACL rules so that it uses less hardware resource.

- If you enable IP Source Guard in a network topology that has DHCP clients, you must also enable DHCP snooping. Otherwise, all IP traffic including DHCP packets will be blocked.
- When you enable IP Source Guard in a network topology that does not have DHCP clients, you must create an IP source binding for each client that will be allowed access to the network. Otherwise, data packets will be blocked. Refer to [“Defining static IP source bindings”](#) on page 1944.
- Source Guard Protection enables concurrent support with multi-device port authentication. For details, Refer to [“Enabling source guard protection”](#) on page 1864.
- IP Source Guard is supported on a VE with or without an assigned IP address.

Enabling IP source guard on a port

You can enable IP Source Guard on DHCP snooping untrusted ports. Refer to [“DHCP snooping”](#) on page 1931 for how to configure DHCP and DHCP untrusted ports.

By default, IP Source Guard is disabled. To enable IP Source Guard on a DHCP untrusted port, enter the following commands.

```
Brocade(config)#interface ethernet 1/4
Brocade(config-if-e10000-1/4)#source-guard enable
```

The commands change the CLI to the interface configuration level for port 1/4 and enable IP Source Guard on the port.

Syntax: [no] source-guard enable

Defining static IP source bindings

You can manually enter valid IP addresses in the binding database. To do so, enter a command such as the following.

```
Brocade(config)#ip source binding 10.10.10.1 e 2/4 vlan 4
```

Syntax: [no] ip source binding <ip-addr> ethernet [<slotnum> / <portnum>] [vlan <vlannum>]

For <ip-addr>, enter a valid IP address.

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter is a valid port number.

The `[vlan <vlannum>]` parameter is optional. If you enter a VLAN number, the binding applies to that VLAN only. If you do not enter a VLAN number, the static binding applies to all VLANs associated with the port. Note that since static IP source bindings consume system resources, you should avoid unnecessary bindings.

Enabling IP source guard per-port-per-VLAN

To enable IP Source Guard per-port-per VLAN, enter commands such as the following.

```
Brocade(config)#vlan 12 name vlan12
Brocade(config-vlan-12)#untag ethernet 5 to 8
Brocade(config-vlan-12)#tag ethernet 23 to 24
Brocade(config-vlan-12)#exit
Brocade(config)#int e 23
Brocade(config-if-e1000-23)#per-vlan vlan12
Brocade(config-if-e1000-23-vlan-12)#source-guard enable
```

The commands in this example configure port-based VLAN 12, and add ports e 5 – 8 as untagged ports and ports e 23 – 24 as tagged ports to the VLAN. The last two commands enable IP Source Guard on port e 23, a member of VLAN 12.

Syntax: `[no] source-guard enable`

Enabling IP source guard on a VE

To enable IP Source Guard on a virtual interface, enter commands such as the following.

```
Brocade(config)#vlan 2
Brocade(config-vlan-2)#tag e1
Added tagged port(s) ethe 1 to port-vlan 2
Brocade(config-vlan-2)#router-int ve 2
Brocade(config-vlan-2)#int ve 2
Brocade(config-vif-2)#source-guard enable e 1
```

Syntax: `[no] source-guard enable`

Displaying learned IP addresses

To display the learned IP addresses for IP Source Guard ports, use the CLI commands **show ip source-guard ethernet**.

IP source guard

Rate Limiting and Rate Shaping on FastIron X Series and FCX and ICX Series Switches

[Table 320](#) lists the individual Brocade FastIron switches and the rate limiting and rate shaping features they support. These features are supported in the Layer 2, base Layer 3, edge Layer 3, and full Layer 3 software images, except where explicitly noted.

TABLE 320 Supported rate limiting and rate shaping features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
Inbound rate limiting (Port-based rate limiting on inbound ports)	Yes	Yes	Yes	Yes	Yes
Outbound rate shaping	Yes	For details about inbound rate and outbound limiting on FastIron WS Series devices, see Chapter 50, "Rate Limiting on FastIron WS Series Switches,"	Yes	Yes	Yes
ACL-based rate limiting	Yes	Yes	Yes	Yes	Yes
	For details about ACL-based rate limiting, see Chapter 42, "Traffic Policies" .				

This chapter describes how to configure rate limiting and rate shaping on Brocade FastIron X Series, Brocade FCX Series, Brocade ICX 6610, Brocade ICX 6430, and Brocade ICX 6450 devices.

Rate limiting applies to inbound ports and rate shaping applies to outbound ports.

Rate limiting overview

Port-based fixed rate limiting is supported on inbound ports. This feature allows you to specify the maximum number of *bytes* a given port can receive. The port drops bytes that exceed the limit you specify. You can configure a Fixed rate limiting policy on a port inbound direction only. Fixed rate limiting applies to all traffic on the rate limited port.

Fixed rate limiting is at line rate and occurs in hardware. Refer to ["Rate limiting in hardware"](#) on page 1948.

When you specify the maximum number of bytes, you specify it in kilobits per second (kbps). The Fixed rate limiting policy applies to one-second intervals and allows the port to receive the number of bytes you specify in the policy, but drops additional bytes. Unused bandwidth is not carried over from one interval to the next.

NOTE

Brocade recommends that you do not use Fixed rate limiting on ports that receive route control traffic or Spanning Tree Protocol (STP) control traffic. If the port drops control packets due to the Fixed rate limiting policy, routing or STP can be disrupted.

Rate limiting in hardware

Each Brocade device supports line-rate rate limiting in hardware. The device creates entries in Content Addressable Memory (CAM) for the rate limiting policies. The CAM entries enable the device to perform the rate limiting in hardware instead of sending the traffic to the CPU. The device sends the first packet in a given traffic flow to the CPU, which creates a CAM entry for the traffic flow. A CAM entry consists of the source and destination addresses of the traffic. The device uses the CAM entry for rate limiting all the traffic within the same flow. A rate limiting CAM entry remains in the CAM for two minutes before aging out.

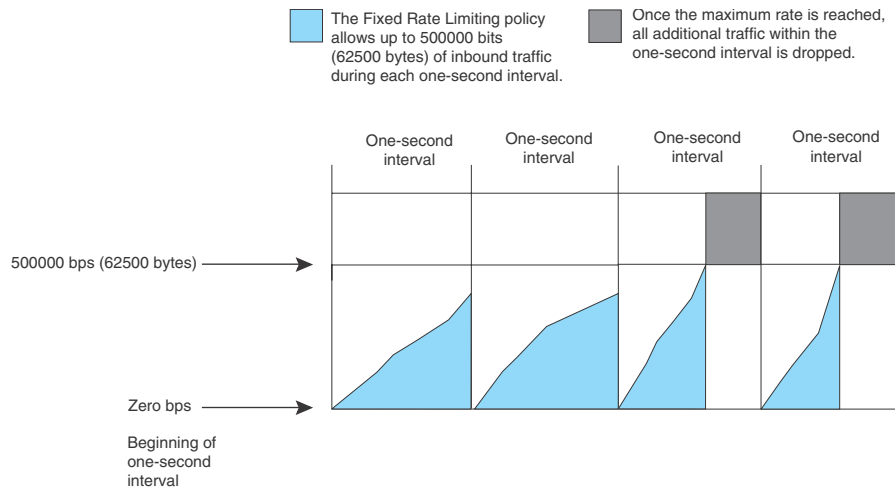

How Fixed rate limiting works

Fixed rate limiting counts the number of bytes that a port receives, in one second intervals. If the number exceeds the maximum number you specify when you configure the rate, the port drops all further inbound packets for the duration of the one-second interval.

Once the one-second interval is complete, the port clears the counter and re-enables traffic.

[Figure 218](#) shows an example of how Fixed rate limiting works. In this example, a Fixed rate limiting policy is applied to a port to limit the inbound traffic to 500000 bits (62500 bytes) a second. During the first two one-second intervals, the port receives less than 500000 bits in each interval. However, the port receives more than 500000 bits during the third and fourth one-second intervals, and consequently drops the excess traffic.

FIGURE 218 Fixed rate limiting

**NOTE**

The software counts the bytes by polling statistics counters for the port every 100 milliseconds, which provides 10 readings each second. Due to the polling interval, the Fixed Rate Limiting policy has an accuracy of within 10% of the port's line rate. It is therefore possible for the policy to sometimes allow more traffic than the limit you specify, but the extra traffic is never more than 10% of the port's line rate.

Configuration notes for rate limiting

- Rate limiting is available only on inbound ports.
- Port based Rate limiting is not supported on the SX-FI62XG and SX-FI42XG modules of the FastIron X Series devices.
- FastIron X Series devices do not support fixed rate limiting on tagged ports in the base Layer 3 and full Layer 3 images.
- The rate limit on IPv6 hardware takes several seconds to take effect at higher configured rate limit values. For example, if the configured rate limit is 750 Mbps, line-rate limiting could take up to 43 seconds to take effect.

Configuring a port-based rate limiting policy

To configure rate limiting on a port, enter commands such as the following.

```
Brocade(config)#interface ethernet 24
Brocade(config-if-e1000-24)#rate input fixed 500
```

These commands configure a fixed rate limiting policy that allows port 24 to receive a maximum of 500 kbits per second. If the port receives additional bytes during a given one-second interval, the port drops all inbound packets on the port until the next one-second interval starts.

Syntax: `[no] rate-limit input fixed <average-rate>`

For FastIron devices, the `<average-rate>` parameter specifies the maximum number of *kilobits* per second (kbps) the port can receive. The minimum rate that can be configured is 64 kbps.

Configuring an ACL-based rate limiting policy

IP ACL-based rate limiting of inbound traffic provides the facility to limit the rate for IP traffic that matches the permit conditions in extended IP ACLs. This feature is available in the Layer 2 and Layer 3 code.

To configure ACL-based rate limiting on a Brocade device, you create individual **traffic policies**, then reference the traffic policies in one or more ACL entries (also called clauses or statements). The traffic policies become effective on ports to which the ACLs are bound.

For configuration procedures for ACL-based rate limiting, refer to [Chapter 42, “Traffic Policies”](#).

Displaying the fixed rate limiting configuration

To display the fixed rate limiting configuration on the device, enter the **show rate-limit input** command.

```
Brocade# show rate-limit input
Total rate-limited interface count: 5.
  Port      Configured Input Rate      Actual Input Rate
  1/1              65000              65000
  1/2             195000             195000
  1/6              1950              1950
  5/2            230432            230000
  5/6            234113            234000
```

Syntax: show rate-limit input

The command lists the ports on which fixed rate limiting is configured, and provides the information listed in [Table 321](#) for each of the ports.

TABLE 321 CLI display of Fixed rate limiting information

Field	Description
Total rate-limited interface count	The total number of ports that are configured for Fixed rate limiting.
Port	The port number.
Configured Input Rate	The maximum rate requested for inbound traffic. The rate is measured in kilobits per second (kbps).
Actual Input Rate	The actual maximum rate provided by the hardware. The rate is measured in bps.

Rate shaping overview

Outbound Rate Shaping is a port-level feature that is used to shape the rate and control the bandwidth of outbound traffic on a port. This feature smooths out excess and bursty traffic to the configured maximum limit before it is sent out on a port. Packets are stored in available buffers and then forwarded at a rate no greater than the configured limit. This process provides for better control over the inbound traffic of neighboring devices.

The device has one global rate shaper for a port and one rate shaper for each port priority queue. Rate shaping is done on a single-token basis, where each token is defined to be 1 byte.

Configuration notes for rate shaping

The following rules apply when configuring outbound rate shapers:

- Outbound rate shapers can be configured *only* on physical ports, not on virtual or loopback ports.
- For trunk ports, the rate shaper must be configured on individual ports of a trunk using the **config-trunk-ind** command (trunk configuration level); you cannot configure a rate shaper for a trunk.
- This feature is supported on FastIron X Series and Brocade FCX Series devices only.
- When outbound rate shaping is enabled on a port on an IPv4 device, the port QoS queuing method (**qos mechanism**) will be strict mode. This applies to IPv4 devices only. On IPv6 devices, the QoS mechanism is whatever method is configured on the port, even when outbound rate shaping is enabled.
- You can configure a rate shaper for a port and for the individual priority queues of that port. However, if a port rate shaper is configured, that value overrides the rate shaper value of a priority queue if the priority queue rate shaper is greater than the rate shaper for the port.

The configured rate shaper values are rounded up to the nearest multiples of minimum values supported on the platform. [Table 322](#) shows the minimum and maximum values for output rate shaping on various devices. Values are in Kbps.

TABLE 322 Output rate shaping on FastIron devices

Device	Module	Minimum	Maximum
ICX 6610	1 Gbps ports	3	999750
ICX 6610	10 Gbps ports	3388	9996513
FCX	1 Gbps ports	89	999666
FCX	10 Gbps ports	3388	9996513
FSX	SX-FI48GPP module	51	999485
FSX	SX-FI-24GPP module	51	999485
FSX	SX-FI424P module	651	999936

Configuring outbound rate shaping for a port

To configure the maximum rate at which outbound traffic is sent out on a port, enter commands such as the following.

```
Brocade(config)#interface e 1/2
Brocade(config-if-e1000-2)#rate-limit output shaping 1300
```

The above commands affect FastIron X Series and Brocade FCX Series systems differently:

- On FastIron X Series devices, the configured 1300 Kbps outbound rate shaping on port 2 is rounded up to the nearest multiple of 651 Kbps, which is 1302 Kbps. This value is the actual limit on the port for outbound traffic.
- On Brocade FCX Series devices, the configured outbound rate shaper of 651 Kbps on port 1/15 is rounded to 616 Kbps. The configured 1300 Kbps limit on port 15 is rounded to 1232 Kbps..

Syntax: [no] **rate-limit output shaping** <value>

Configuring outbound rate shaping for a specific priority

To configure the maximum rate at which outbound traffic is sent out on a port priority queue, enter commands such as the following.

```
Brocade(config)#interface e 1/2
Brocade(config-if-e1000-2)#rate-limit output shaping 500 priority 7
```

The above commands affect FastIron X Series and Brocade FCX Series systems differently:

- On FastIron X Series devices, the configured 500 Kbps limit for outbound traffic on Priority queue 7 on port 2 is rounded up to the nearest multiple of 651 Kbps, which is 651 Kbps.
- On Brocade FCX Series devices, the configured 500 Kbps limit for outbound traffic on priority queue 7 on port 2 is rounded to a value that is programmable by the hardware, which is 440 Kbps.

Syntax: [no] **rate-limit output shaping** <value> **priority** <priority-queue>

Specify 0-7 for <priority-queue>

Configuring outbound rate shaping for a trunk port

This feature is supported on individual ports of a static trunk group and on LACP trunk ports. However, it is not supported on LACP trunk ports for FCX devices.

To configure the maximum rate at which outbound traffic is sent out on a trunk port, enter the following on each trunk port where outbound traffic will be shaped.

```
Brocade(config)#trunk e 1/13 to 1/16
Brocade(config-trunk-13-16)#config-trunk-ind
Brocade(config-trunk-13-16)#rate-limit output shaping ethe 1/15 651
Brocade(config-trunk-13-16)#rate-limit output shaping ethe 1/14 1300
```

The above commands configure an outbound rate shaper on port 1/14 and port 1/15. The commands affect FastIron X Series devices and Brocade FCX Series devices differently:

- On FastIron X Series devices, the configured outbound rate shaper (651 Kbps) on port 1/15 is the maximum rate of outbound traffic that is sent out on that port, since 651 Kbps is a multiple of 651 Kbps. The configured 1300 Kbps limit on port 14 is rounded up to 1302 Kbps.
- On Brocade FCX Series devices, the configured outbound rate shaper (651 Kbps) on port 1/15 is the rounded to 616 Kbps. The configured 1300 Kbps limit on port 14 is rounded to 1232 Kbps.

Syntax: [no] **rate-limit output shaping ethernet** <port> <value>

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Displaying rate shaping configurations

To display the configured outbound rate shaper on a device, enter the **show rate-limit output-shaping** command.

```
Brocade#show rate-limit output-shaping
```

Outbound Rate Shaping Limits in Kbps:

Port	PortMax	Prio0	Prio1	Prio2	Prio3	Prio4	Prio5	Prio6	Prio7
1	-	-	-	-	-	-	-	-	651
2	1302	-	-	-	-	-	-	-	-
15	651	-	-	-	-	-	-	-	-

The display lists the ports on a device, the configured outbound rate shaper on a port and for a priority for a port.

Rate Limiting on FastIron WS Series Switches

[Table 323](#) lists the individual Brocade FastIron switches and the rate limiting features they support. These features are supported in the Layer 2, base Layer 3, edge Layer 3, and full Layer 3 software images, except where explicitly noted.

TABLE 323Supported rate limiting features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	FCX	ICX 6610	ICX 6430 ICX 6450
Inbound rate limiting (Port-based rate limiting on inbound ports)	Yes For details, see Chapter 49 on page 1947 .	Yes	Yes For details, see Chapter 49 on page 1947 .	Yes For details, see Chapter 49 on page 1947 .	Yes For details, see Chapter 49 on page 1947	Yes For details, see Chapter 49 on page 1947
Outbound rate limiting (Port-based and port- and priority-based rate limiting on outbound ports)	No	Yes	No	No	No	No
ACL-based rate limiting	Yes	Yes	Yes	Yes	No	No

For details about ACL-based rate limiting, see [Chapter 42, "Traffic Policies"](#).

This chapter describes how to configure fixed rate limiting on inbound and outbound ports on FWS devices using the CLI.

Rate limiting overview

Fixed rate limiting allows you to specify the maximum number of bytes a given port can send or receive. The port drops bytes that exceed the limit you specify. You can configure a Fixed rate limiting policy on a port inbound or outbound direction. Fixed rate limiting applies to all traffic on the rate limited port.

When you specify the maximum number of bytes, you specify it in kilobits per second (Kbps). The Fixed rate limiting policy applies to one-second intervals and allows the port to send or receive the number of bytes you specify in the policy, but drops additional bytes. Unused bandwidth is not carried over from one interval to the next.

NOTE

Brocade recommends that you do not use Fixed rate limiting on ports that send or receive route control traffic or Spanning Tree Protocol (STP) control traffic. If the port drops control packets due to the Fixed rate limiting policy, routing or STP can be disrupted.

Rate limiting in hardware

Each device supports line-rate rate limiting in hardware. The device creates entries in Content Addressable Memory (CAM) for the rate limiting policies. The CAM entries enable the device to perform the rate limiting in hardware instead of sending the traffic to the CPU. The device sends the first packet in a given traffic flow to the CPU, which creates a CAM entry for the traffic flow. A CAM entry consists of the source and destination addresses of the traffic. The device uses the CAM entry for rate limiting all the traffic within the same flow. A rate limiting CAM entry remains in the CAM for two minutes before aging out.

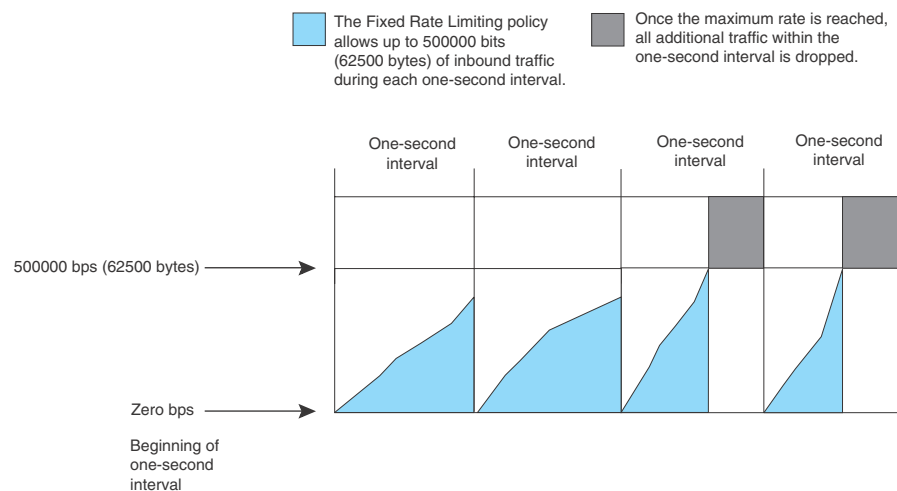

How fixed rate limiting works

Fixed rate limiting counts the number of bytes that a port either sends or receives, in one second intervals. The direction that the software monitors depends on the direction you specify when you configure the rate limit on the port. If the number of bytes exceeds the maximum number you specify when you configure the rate, the port drops all further packets for the rate-limited direction, for the duration of the one-second interval.

Once the one-second interval is complete, the port clears the counter and re-enables traffic.

Figure 219 shows an example of how Fixed rate limiting works. In this example, a Fixed rate limiting policy is applied to a port to limit the inbound traffic to 500000 bits (62500 bytes) a second. During the first two one-second intervals, the port receives less than 500000 bits in each interval. However, the port receives more than 500000 bits during the third and fourth one-second intervals, and consequently drops the excess traffic.

FIGURE 219 Fixed rate limiting

NOTE

The software counts the bytes by polling statistics counters for the port every 100 milliseconds, which provides 10 readings each second. Due to the polling interval, the Fixed Rate Limiting policy has an accuracy of within 10% of the port's line rate. It is therefore possible for the policy to sometimes allow more traffic than the limit you specify, but the extra traffic is never more than 10% of the port's line rate.

Fixed rate limiting on inbound port configuration

Inbound rate limiting allows you to specify the maximum number of Kbps a given port can receive.

Minimum and maximum inbound rate limits

[Table 324](#) lists the minimum and maximum inbound rate limits on GbE and 10-GbE ports

TABLE 324 Rates for inbound rate limiting

Port type	Minimum rate	Maximum rate
GbE	65 Kbps	1000000 Kbps
10-GbE	65 Kbps	10000000 Kbps

Configuration notes for fixed rate limiting

Inbound rate limiting is **supported** on:

- GbE ports
- 10-GbE ports
- Trunk ports

Inbound rate limiting is **not supported** on:

- Ports on which LACP is enabled
- Virtual interfaces
- Loopback interfaces

Fixed rate limiting is **supported** on:

- inbound ports only

Fixed rate limiting is **not supported** on:

- 10 Gbps Ethernet ports
- Tagged ports in the base Layer 3 and full Layer 3 images

Configuration syntax for fixed rate limiting

To configure inbound rate limiting on a port, enter commands such as the following.

```
Brocade(config)#interface ethernet 0/2/1
Brocade(config-if-e10000-0/2/1)#rate-limit input fixed 1000000
Rate Limiting on Port 0/2/1 - Config: 1000000 Kbps, Actual: 1000000 Kbps
```

The above commands configure a fixed rate limiting policy that allows port 0/2/1, a 10-GbE port, to receive a maximum of 1000000 kilobits per second. If the port receives additional bits during a given one-second interval, the port drops all inbound packets on the port until the next one-second interval starts.

```
Brocade(config)#interface ethernet 0/1/10
Brocade(config-if-e1000-0/1/10)#rate-limit input fixed 1000
Rate Limiting on Port 0/1/10 - Config: 1000 Kbps, Actual: 1000 Kbps
```

The above commands configure a fixed rate limiting policy that allows port 0/1/10, a GbE port, to receive a maximum of 1000 kilobits per second. If the port receives additional bits during a given one-second interval, the port drops all inbound packets on the port until the next one-second interval starts.

Syntax: `[no] rate-limit input fixed <average-rate>`

The `<average-rate>` parameter specifies the maximum number of kilobits per second (Kbps) the port can receive. [Table 324](#) lists the minimum and maximum rates.

Fixed rate limiting on outbound port configuration

NOTE

This feature is not supported on FastIron X Series and Brocade FCX Series devices.

Outbound rate limiting allows you to specify the maximum number of kilobits a given port can transmit.

Brocade devices support the following types of outbound fixed rate limiting on Gbps and 10 Gbps Ethernet ports.

- **Port-based** – Limits the rate of outbound traffic on an individual physical port or trunk port, to a specified rate. Traffic that exceeds the maximum rate is dropped. Only one port-based outbound rate limiting policy can be applied to a port.
- **Port- and priority-based** – Limits the rate on an individual 802.1p priority queue on an individual physical port or trunk port. Traffic that exceeds the rate is dropped. Only one priority-based rate limiting policy can be specified per priority queue for a port. This means that a maximum of eight port- and priority-based policies can be configured on a port.

Minimum and maximum outbound rate limits

[Table 325](#) lists the minimum and maximum outbound rate limits on GbE and 10-GbE ports.

TABLE 325 Rates for outbound rate limiting

Port type	Minimum rate	Maximum rate	Granularity
GbE	65 Kbps	1000000 Kbps	65 Kbps
10-GbE	2500 Kbps	10000000 Kbps	2500 Kbps

Configuration notes for outbound rate limiting

- Outbound rate limiting is supported on:
 - GbE ports
 - 10-GbE ports
 - Trunk ports
- Outbound rate limiting is not supported on:
 - Ports on which LACP is enabled
 - Virtual interfaces
 - Loopback interfaces

- This feature is not supported on FastIron X Series and Brocade FCX Series devices.
- Because of the hardware architecture, the effect of outbound rate limiting differs on GbE ports compared to 10-GbE ports. For example, applying the same rate limiting value on GbE and 10-GbE ports will produce different results.
- You can configure both outbound port-base rate limiting and outbound port- and priority-based rate limiting on a single physical port or trunk port. However, if a priority-based limit for a given port is greater than the port-based rate limit, then the port-based rate limit will override the priority-based rate limit. Similarly, if the port-based rate limit is greater than the priority-based limit, then the priority-based rate limit will override the port-based rate limit.

Configuring port-based fixed rate limiting

To configure port-based fixed rate limiting on an outbound port, enter commands such as the following.

```
Brocade(config)#interface ethernet 0/1/34
Brocade(config-if-e1000-0/1/34)#rate-limit output fixed 32
Outbound Rate Limiting on Port 0/1/34 Config: 32 Kbps, Actual: 65 Kbps
```

The above commands configure a fixed rate limiting policy that allows port 0/1/34 to transmit 32 Kbps. Since port 0/1/34 is a GbE port and the minimum rate is 65 Kbps (refer to [Table 325](#)), the system will adjust the configured rate of 32 Kbps to an actual rate to 65 Kbps. If the port transmits additional bits during a given one-second interval, the port will drop all outbound packets on the port until the next one-second interval starts.

```
Brocade(config)#interface ethernet 0/2/1
Brocade(config-if-e1000-0/2/1)#rate-limit output fixed 32
Outbound Rate Limiting on Port 0/2/1 Config: 32 Kbps, Actual: 2500 Kbps
```

The above commands configure a fixed rate limiting policy that allows port 0/2/1 to transmit 32 Kbps per second. Since port 0/2/1 is a 10-GbE port and the minimum rate is 2500 Kbps (refer to [Table 325](#)), the system will adjust the configured rate of 32 Kbps to an actual rate of 2500 Kbps. If the port transmits additional bits during a given one-second interval, the port will drop all outbound packets on the port until the next one-second interval starts.

Syntax: `[no] rate-limit output fixed <average-rate>`

The `<average-rate>` parameter specifies the average number of kilobits per second (Kbps) the port can send. [Table 325](#) lists the minimum and maximum rates for GbE and 10-GbE ports.

Configuring port- and priority-based rate limiting

Port- and priority-based rate limiting limits the rate on an individual 802.1p priority queue on an individual physical port or trunk port.

To configure port- and priority-based fixed rate limiting on an outbound port, enter commands such as the following.

```
Brocade(config)#interface ethernet 0/1/35
Brocade(config-if-e1000-0/1/35)#rate-limit output fixed 1000 priority 7
Outbound Rate Limiting on Port 0/1/35 for Priority 7
Config: 1000 Kbps, Actual: 975 Kbps
```

The above commands configure a fixed rate limiting policy that allows traffic with a priority of 7 on port 0/1/35 to transmit 1000 Kbps per second. The system rounds the configured rate to 975 Kbps. If the port transmits additional bits during a given one-second interval, the port will drop all outbound packets on the port until the next one-second interval starts.

ACL-based rate limiting policy configuration

Brocade devices support IP ACL-based rate limiting of inbound traffic. ACL-based rate limiting provides the facility to limit the rate for IP traffic that matches the permit conditions in extended IP ACLs.

To configure ACL-based rate limiting, you create individual **traffic policies**, then reference the traffic policies in one or more ACL entries (also called clauses or statements). The traffic policies become effective on ports to which the ACLs are bound.

For configuration procedures for ACL-based rate limiting, refer to [Chapter 42, “Traffic Policies”](#).

Displaying the fixed rate limiting configuration

You can display the fixed rate limiting configuration for inbound and outbound traffic.

Inbound ports

To display the fixed rate limiting configuration on inbound ports, enter the **show rate-limit input** command.

```
Brocade#show rate-limit input
Total rate-limited interface count: 11.
Port      Configured Input Rate      Actual Input Rate
1         1000000                    1000000
3         10000000                   10005000
7         10000000                   10000000
9         7500000                    7502000
11        8000000                    7999000
12        8000000                    7999000
13        8000000                    7999000
14        8000000                    7999000
15        8000000                    7999000
21        8000000                    8000000
25        7500000                    7502000
```

Syntax: show rate-limit input

The command lists the ports on which fixed rate limiting is configured, and provides the information listed in [Table 326](#) for each of the ports.

TABLE 326 CLI display of Fixed rate limiting information on inbound ports

Field	Description
Total rate-limited interface count	The total number of ports that are configured for Fixed rate limiting.
Port	The port number.
Configured Input Rate	The maximum rate requested for inbound traffic. The rate is measured in bits per second (bps).
Actual Input Rate	The actual maximum rate provided by the hardware. The rate is measured in bps.

Displaying fixed rate limiting configuration on outbound ports

To display the fixed rate limiting configuration on outbound ports, enter the **show rate-limit fixed output** command.

```
Brocade#show rate-limit fixed output
Outbound Rate Shaping Limits in Kbps:
Port      PortMax  Prio0  Prio1  Prio2  Prio3  Prio4  Prio5  Prio6  Prio7
  1        1000000
  3        1000000
  7        1000000
  9         750000
 11         800000
 12         800000
 13         800000
 14         800000
 15         800000
 21         800000
 25         750000
```

Syntax: show rate-limit fixed output

The command lists the ports on which fixed rate limiting is configured, and provides the information listed in [Table 326](#) for each of the ports.

TABLE 327 CLI display of Fixed rate limiting information on outbound ports

Field	Description
Port	The port number.
PortMax	The maximum rate requested for outbound traffic. The rate is measured in bits per second (bps).
Prio0 – Prio7	The port- and priority-based rate limit maximum provided by the hardware. The rate is measured in bps.

Displaying the fixed rate limiting configuration

Quality of Service

Table 328 lists the individual Brocade FastIron switches and the Quality of Service (QoS) features they support. These features are supported in the Layer 2, base Layer 3, edge Layer 3, and full Layer 3 software images, except where explicitly noted.

TABLE 328 Supported QoS features

Feature	FESX FSX 800 FSX 1600	FWS	FCX	ICX 6610	ICX 6430 ICX 6450
802.1p Quality of Service (QoS):	Yes	Yes	Yes	Yes	Yes
<ul style="list-style-type: none"> • Strict Priority (SP) • Weighted Round Robin (WRR) • Combined SP and WRR • 8 priority queues 					
802.1p priority override	Yes	Yes	Yes	Yes	Yes
802.1p marking	Yes	Yes	Yes	Yes	Yes
DiffServ support	Yes	Yes	Yes	Yes	Yes
DSCP-based QoS	Yes	Yes	Yes	Yes	Yes
QoS mappings	Yes	Yes	Yes	Yes	Yes
User-configurable scheduler profiles	No	No	Yes	Yes	Yes

QoS overview

Quality of Service (QoS) features are used to prioritize the use of bandwidth in a switch. When QoS features are enabled, traffic is classified as it arrives at the switch, and processed through on the basis of configured priorities. Traffic can be dropped, prioritized for guaranteed delivery, or subject to limited delivery options as configured by a number of different mechanisms.

This chapter describes how QoS is implemented and configured in FastIron devices.

Classification is the process of selecting packets on which to perform QoS, reading the QoS information, and assigning a priority to the packets. The classification process assigns a priority to packets as they enter the switch. These priorities can be determined on the basis of information contained within the packet or assigned to the packet as it arrives at the switch. Once a packet or traffic flow is classified, it is mapped to a forwarding priority queue.

Packets on Brocade devices are classified in up to eight traffic classes with values from 0 to 7. Packets with higher priority classifications are given a precedence for forwarding.

Processing of classified traffic

The *trust level* in effect on an interface determines the type of QoS information the device uses for performing QoS. The Brocade device establishes the trust level based on the configuration of various features and whether the traffic is switched or routed. The trust level can be one of the following:

- Ingress port default priority.
- Static MAC address.
- Layer 2 Class of Service (CoS) value – This is the 802.1p priority value in the Ethernet frame. It can be a value from 0 through 7. The 802.1p priority is also called the *Class of Service*.
- Layer 3 Differentiated Services Code Point (DSCP) – This is the value in the six most significant bits of the IP packet header 8-bit DSCP field. It can be a value from 0 through 63. These values are described in RFCs 2472 and 2475. The DSCP value is sometimes called the *DiffServ value*. The device automatically maps the DSCP value of a packet to a hardware forwarding queue. Refer to “[Viewing QoS settings](#)” on page 1992.
- ACL keyword – An ACL can also prioritize traffic and mark it before sending it along to the next hop. This is described under “[QoS options for IP ACLs](#)” on page 1740.

Given the variety of different criteria, there are many possibilities for traffic classification within a stream of network traffic. For this reason, the priority of packets must be resolved based on which criteria takes precedence. Precedence follows the schemes illustrated in [Figure 220](#) through [Figure 222](#).

Determining the trust level of a packet

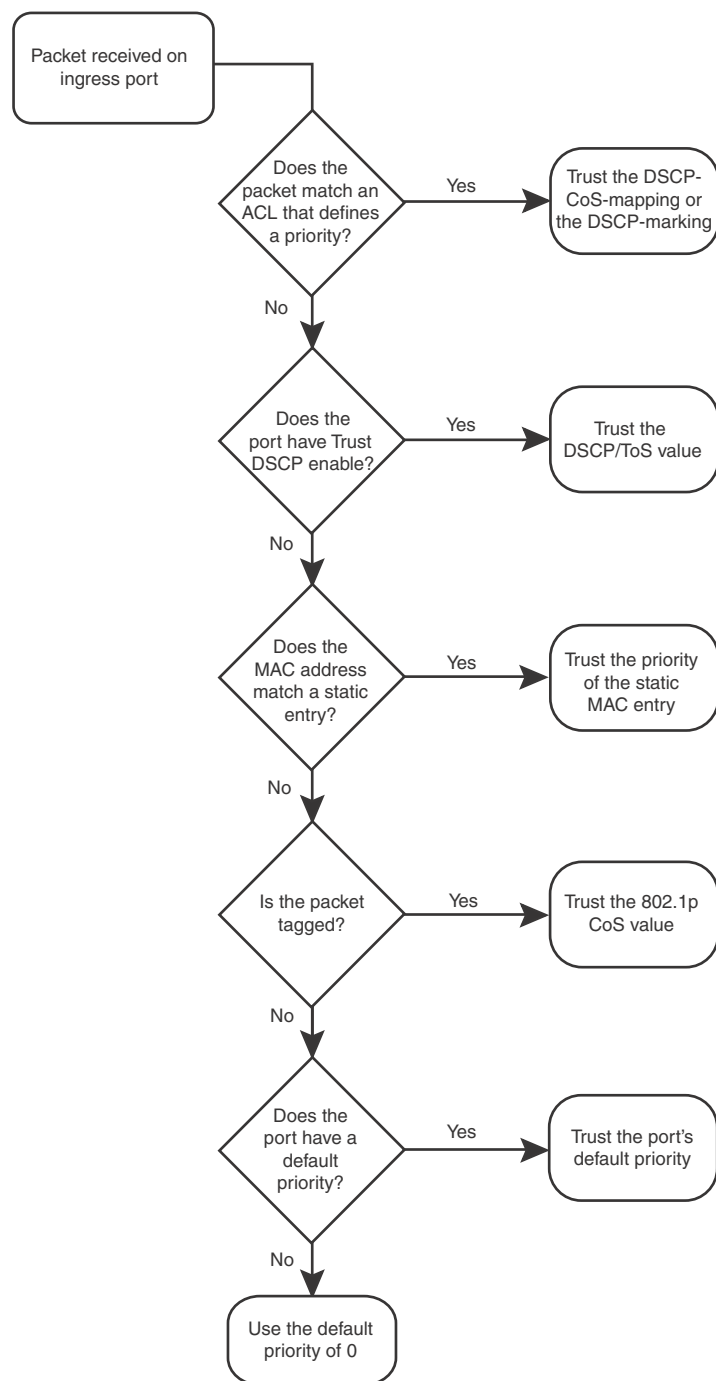

Packet trust level is determined differently on FastIron X Series devices than on FastIron WS and Brocade FCX and ICX series devices.

[Figure 220](#) illustrates how FastIron X Series devices determine the trust level of a packet.

NOTE

[Figure 220](#) is not applicable to the 48-port 10/100/1000 Mbps Ethernet POE interface module (SX-FI48GPP). To determine the trust level of a packet for the SX-FI48GPP interface module, refer to [Figure 221](#).

As shown in the flowchart, the first criteria considered is whether the packet matches on an ACL that defines a priority. Next, it checks if trust DSCP is enabled on the port. If this is not the case, the packet is next classified based on the static MAC address. If this is not true and the packet is tagged, the packet is classified with the 802.1p CoS value. If none of these is true, the packet is next classified based on the ingress port default priority or the default priority of zero (0).

FIGURE 220 Determining a packet trust level - FastIron X Series devices

[Figure 221](#) on page 1967 illustrates how the SX-FI48GPP interface module determines the trust level of a packet. The marking process for the SX-FI48GPP interface module is similar to the marking process for other FastIron SX modules. However, there are major differences between the SX-FI48GPP interface module and other FastIron SX modules.

- For the SX-FI48GPP interface module, static MAC priority takes higher precedence than VLAN priority. For other FastIron SX modules, VLAN priority takes higher precedence over static MAC priority.
- For other FastIron SX modules, the priority of the dynamically learned MAC address is inherited from the default port priority. For the SX-FI48GPP interface module, the priority of the dynamically learned MAC address is not inherited from the default port priority because it is not desirable to allow the port priority to take precedence over the VLAN priority. All dynamically learned MAC addresses are assigned a priority of 0 in the SX-FI48GPP interface module. Therefore, configuring a static MAC with a priority of 0 has no effect on QoS marking.

FIGURE 221 Determining a packet trust level - SX-FI48GPP, SX-FI-24GPP, SX-FI-24HF, SX-FI-2XG, and SX-FI-8XG modules

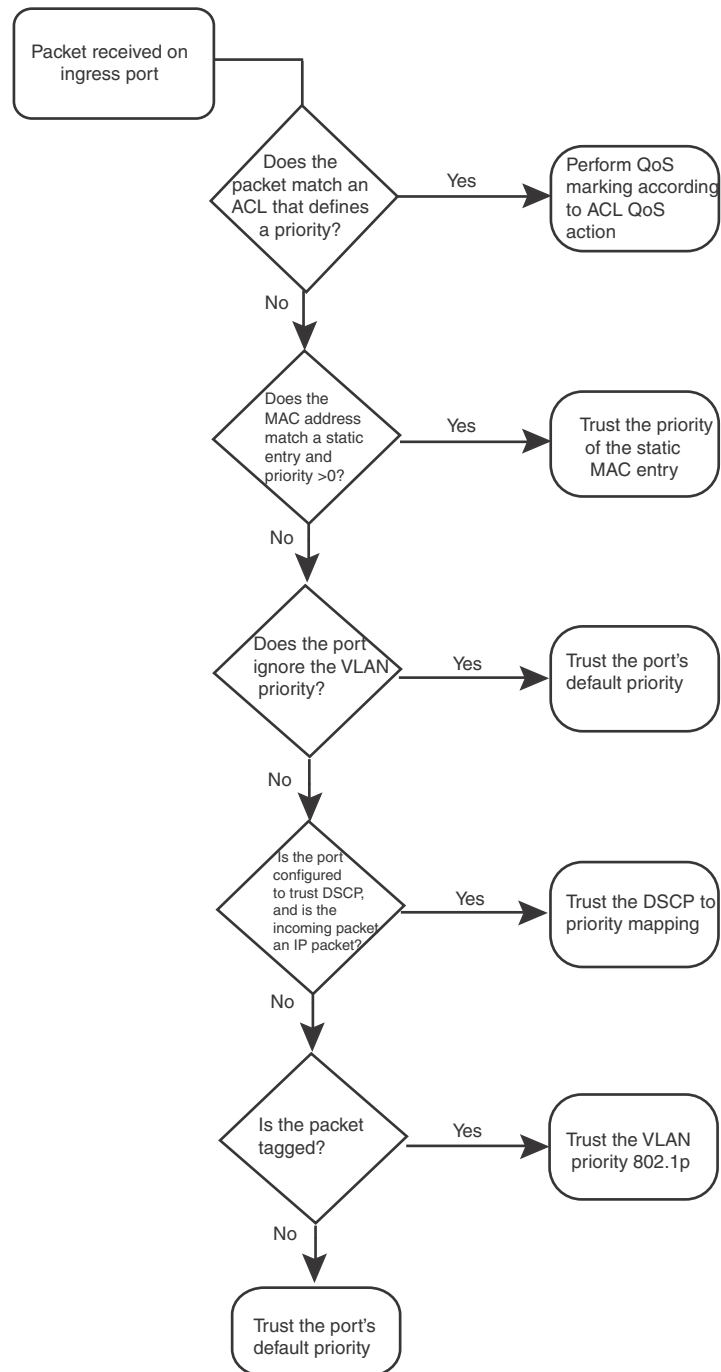

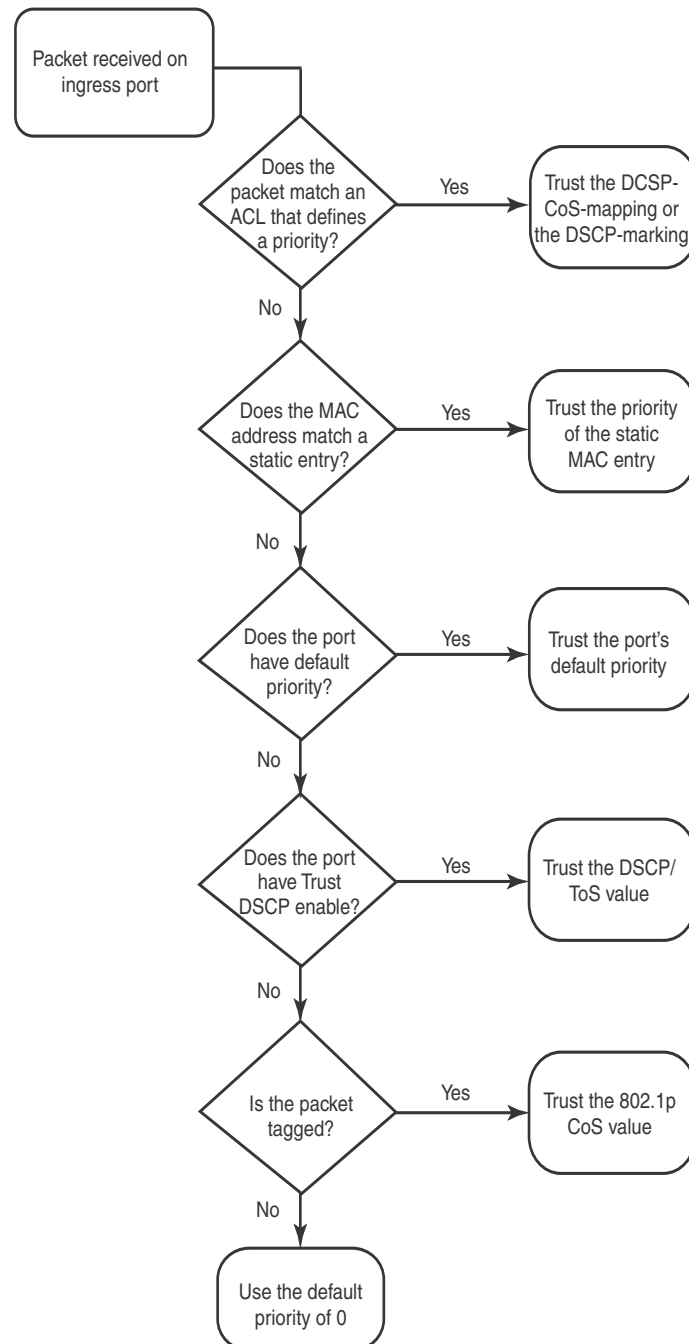

Figure 222 illustrates how FastIron WS and Brocade FCX and ICX series devices determine the trust level of a packet. As shown in the flowchart, the first criteria considered is whether the packet matches on an ACL that defines a priority. If this is not the case and the MAC address of the packet matches a static entry, the packet is classified with the priority of the static MAC entry. If neither of these is true, the packet is next classified with the ingress port default priority. then DSCP/ToS value, then 802.1p CoS value, and finally the default priority of zero (0).

FIGURE 222 Determining a packet trust level - FastIron WS and Brocade FCX Series and ICX devices

Once a packet is classified, it is mapped to a forwarding queue. For all products except the SX-FI48GPP interface module and ICX 6430 switch, there are eight queues designated from 0 through 7. The internal forwarding priority maps to one of these eight queues. For the SX-FI48GPP interface module and ICX 6430 switch, internal forwarding priority maps to four forwarding queues. The mapping between the internal priority and the forwarding queue cannot be changed.

Table 329 through Table 332 show the default QoS mappings for FCX platforms that are used if the trust level for CoS or DSCP is enabled. For information on the SX-FI48GPP interface module, refer to “Queues for the SX-FI48GPP interface module” on page 1972. For information on default QoS mappings for the ICX 6430 switch, refer to “Queues for the ICX 6430 switch” on page 1973.

TABLE 329 Default QoS mappings for FCX platforms, columns 0 to 15

DSCP value	0	1	2	3	4	5	6	7	8	9	10	11	12	12	14	15

TABLE 331 Default QoS mappings for FCX platforms, columns 32 to 47

DSCP value	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47
802.1p (CoS) value	4	4	4	4	4	4	4	4	5	5	5	5	5	5	5	5
DSCP value	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47
Internal forwarding priority	4	4	4	4	4	4	4	4	5	5	5	5	5	5	5	5
Forwarding queue	4	4	4	4	4	4	4	4	5	5	5	5	5	5	5	5

TABLE 332 Default QoS mappings for FCX platforms, columns 48 to 63

DSCP value	48	49	50	51	52	53	54	55	56	57	58	59	60	61	62	63
802.1p (CoS) value	6	6	6	6	6	6	6	6	7	7	7	7	7	7	7	7
DSCP value	48	49	50	51	52	53	54	55	56	57	58	59	60	61	62	63
Internal forwarding priority	6	6	6	6	6	6	6	6	7	7	7	7	7	7	7	7
Forwarding queue	6	6	6	6	6	6	6	6	7	7	7	7	7	7	7	7

Mapping between the DSCP value and forwarding queue cannot be changed. However, mapping between DSCP values and other properties can be changed as follows:

- DSCP to internal forwarding priority mapping – You can change the mapping between the DSCP value and the internal forwarding priority value from the default values shown in [Table 329](#) through [Table 332](#). This mapping is used for CoS marking and determining the internal priority when the trust level is DSCP. Refer to [“Changing the DSCP to internal forwarding priority mappings”](#) on page 1984.
- VLAN priority (802.1p) to hardware forwarding queue - You can change the mapping between the 802.1p value and hardware forwarding queue from the default value. Refer to [“Changing the VLAN priority 802.1p to hardware forwarding queue mappings”](#) on page 1985.

QoS for Brocade stackable devices

Brocade FastIron units in an IronStack support QoS. Units in a stack communicate the stack topology information and other proprietary control information through the stacking links. For more information about stacking links and IronStack technology, refer to [Chapter 7, “Brocade Stackable Devices”](#).

In addition to control information, the stacking links also carry user network data packets. In an IronStack topology, the priority of stacking-specific control packets is elevated above that of data path packets, preventing loss of control packets, and timed retries that affect performance. This prioritization also prevents stack topology changes that may occur if enough stack topology information packets are lost.

IronStack technology reserves one QoS profile to provide a higher priority for stack topology and control traffic.

QoS profile restrictions in an IronStack

In a stacking topology, because CoS level 7 is reserved for stacking, quality profiles for qosp7 cannot be configured. If an attempt is made to configure a profile for qosp7, the system ignores the configuration.

NOTE

This applies only when the device is operating in stacking mode. It does not apply to stand-alone devices.

QoS behavior for trusting Layer 2 (802.1p) in an IronStack

By default, Layer 2 trust is enabled. Because priority 7 is reserved for stacking control packets, any ingress data traffic with priority 7 is mapped to internal hardware queue 6. All other priorities are mapped to their corresponding queues.

QoS behavior for trusting Layer 3 (DSCP) in an IronStack

When the trust dscp mode is enabled, packets arriving with DSCP values 56 to 63 are mapped to internal hardware queue 6. All other DSCP values are mapped to their corresponding internal hardware queues.

QoS behavior on port priority and VLAN priority in an IronStack

Port priority has a higher precedence than the 802.1p priority examination. If port priority is set to 7, all incoming traffic is mapped to internal hardware queue 6.

When stacking is not enabled on a device, all priorities are mapped to their corresponding queues without restrictions.

QoS behavior for 802.1p marking in an IronStack

By default when stacking mode is enabled, 802.1p marking is enabled. Outgoing tagged traffic is marked with 802.1p in the VLAN tag based on the internal hardware queue into which ingress traffic was classified. As an exception, QoS priority 7 mapped to priority 6 will have the marking for hardware queue 7.

When stacking mode is disabled, outgoing traffic is not marked with 802.1p based on the internal hardware queue.

QoS queues

Brocade devices support the eight QoS queues (qosp0 through qosp7) listed in [Table 333](#).

TABLE 333 QoS queues

QoS priority level	QoS queue
0	qosp0 (lowest priority queue)
1	qosp1
2	qosp2
3	qosp3
4	qosp4
5	qosp5
6	qosp6
7	qosp7 (highest priority queue)

The queue names listed in [Table 333](#) are the default names. If desired, you can rename the queues as shown in [“Renaming the queues”](#) on page 1989.

Packets are classified and assigned to specific queues based on the criteria shown in [Figure 220](#), [Figure 221](#), and [Figure 222](#).

For FCX and ICX devices, ingress packets are classified into the eight priorities, which map to eight hardware queues or traffic classes (TCs) based on the priority. Exceptions to this model are the SX-FI48GPP and SX-FI-8XG interface modules and the ICX 6430 switch as explained in the following sections.

Queues for the SX-FI48GPP interface module

The SX-FI48GPP interface module consists of two separate hardware Network Processors (NPs). The front-end NP supports four hardware queues, and the back-end NP supports eight hardware queues. Ingress packets are classified into eight priorities mapped into four hardware queues. In the egress, traffic is destined to two adjacent network ports (for example, ports 1/1 and 1/2), and aggregated into one 1-GbE port in the back-end NP. The two network ports share the same hardware queues, and therefore they have the same buffer and descriptor limits and scheduling algorithm for transmission.

Ingress packets are classified into eight QoS priority levels at the front-end NP of the SX-FI48GPP module. The eight priorities are mapped into four hardware queues based on the priority queue configuration in [Table 334](#). QoS priority 7 is the highest priority, and QoS 0 is the lowest priority.

TABLE 334 Priority queues for the SX-FI48GPP

QoS priority level	Hardware queues (traffic classes)
0	0
1	0
2	1
3	1
4	2
5	2
6	3
7	3

QoS classification occurs in two iterations; initially in the front-end NP, followed by the back-end NP. The back-end NP has the same classification and marking capabilities of existing FastIron SX interface modules, but the front-end NP does not support ACL and static MAC priority. The front-end NP supports basic QoS features, such as port priority, QoS-ToS mapping, 802.1p to priority mapping, 802.1p override, and trust DSCP mode.

The default scheduling configuration for Weighted Round Robin (WRR), Hybrid WRR and Strict Priority (SP), and SP mode for the eight QoS priority queues mapped to the four hardware queues is described under [“Default scheduling configuration for the SX-FI48GPP module”](#) on page 1985.

Queues for the SX-FI-8XG interface module

The SX-FI-8XG interface module consists of two separate hardware Network Processors (NP). The front-end NP supports 8 hardware queues, and the back-end NP supports eight hardware queues. In the egress, traffic is destined to four adjacent ports (for example, ports 1/1 to 1/4), and aggregated into one 10GbE port in the back-end NP. The four network ports share the same hardware queues; therefore, they have the same buffer and descriptor limits and scheduling algorithm for transmission.

QoS classification occurs in two iterations; initially in the front-end NP, followed by the back-end NP. The back-end NP has the same classification and marking capabilities of existing FastIron SX interface modules, however, the front -end NP does not support ACL and static MAC priority. The front-end NP supports basic QoS features, such as port priority, qos-tos mapping, 802.1p to priority mapping, 802.1p override, and trust-dscp mode.

Queues for the ICX 6430 switch

For the ICX 6430 switch, ingress packets are classified into eight QoS priority levels. These are mapped internally to four hardware forwarding queues or traffic classes as shown in [Table 335](#). QoS priority 7 is the highest priority, and QoS 0 is the lowest QoS priority (qosp) level.

TABLE 335 Priority queues for the ICX 6430

QoS priority level	Hardware queues (Traffic classes)
0	0
1	0
2	1
3	1
4	1
5	2
6	2
7	3

For the ICX 6430 switch, internal forwarding priority maps to hardware forwarding queues 0 through 3. The mapping between the internal priority and hardware forwarding queue cannot be changed. [Table 336](#) through [Table 339](#) shows the default QoS mappings that are used if the trust level for CoS or DSCP is enabled. Mappings are the same for stand-alone and stacking systems.

TABLE 336 Default QoS mappings for ICX 6430, columns 0 to 15

DSCP value	0	1	2	3	4	5	6	7	8	9	10	11	12	12	14	15
802.1p (CoS) value	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
DSCP value	0	1	2	3	4	5	6	7	8	9	10	11	12	12	14	15

TABLE 336 Default QoS mappings for ICX 6430, columns 0 to 15 (Continued)

Forwarding queue	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

TABLE 337 Default QoS mappings for ICX 6430, columns 16 to 31

DSCP value	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
802.1p (CoS) value	2	2	2	2	2	2	2	2	3	3	3	3	3	3	3	3
DSCP value	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
Internal forwarding priority	2	2	2	2	2	2	2	2	3	3	3	3	3	3	3	3
Forwarding queue	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

TABLE 338 Default QoS mappings for ICX 6430, columns 32 to 47

DSCP value	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47
802.1p (CoS) value	4	4	4	4	4	4	4	4	5	5	5	5	5	5	5	5
DSCP value	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47
Internal forwarding priority	4	4	4	4	4	4	4	4	5	5	5	5	5	5	5	5
Forwarding queue	1	1	1	1	1	1	1	1	2	2	2	2	2	2	2	2

TABLE 339 Default QoS mappings for ICX 6430, columns 48 to 63

DSCP value	48	49	50	51	52	53	54	55	56	57	58	59	60	61	62	63
802.1p (CoS) value	6	6	6	6	6	6	6	6	7	7	7	7	7	7	7	7
DSCP value	48	49	50	51	52	53	54	55	56	57	58	59	60	61	62	63
Internal forwarding priority	6	6	6	6	6	6	6	6	7	7	7	7	7	7	7	7
Forwarding queue	2	2	2	2	2	2	2	2	3	3	3	3	3	3	3	3

Mapping between DSCP value and forwarding queue cannot be changed. However, mapping between DSCP values and other properties can be changed as follows:

- DSCP to internal forwarding priority mapping – You can change the mapping between the DSCP value and the internal forwarding priority value from the default values shown in [Table 336](#) through [Table 339](#). This mapping is used for CoS marking and determining the internal priority when the trust level is DSCP. Refer to [“Changing the DSCP to internal forwarding priority mappings”](#) on page 1984.
- VLAN priority (802.1p) to hardware forwarding queue - You can change the mapping between the 802.1p value and hardware forwarding queue from the default value. Refer to [“Changing the VLAN priority 802.1p to hardware forwarding queue mappings”](#) on page 1985

User-configurable scheduler profile

The user-configurable scheduler profile is a template that defines either the scheduling mechanism or scheduling profile (weights assigned to the queues) or both for the egress queues. A configured user-configurable scheduler profile for egress queues can be applied to any hardware device. The default QoS is applicable to the entire system. If the scheduler profile is configured using the `qos mech strict` command, all devices in the system will be configured with the strict priority. The user-configurable scheduler profile is applicable only to the specific devices, leaving the remaining devices running default QoS. On any device, the user-configurable scheduler profile has high priority over the default QoS. On any device, user-configurable scheduler profile has high priority over the default QoS. The user-configurable scheduler profile should be in line with default QoS commands in both stacking and stand-alone systems.

User-configurable scheduler profile configuration

Configuring a user-configurable scheduler profile involves, selecting a proper mechanism and appropriate weights for the traffic classes (TCs) corresponding to that mechanism. It is highly recommended that you let the system use the default scheduling mechanism unless user knows what parameters you intend to modify and for what reasons.

There are two ways of creating a user-configurable scheduler profile. The scheduler-profile can be created either by specifying a mechanism (WRR, Strict, or Mixed) or by specifying weights.

The user-configurable scheduler profile can be created by specifying a mechanism. There are three available mechanisms:

- Strict Priority (SP)
- Weighted Round Robin (WRR)
- Mixed (combination of SP and WRR)

Following is the command format for creating a profile while specifying a mechanism.

qos scheduler-profile <user_profile_name> **mechanism** <scheduling_mechanism>

Syntax: :

The <user_profile_name> variable is the name of the profile you are creating.

The <scheduling_mechanism> variable is SP, WRR or Mixed.

The user-configurable scheduler profile can be created by specifying weights from **qosp0** through **qosp7** as shown in the following command format.

qos scheduler-profile <user_profile_name> **profile** **qosp0** <w0> **qosp7** <w7>

Syntax:

The `<user_profile_name>` variable is the name of the profile you are creating.

Profile **qosp0** through **qosp7** are the default queue names.

The `<w0>` through `<w7>` variables are the assigned weights.

If you create a profile specifying only the weights (**qosp0** through **qosp7**) without specifying the mechanism, the default mechanism is used. The default mechanism for stacking systems is **Mixed**, and **WRR** for stand-alone systems.

If you change the profile mechanism, the weights also get changed according to the mechanism. The weights can be modified according to the following requirements:

- If the mechanism is changed to **WRR**, the default system weights get assigned
- If the mechanism is changed to **Mixed**, the default mix weights get assigned
- If the mechanism is changed to **Strict**, the weights are ignored and remain untouched.

Scheduler-profile modifications take effect dynamically on an active profile. The operational defaults for all scheduling types for stacking and stand-alone systems are listed in [Table 340](#).

Displaying the user-configurable scheduler profile configuration

To display the specified user-configurable scheduler profile configuration, use the **show scheduler-profile** `<user_profile_name>` command.

Syntax:

The `<user_profile_name>` variable is the name of the profile you are creating.

To display all the scheduler profiles configured in the runtime configuration for the system, use the **show scheduler-profile all** command.

FCX and ICX 6450 platforms

[Table 340](#) shows the default values for the scheduling type for stacking and stand-alone FCX and ICX 6450 platforms.

TABLE 340 Default values for scheduling type for stacking and stand-alone systems (for FCX and ICX 6450 platforms).

Stacking system (common for FCX platforms)

Traffic Class	SP	SP Jumbo	WRR	WRR Jumbo	Mixed	Mixed Jumbo
TC0	SP	SP	3	8	15	15
TC1	SP	SP	3	8	15	15
TC2	SP	SP	3	8	15	15
TC3	SP	SP	3	8	15	15
TC4	SP	SP	3	8	15	15
TC5	SP	SP	10	16	25	25
TC6	SP	SP	75	44	SP	SP
TC7	SP	SP	SP	SP	SP	SP

Stand-alone system (common for FCX platforms)

	SP	SP Jumbo	WRR	WRR Jumbo	Mixed	Mixed Jumbo
TC0	SP	SP	3	8	15	15
TC1	SP	SP	3	8	15	15
TC2	SP	SP	3	8	15	15
TC3	SP	SP	3	8	15	15
TC4	SP	SP	3	8	15	15
TC5	SP	SP	3	8	25	25
TC6	SP	SP	7	8	SP	SP
TC7	SP	SP	75	44	SP	SP

ICX 6430 platforms

[Table 340](#) shows the default values for scheduling type for stacking and stand-alone ICX 6430 platforms. The lowest weighted priority is for qosp0, while the highest is for qosp7.

Note that values are provided for QoS priority (QSP) levels. The weights applied to the traffic class (TC) are the sum of the weights of the QSP levels that map to that TC. For example, QSP0 and QSP1 map to TC0. If the weight for QSP0 is 6 and the weight for QSP1 is 6, then the weight for TC0 is 12. Refer to [Table 335](#) on page 1973 for QoS priority to traffic class mapping.

TABLE 341 Default values for scheduling type for stacking and stand-alone systems (for ICX 6430 platforms)

Stacking System for scheduling type for stacking and stand-alone systems (for ICX 6430 platforms)

QSP Level	SP	SP Jumbo	WRR	WRR Jumbo	Mixed	Mixed Jumbo
QSP0	SP	SP	3	8	15	15
QSP1	SP	SP	3	8	15	15
QSP2	SP	SP	3	8	15	15
QSP3	SP	SP	3	8	15	15
QSP4	SP	SP	3	8	40	40
QSP5	SP	SP	10	16	SP	SP
QSP6	SP	SP	75	44	SP	SP

Stand-alone system for ICX 6430 platforms (Continued)

QSP6	SP	SP	7	8	SP	SP
QSP7	SP	SP	75	44	SP	SP

QoS priorities-to-traffic assignment

By default, all traffic is in the best-effort queue (qosp0) and is honored on tagged ports on all FastIron switches. You can assign traffic to a higher queue based on the following:

- Incoming port (sometimes called the *ingress port*)
- Static MAC entry

When you change the priority, you specify a number from 0 through 7. The priority number specifies the IEEE 802.1 equivalent to one of the eight QoS queues on Brocade devices. The numbers correspond to the queues as shown in [Table 333](#).

Although it is possible for a packet to qualify for an adjusted QoS priority based on more than one of the criteria, the system always gives a packet the highest priority for which it qualifies. Thus, if a packet is entitled to the premium queue because of its IP source and destination addresses, but is entitled only to the high queue because of its incoming port, the system places the packet in the premium queue on the outgoing port.

Changing a port priority

To change the QoS priority of port 1/1 to the premium queue (qosp7), enter the following commands.

```
Brocade(config)#interface ethernet 1/1
Brocade(config-if-e1000-1/1)#priority 7
```

The device assigns priority 7 to untagged switched traffic received on port 1/1.

Use the following command to assign priority levels.

[no] priority <num>

Syntax:

The <num> variable can be from 0 through 7 and specifies the IEEE 802.1 equivalent to one of the eight QoS queues listed in [Table 333](#).

Assigning static MAC entries to priority queues

By default, all MAC entries are in the best-effort queue. When you configure a static MAC entry, you can assign the entry to a higher QoS level.

To configure a static MAC entry and assign the entry to the premium queue, enter commands such as the following.

```
Brocade(config)#vlan 9
Brocade(config-vlan-9)#static-mac-address 1145.1163.67FF ethernet 1/1 priority 7
Brocade(config-vlan-9)#write memory
```

Use the following command to configure a MAC entry and assign the entry to a priority queue.

[no] **static-mac-address** <mac-addr> **ethernet** <port> [priority <num>]

Syntax:

The <mac-addr> is the MAC address.

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

The **priority** <num> variable can be from 0 through 7 and specifies the IEEE 802.1 equivalent to one of the eight QoS queues.

NOTE

The location of the **static-mac-address** command in the CLI depends on whether you configure port-based VLANs on the device. If the device does not have more than one port-based VLAN (VLAN 1, which is the default VLAN containing all ports), the **static-mac-address** command is at the global CONFIG level of the CLI. If the device has more than one port-based VLAN, then the **static-mac-address** command is not available at the global CONFIG level. In this case, the command is available at the configuration level for each port-based VLAN.

Buffer allocation and threshold for QoS queues

By default, Brocade IronWare software allocates a certain number of buffers to the outbound transport queue for each port based on QoS priority. The buffers control the total number of packets permitted in the outbound queue for the port. If desired, you can increase or decrease the maximum number of outbound transmit buffers allocated to all QoS queues, or to specific QoS queues on a port or group of ports. For more information, refer to [“Dynamic buffer allocation for QoS priorities for FastIron X Series devices”](#) on page 584.

802.1p priority override

You can configure a port to ignore the 802.1p priority for traffic classification for an incoming packet. When this feature is enabled, packets will be classified as follows:

- If the packet matches an ACL that defines the priority, then ACL priority will be used.
- If the packet source or destination MAC address matches a configured static MAC address with priority, then static MAC priority will be used.
- If the ingress port has a configured priority, then port priority will be used.
- If the other situations do not apply, the configured or default port priority (0) will be used.

Note that the original 802.1p priority in the packet will be retained. This feature does not re-mark the 802.1p value.

Configuration notes and feature limitations

- 802.1p priority override is supported on physical ports and trunk ports. When applied to the primary port of a trunk group, the configuration applies to all members of the trunk group.
- This feature is not supported together with trust dscp.

Enabling 802.1p priority override

To enable 802.1p priority override, enter the following command at the interface level of the CLI.

```
Brocade(config-if-e1000-2)#priority ignore-8021p
```

Syntax: [no] priority ignore-8021p

Use the following command to show whether 802.1p priority override is enabled on a port.

```
Brocade#show run interface ethernet 1
interface ethernet 1
    priority ignore-8021p
```

Syntax: show run interface ethernet <port>

Specify the *port* variable in one of the following formats:

- FWS, FCX, and ICX stackable switches – *stack-unit/slotnum/portnum*
- FSX 800 and FSX 1600 chassis devices – *slotnum/portnum*
- ICX devices – *slotnum/portnum*
- FESX compact switches – *portnum*

Marking

Marking is the process of changing the packet QoS information (the 802.1p and DSCP information in a packet) for the next hop. For example, for traffic coming from a device that does not support Differentiated Services (DiffServ), you can change the packet IP precedence value into a DSCP value before forwarding the packet.

You can mark a packet's Layer 2 CoS value, its Layer 3 DSCP value, or both values. The Layer 2 CoS or DSCP value the device marks in the packet is the same value that results from mapping the packet QoS value into a Layer 2 CoS or DSCP value.

Marking is optional and is disabled by default. Marking is performed using ACLs. When marking is not used, the device still performs the mappings listed in [“QoS overview”](#) on page 1963 for scheduling the packet, but leaves the packet QoS values unchanged when the device forwards the packet.

For configuration syntax, rules, and examples of QoS marking, refer to [“QoS options for IP ACLs”](#) on page 1740.

DSCP-based QoS configuration

Brocade IronWare releases support basic DSCP-based QoS (also called Type of Service (ToS)-based QoS) as described in this chapter. However, the FastIron family of switches does not support other advanced DSCP-based QoS features as described in the *Enterprise Configuration and Management Guide*.

Brocade IronWare releases also support marking of the DSCP value. The software can read Layer 3 Quality of Service (QoS) information in an IP packet and select a forwarding queue for the packet based on the information. The software interprets the value in the six most significant bits of the IP packet header 8-bit ToS field as a DSCP value, and maps that value to an internal forwarding priority.

The internal forwarding priorities are mapped to one of the eight forwarding queues (qosp0 through qosp7) on the Brocade device. During a forwarding cycle, the device gives more preference to the higher-numbered queues, so that more packets are forwarded from these queues. For example, queue qosp7 receives the highest preference, while queue qosp0, the best-effort queue, receives the lowest preference.

Application notes for DSCP-based QoS

- DSCP-based QoS is not automatically honored for routed and switched traffic. The default is 802.1p to CoS mapping. To honor DSCP-based QoS, you must either use an ACL or enable trust DSCP. Refer to [“Using ACLs to honor DSCP-based QoS”](#) on page 1981.
- When DSCP marking is enabled, the device changes the contents of the inbound packet ToS field to match the DSCP-based QoS value. This differs from BigIron, which marks the outbound packet ToS field.

Using ACLs to honor DSCP-based QoS

This section shows how to configure Brocade devices to honor DSCP-based QoS for routed and switched traffic.

FastIron stackable devices

FastIron WS and Brocade FCX Series devices support DSCP-based QoS on a per-port basis. DSCP-based QoS is not automatically honored for switched traffic. The default is 802.1p to CoS mapping. To honor DSCP-based QoS, enter the following command at the interface level of the CLI.

[no] trust dscp

To disable the configuration, use the no form of the command.

When trust dscp is enabled, the interface honors the Layer 3 DSCP value. By default, the interface honors the Layer 2 CoS value.

NOTE

The **trust dscp** command is not supported with 802.1p priority override.

FastIron X Series devices

FastIron X Series devices require the use of an ACL to honor DSCP-based QoS for routed traffic in the Layer 3 image, or for switched traffic in the Layer 2 image. To enable DSCP-based QoS on these devices, apply an ACL entry such as the following.

```
Brocade(config)#access-list 101 permit ip any any dscp-cos-mapping
```

NOTE

Use the **bridged-routed** keyword in the ACL to honor DSCP for switched traffic in the Layer 3 image. Refer to [“Enabling ACL support for switched traffic in the router image”](#) on page 1733.

NOTE

The **access-list 101 permit ip any any dscp-cos-mapping** command is supported on the SX-FI48GPP interface module. For more information on QoS queues for the SX-FI48GPP interface module, refer to [“Queues for the SX-FI48GPP interface module”](#) on page 1972.

Trust DSCP for the SX-FI48GPP, SX-FI-24GPP, SX-FI-24HF, SX-FI-2XG, and SX-FI8XG modules

On the following modules, trust DSCP can be enabled on a per-port basis:

- SX-FI48GPP
- SX-FI-24GPP
- SX-FI-24HF
- SX-FI-2XG
- SX-FI-8XG

Each port on the supported modules corresponds to a front-end panel port. By default, trust VLAN priority is enabled.

NOTE

For all ports in the other FastIron SX modules, ACL should be used to implement the trust DSCP mode.

For example, to enable trust DSCP on interface ethernet 1/48 on the SX-FI48GPP module, enter the following command.

[no] trust dscp

To disable the configuration, use the no form of the command.

Configuring QoS mapping configuration

You can optionally change the following QoS mappings:

- DSCP to internal forwarding priority
- VLAN priority (802.1p) to hardware forwarding queue

The mappings are globally configurable and apply to all interfaces.

Default DSCP to internal forwarding priority mappings

The DSCP values are described in RFCs 2474 and 2475. [Table 342](#) lists the default mappings of DSCP values to internal forwarding priority values.

TABLE 342 Default DSCP to internal forwarding priority mappings

Internal forwarding priority	DSCP value
0 (lowest priority queue)	0 – 7
1	8 – 15
2	16 – 23
3	24 – 31
4	32 – 39
5	40 – 47
6	48 – 55
7 (highest priority queue)	56 – 63

Notice that DSCP values range from 0 through 63, whereas the internal forwarding priority values range from 0 through 7. Any DSCP value within a given range is mapped to the same internal forwarding priority value. For example, any DSCP value from 8 through 15 maps to priority 1.

After performing this mapping, the device maps the internal forwarding priority value to one of the hardware forwarding queues.

On FWS, FCX, and ICX devices, you can use QoS queue 1 for priority traffic, even when sFlow is enabled on the port. This differs from the FastIron X Series devices, which support seven priorities for user data instead of eight when sFlow is enabled. QoS queue 1 is reserved for sFlow and not used by other packets. Any non-sFlow packets assigned to QoS queue 1 will be directed to QoS queue 0. Note that the ICX 6430 does not support sFlow.

[Table 343](#) lists the default mappings of internal forwarding priority values to the hardware forwarding queues for the ICX 6430.

TABLE 343 Default mappings of internal forwarding priority values for the ICX 6430

Internal forwarding priority	Forwarding queues
0 (lowest priority queue)	qosp0
1	qosp0
2	qosp1
3	qosp1
4	qosp1
5	qosp2
6	qosp2
7 (highest priority queue)	qosp3

You can change the DSCP to internal forwarding mappings. You also can change the internal forwarding priority to hardware forwarding queue mappings.

Changing the DSCP to internal forwarding priority mappings

To change the DSCP to internal forwarding priority mappings for all the DSCP ranges, enter commands such as the following at the global CONFIG level of the CLI.

```
Brocade(config)#qos-tos map dscp-priority 0 2 3 4 to 1
Brocade(config)#qos-tos map dscp-priority 8 to 5
Brocade(config)#qos-tos map dscp-priority 16 to 4
Brocade(config)#qos-tos map dscp-priority 24 to 2
Brocade(config)#qos-tos map dscp-priority 32 to 0
Brocade(config)#qos-tos map dscp-priority 40 to 7
Brocade(config)#qos-tos map dscp-priority 48 to 3
Brocade(config)#qos-tos map dscp-priority 56 to 6
```

Use the following command to map priority levels to DSCP values.

[no] qos-tos map dscp-priority <dscp-value> [<dscp-value> ...] to <priority>

Syntax:

The <dscp-value> [<dscp-value> ...] variable specifies the DSCP value ranges you are remapping.

You can specify up to eight DSCP values in the same command, to map to the same forwarding priority.

The <priority> variable specifies the internal forwarding priority.

Following is an example of using this command.

```
qos-tos map dscp-priority 1 2 3 4 5 6 7 8 to 6
```

Following is output displayed from using the **show qos-tos** command as a result of issuing the preceding command.

```
Brocade#show qos-tos
```

Portions of table omitted for simplicity.

DSCP-Priority map: (dscp = d1d2)

	d2	0	1	2	3	4	5	6	7	8	9
d1											
0		1	0	1	1	1	0	0	0	5	1
1		6	1	1	1	1	1	4	2	2	2
2		2	2	2	2	2	3	3	3	3	3
3		3	3	0	4	4	4	4	4	4	4
4		7	5	5	5	5	5	5	5	3	6
5		6	6	6	6	6	6	6	7	7	7
6		7	7	7	7						

This output displays mappings in the DSCP to forwarding priority portion of the QoS information display. To read this part of the display, select the first part of the DSCP value from the d1 column and select the second part of the DSCP value from the d2 row. For example, to read the DSCP to forwarding priority mapping for DSCP value 24, select 2 from the d1 column and select 4 from the d2 row. The mappings that are changed by the example **qos-tos map dscp-priority** command are shown below in bold type.

Changing the VLAN priority 802.1p to hardware forwarding queue mappings

To map a VLAN priority to a different hardware forwarding queue, enter commands such as the following at the global CONFIG level of the CLI.

```
[no] qos tagged-priority <num> <queue>
```

Syntax:

The <num> variable can be from 0 through 7 and specifies the VLAN priority.

The <queue> variable specifies the hardware forwarding queue to which you are reassigning the priority.

The default queue names are as follows:

- qosp7
- qosp6
- qosp5
- qosp4
- qosp3
- qosp2
- qosp1
- qosp0

Following is an example of using this command.

```
Brocade(config)#qos tagged-priority 2 qosp0
```

Default scheduling configuration for the SX-FI48GPP module

The default scheduling configuration for Weighted Round Robin (WRR), Strict Priority (SP), and mixed WRR and SP mode for the eight QoS priority (qosp) queues mapped to the four hardware queues is described in [Table 344](#).

TABLE 344 Default configuration for 8 to 4 queues for the SX-FI48GPP module

Hardware Queue	Weighted Round Robin (WRR) mode	Mixed WRR and SP	Strict Priority (SP) mode
3	Weight 82%	Strict Priority	Strict Priority
2	Weight 6%	Weight 40%	Strict Priority
1	Weight 6%	Weight 30%	Strict Priority
0	Weight 6%	Weight 30%	Strict Priority

Note that [Table 344](#) includes values for default, non-jumbo mode WRR. The hardware queues are calculated using default qosp values from [Table 340](#) on page 1976 as follows:

- Front end queue 3= 75% (qosp7) + 7% (qosp6) = 82%

- Front end queue 2 = 3% (qosp4) + 3% (qosp5) = 6%
- Front end queue 1 = 3% (qosp2) + 3% (qosp3) = 6%
- Front end queue 0 = 3% (qosp0) + 3% (qosp1) = 6%

The hardware queues for mixed WRR and SP mode are calculated as follows:

- Front end queue 3 is Strict Priority as default values for qosp7 and qosp6 are SP
- Front end queue 2 = 25% (qosp4) + 15% (qosp5) = 40%
- Front end queue 1 = 15% (qosp2) + 15% (qosp3) = 30%
- Front end queue 0 = 15% (qosp0) + 15% (qosp1) = 30%

Default scheduling configuration for the ICX 6430

The default scheduling configuration for Weighted Round Robin (WRR), Strict Priority (SP), and mixed WRR and SP mode for the eight QoS priority (qosp) queues mapped to the four hardware queues for an ICX 6430 is described in [Table 345](#).

TABLE 345 Default configuration for 8 to 4 queues (stand-alone system)

Hardware queue	Weighted Round Robin (WRR) mode	Mixed WRR and SP	Strict Priority (SP) mode
3	Weight 75%	Strict Priority	Strict Priority
2	Weight 10%	Strict Priority	Strict Priority
1	Weight 9%	Weight 70%	Strict Priority
0	Weight 6%	Weight 30%	Strict Priority

[Table 345](#) includes values for default, non-jumbo mode WRR for a stand-alone system. The hardware queues are calculated using default qosp values from [Table 341](#) on page 1977 as follows.

- Queue 3 = 75% (qosp7)
- Queue 2 = 3% (qosp5) + 7% (qosp6) = 10%
- Queue 1 = 3% (qosp2) + 3% (qosp3) + 3% (qosp4) = 9%
- Queue 0 = 3% (qosp0) + 3% (qosp1) = 6%

The hardware queues for mixed WRR and SP mode are calculated as follows:

- Queue 3 is Strict Priority as the default value for qosp7 is SP
- Queue 2 is Strict Priority as default values for qosp5 and qosp6 are SP
- Queue 1 = 15% (qosp2) + 15% (qosp3) + 40% (qosp4) = 70%
- Queue 0 = 15% (qosp0) + 15% (qosp1) = 30%

NOTE

If any qosp value is SP, then the weight of the hardware queue is SP.

Scheduling QoS information

Scheduling is the process of mapping a packet to an internal forwarding queue based on its QoS information, and servicing the queues according to a mechanism.

Scheduling for the SX-FI48GPP module

The SX-FI48GPP module supports scheduling at the front-end and back-end NP. If egress congestion occurs at the front-end NP of the SX-FI48GPP module, scheduling is based on four queues instead of eight. For more information on default configuration for 8 to 4 queue mapping, refer to [Table 334](#) on page 1972. If egress congestion occurs at the back-end of the SX-FI48GPP module, then scheduling is based on eight queues. When SX-FI48GPP ports are running at a reduced speed (100 Mbps or 10 Mbps), egress congestion usually occurs at the front-end NP.

QoS queuing methods

The following QoS queuing methods are supported in all IronWare releases for the FastIron devices:

- **Weighted Round Robin (WRR)** – WRR ensures that all queues are serviced during each cycle. A WRR algorithm is used to rotate service among the eight queues on the FastIron devices. The rotation is based on the weights you assign to each queue. This method rotates service among the queues, forwarding a specific number of packets in one queue before moving on to the next one.

NOTE

In stacking mode, the qosp7 queue is reserved as Strict Priority (SP) under weighted queuing. Attempts to change the qosp7 setting will be ignored.

WRR is the default queuing method and uses a default set of queue weights.

The number of packets serviced during each visit to a queue depends on the percentages you configure for the queues. The software automatically converts the percentages you specify into weights for the queues.

NOTE

Queue cycles on the FastIron devices are based on bytes. These devices service a given number of bytes (based on weight) in each queue cycle. FES and BI/FI queue cycles are based on packets. The bytes-based scheme is more accurate than a packets-based scheme if packets vary greatly in size.

- **Strict Priority (SP)** – SP ensures service for high-priority traffic. The software assigns the maximum weights to each queue, to cause the queuing mechanism to serve as many packets in one queue as possible before moving to a lower queue. This method biases the queuing mechanism to favor the higher queues over the lower queues.

For example, strict queuing processes as many packets as possible in qosp3 before processing any packets in qosp2, then processes as many packets as possible in qosp2 before processing any packets in qosp1, and so on.

- **Hybrid WRR and SP** – This configurable queueing mechanism combines both the SP and WRR mechanisms. The combined method enables the Brocade device to give strict priority to delay-sensitive traffic such as VoIP traffic, and weighted round robin priority to other traffic types.

By default, when you select the combined SP and WRR queueing method, the Brocade device assigns strict priority to traffic in qosp7 and qosp6, and weighted round robin priority to traffic in qosp0 through qosp5. Thus, the Brocade device schedules traffic in queue 7 and queue 6 first, based on the strict priority queueing method. When there is no traffic in queue 7 and queue 6, the device schedules the other queues in round-robin fashion from the highest priority queue to the lowest priority queue.

NOTE

Brocade stackable devices that are operating as members of a stack reserve queue 7 for stacking functions. For more information, refer to [“QoS for Brocade stackable devices”](#) on page 1970.

By default, when you specify the combined SP and WRR queueing method, the system balances the traffic among the queues as shown in [Table 346](#). If desired, you can change the default bandwidth values as shown in [“Bandwidth allocations of the hybrid WRR and SP queues”](#) on page 1991.

TABLE 346 Default bandwidth for combined SP and WRR queueing methods

Queue	Default bandwidth
qosp7	Strict Priority (highest priority)
qosp6	Strict Priority
qosp5	25%
qosp4	15%
qosp3	15%
qosp2	15%
qosp1	15%
qosp0	15% (lowest priority)

Selecting the QoS queueing method

By default, Brocade devices use the WRR method of packet prioritization. To change the method to SP, enter the **qos mechanism strict** command at the global CONFIG level of the CLI.

```
Brocade(config)#qos mechanism strict
```

To change the method back to WRR, enter the **qos mechanism weighted** command.

```
Brocade(config)#qos mechanism weighted
```

Syntax: [no] qos mechanism strict | weighted

To change the queueing mechanism to the combined SP and WRR method, enter the **qos mechanism mixed-sp-wrr** command at the global CONFIG level of the CLI.

```
Brocade(config)#qos mechanism mixed-sp-wrr
```

Syntax: qos mechanism mixed-sp-wrr

Configuring the QoS queues

Each of the queues has the following configurable parameters:

- The queue name
- The minimum percentage of a port outbound bandwidth guaranteed to the queue

Renaming the queues

The default queue names are qosp7, qosp6, qosp5, qosp4, qosp3, qosp2, qosp1, and qosp0. You can change one or more of the names if desired.

To rename queue “qosp3” to “92-octane”, enter the following command.

```
Brocade(config)#qos name qosp3 92-octane
```

Syntax: `qos name <old-name> <new-name>`

The `<old-name>` variable specifies the name of the queue before the change.

The `<new-name>` variable specifies the new name of the queue. You can specify an alphanumeric string up to 32 characters long.

Changing the minimum bandwidth percentages of the WRR queues

If you are using the weighted round robin mechanism instead of the strict priority mechanism, you can change the weights for each queue by changing the minimum percentage of bandwidth you want each queue to guarantee for its traffic.

NOTE

On the SX-FI48GPP interface module, the bandwidth percentages for 8 to 4 queue mapping for WRR queues are different from other Brocade SX modules. For more information on 8 to 4 queue mapping on the SX-FI48GPP interface module, refer to [“Default scheduling configuration for the SX-FI48GPP module”](#) on page 1985.

By default, the eight QoS queues on FastIron devices receive the minimum guaranteed percentages of a port’s total bandwidth, as shown in [Table 347](#). Note that the defaults differ when jumbo frames are enabled.

TABLE 347 Default minimum bandwidth percentages on Brocade devices

Queue	Default minimum percentage of bandwidth	
	Without jumbo frames	With jumbo frames
qosp7	75%	44%
qosp6	7%	8%
qosp5	3%	8%
qosp4	3%	8%
qosp3	3%	8%
qosp2	3%	8%
qosp1	3%	8%
qosp0	3%	8%

When the queuing method is WRR, the software internally translates the percentages into weights. The weight associated with each queue controls how many packets are processed for the queue at a given stage of a cycle through the weighted round robin algorithm.

NOTE

Queue cycles on the FastIron devices are based on bytes. These devices service a given number of bytes (based on the weight) in each queue cycle. FES and BI/FI queue cycles are based on packets. The bytes-based scheme is more accurate than a packets-based scheme if packets vary greatly in size.

The bandwidth allocated to each queue is based on the relative weights of the queues. You can change the bandwidth percentages allocated to the queues by changing the queue weights.

There is no minimum bandwidth requirement for a given queue. For example, queue qosp3 is not required to have at least 50 percent of the bandwidth.

To change the bandwidth percentages for the queues, enter commands such as the following. Note that this example uses the default queue names.

```
Brocade(config)#qos profile qosp7 25 qosp6 15 qosp5 12 qosp4 12 qosp3 10 qosp2
10 qosp1 10 qosp0 6
Profile qosp7      : Priority7    bandwidth requested 25% calculated 25%
Profile qosp6      : Priority6    bandwidth requested 15% calculated 15%
Profile qosp5      : Priority5    bandwidth requested 12% calculated 12%
Profile qosp4      : Priority4    bandwidth requested 12% calculated 12%
Profile qosp3      : Priority3    bandwidth requested 10% calculated 10%
Profile qosp2      : Priority2    bandwidth requested 10% calculated 10%
Profile qosp1      : Priority1    bandwidth requested 10% calculated 10%
Profile qosp0      : Priority0    bandwidth requested 6%  calculated 6%
```

Syntax: [no] qos profile <queue> <percentage> <queue> <percentage> <queue> <percentage>
 <queue> <percentage> <queue> <percentage> <queue> <percentage> <queue>
 <percentage> <queue> <percentage>

Each <queue> variable specifies the name of a queue. You can specify the queues in any order on the command line, but you must specify each queue.

The <percentage> variable specifies a number for the percentage of the device outbound bandwidth that is allocated to the queue. Brocade QoS queues require a minimum bandwidth percentage of 3 percent for each priority. When jumbo frames are enabled, the minimum bandwidth requirement is 8 percent. If these minimum values are not met, QoS may not be accurate.

Configuration notes for changing the bandwidth

- The total of the percentages you enter must equal 100.
- FastIron devices do not adjust the bandwidth percentages you enter. BigIron QoS does adjust the bandwidth percentages to ensure that each queue has at least its required minimum bandwidth percentage.

On FWS, FCX, and ICX devices, you can use QoS queue 1 for priority traffic, even when sFlow is enabled on the port. This differs from the FastIron X Series devices, which support seven priorities for user data instead of eight when sFlow is enabled. QoS queue 1 is reserved for sFlow and not used by other packets. Any non-sFlow packets assigned to QoS queue 1 will be directed to QoS queue 0. Note that the ICX 6430 does not support sFlow.

Bandwidth allocations of the hybrid WRR and SP queues

NOTE

On the SX-FI48GPP interface module, the bandwidth percentages for 8 to 4 queue mapping for hybrid WRR and SP queues are different from other Brocade SX modules. For more information on 8 to 4 queue mapping on the SX-FI48GPP interface module, refer to [“Default scheduling configuration for the SX-FI48GPP module”](#) on page 1985.

To change the default bandwidth percentages for the queues when the device is configured to use the combined SP and WRR queuing mechanism, enter commands such as the following. Note that this example uses the default queue names.

```
Brocade(config)#qos profile qosp7 sp qosp6 sp qosp5 20 qosp4 16 qosp3 16 qosp2 16
qosp1 16 qosp0 16
```

Syntax: [no] qos profile <queue 7> sp <queue 6> sp | <percentage> <queue 5> <percentage> <queue 4> <percentage> <queue 3> <percentage> <queue 2> <percentage> <queue 1> <percentage> <queue 0> <percentage>

Each <queue> specifies the name of a queue, such as 7, 6, 5, 4, 3, 2, 1, and 0. You can specify the queues in any order on the command line, but you must specify each queue. Note that queue 7 supports Strict Priority (sp) only, queue 6 supports both SP and WRR queuing mechanisms (sp |), and queues 0 through 5 support the WRR queuing mechanism only.

NOTE

Brocade stackable devices that are operating as members of a stack reserve queue 7 for stacking functions.

The **sp** parameter configures strict priority as the queuing mechanism. Note that only queue 7 and queue 6 support this method.

The <percentage> variable configures WRR as the queuing mechanism and specifies the percentage of the device outbound bandwidth allocated to the queue. The queues require a minimum bandwidth percentage of 3 percent for each priority. When jumbo frames are enabled, the minimum bandwidth requirement is 8 percent. If these minimum values are not met, QoS may not be accurate.

NOTE

The percentages must add up to 100. The Brocade FastIron devices do not adjust the bandwidth percentages you enter. In contrast, the BigIron QoS does adjust the bandwidth percentages to ensure that each queue has at least its required minimum bandwidth percentage.

Viewing QoS settings

To display the QoS settings for all of the queues, enter the **show qos-profiles** command.

The following example shows the output on an FESX device.

```
Brocade#show qos-profiles all
bandwidth scheduling mechanism: weighted priority
Profile qosp7      : Priority7   bandwidth requested 25% calculated 25%
Profile qosp6      : Priority6   bandwidth requested 15% calculated 15%
Profile qosp5      : Priority5   bandwidth requested 12% calculated 12%
Profile qosp4      : Priority4   bandwidth requested 12% calculated 12%
Profile qosp3      : Priority3   bandwidth requested 10% calculated 10%
Profile qosp2      : Priority2   bandwidth requested 10% calculated 10%
Profile qosp1      : Priority1   bandwidth requested 10% calculated 10%
Profile qosp0      : Priority0   bandwidth requested 6%  calculated 6%
```

Syntax: **show qos-profiles all** | **<name>**

The **all** parameter displays the settings for all eight queues.

The **<name>** variable displays the settings for the specified queue.

Viewing DSCP-based QoS settings

To display configuration information for DSCP-based QoS, enter the **show qos-tos** command at any level of the CLI.

```
Brocade#show qos-tos
DSCP-->Traffic-Class map: (DSCP = d1d2: 00, 01...63)
      d2|  0   1   2   3   4   5   6   7   8   9
d1  ----+-----
0   |  0   0   0   0   0   0   0   0   1   1
1   |  1   1   1   1   1   1   2   2   2   2
2   |  2   2   2   2   3   3   3   3   3   3
3   |  3   3   4   4   4   4   4   4   4   4
4   |  5   5   5   5   5   5   5   5   6   6
5   |  6   6   6   6   6   6   7   7   7   7
6   |  7   7   7   7   7   7   7   7   7   7

Traffic-Class-->802.1p-Priority map (use to derive DSCP--802.1p-Priority):
Traffic | 802.1p
Class   | Priority
-----+-----
0       | 0
1       | 1
2       | 2
3       | 3
4       | 4
5       | 5
6       | 6
7       | 7
-----+-----
```

Syntax: `show qos-tos`

[Table 348](#) shows the output information for the `show qos-tos` command.

TABLE 348 DSCP-based QoS configuration information

Field	Description
DSCP to traffic class map	
d1 and d2	The DSCP to forwarding priority mappings that are currently in effect. NOTE: The example shows the default mappings. If you change the mappings, the command displays the changed mappings
Traffic class to 802.1p priority map	
Traffic Class and 802.1p Priority	The traffic class to 802.1p priority mappings that are currently in effect. NOTE: The example shows the default mappings. If you change the mappings, the command displays the changed mappings.

The **show qos-tos** command can also be used to display configuration information for 8 to 4 queue mapping. The following example displays an 8 to 4 queue mapping configuration.

```
Brocade#show qos-tos
DSCP-->Traffic-Class map: (DSCP = d1d2: 00, 01...63)
```

d2	0	1	2	3	4	5	6	7	8	9
d1										
0	0	0	0	0	0	0	0	0	1	1
1	1	1	1	1	1	1	2	2	2	2
2	2	2	2	2	3	3	3	3	3	3
3	3	3	4	4	4	4	4	4	4	4
4	5	5	5	5	5	5	5	5	6	6
5	6	6	6	6	6	6	7	7	7	7
6	7	7	7	7						

```
Traffic-Class-->802.1p-Priority map (use to derive DSCP--802.1p-Priority):
```

Traffic Class	802.1p Priority
0	0
1	1
2	2
3	3
4	4
5	5
6	6
7	7

```
8to4 queue mapping:
```

Priority	Hardware Queue
0	0
1	0
2	1
3	1
4	2
5	2
6	3
7	3

[Table 349](#) shows the output information for 8 to 4 queue mapping for the **show qos-tos** command.

TABLE 349 8 to 4 queue mapping configuration information

Field	Description
8 to 4 queue mapping	
Priority and Hardware Queue	The priority to hardware queues that are currently in effect for 8 to 4 queue mapping on the SX-FI48GPP interface module. QoS priority 7 is the highest priority, and QoS 0 is the lowest priority

Syslog messages

[Table 1](#) lists all of the Syslog messages. Note that some of the messages apply only to Layer 3 switches.

NOTE

This chapter does not list Syslog messages that can be displayed when a debug option is enabled.

The messages are listed by message level, in the following order, then by message type:

- Emergencies (none)
- Alerts
- Critical
- Errors
- Warnings
- Notifications
- Informational
- Debugging

TABLE 1 Brocade Syslog messages

Message level	Message	Explanation
Alert	<num-modules> modules and 1 power supply, need more power supply!!	Indicates that the chassis needs more power supplies to run the modules in the chassis. The <num-modules> parameter indicates the number of modules in the chassis.
Alert	Fan <num>, <location>, failed	A fan has failed. The <num> is the fan number. The <location> describes where the failed fan is in the chassis.
Alert	MAC Authentication failed for <mac-address> on <portnum>	RADIUS authentication was successful for the specified <mac-address> on the specified <portnum>; however, the VLAN returned in the RADIUS Access-Accept message did not refer to a valid VLAN or VLAN ID on the Brocade device. This is treated as an authentication failure.
Alert	MAC Authentication failed for <mac-address> on <portnum> (Invalid User)	RADIUS authentication failed for the specified <mac-address> on the specified <portnum> because the MAC address sent to the RADIUS server was not found in the RADIUS server users database.

TABLE 1 Brocade Syslog messages (Continued)

Message level	Message	Explanation
Alert	MAC Authentication failed for <mac-address> on <portnum> (No VLAN Info received from RADIUS server)	RADIUS authentication was successful for the specified <mac-address> on the specified <portnum>; however, dynamic VLAN assignment was enabled for the port, but the RADIUS Access-Accept message did not include VLAN information. This is treated as an authentication failure.
Alert	MAC Authentication failed for <mac-address> on <portnum> (Port is already in another radius given vlan)	RADIUS authentication was successful for the specified <mac-address> on the specified <portnum>; however, the RADIUS Access-Accept message specified a VLAN ID, although the port had previously been moved to a different RADIUS-assigned VLAN. This is treated as an authentication failure.
Alert	MAC Authentication failed for <mac-address> on <portnum> (RADIUS given vlan does not exist)	RADIUS authentication was successful for the specified <mac-address> on the specified <portnum>; however, the RADIUS Access-Accept message specified a VLAN that does not exist in the Brocade configuration. This is treated as an authentication failure.
Alert	MAC Authentication failed for <mac-address> on <portnum> (RADIUS given VLAN does not match with TAGGED vlan)	Multi-device port authentication failed for the <mac-address> on a tagged port because the packet with this MAC address as the source was tagged with a VLAN ID different from the RADIUS-supplied VLAN ID.
Alert	Management module at slot <slot-num> state changed from <module-state> to <module-state>.	Indicates a state change in a management module. The <slot-num> indicates the chassis slot containing the module. The <module-state> can be one of the following: <ul style="list-style-type: none"> • active • standby • crashed • coming-up • unknown
Alert	OSPF LSA Overflow, LSA Type = <lsa-type>	Indicates an LSA database overflow. The <lsa-type> parameter indicates the type of LSA that experienced the overflow condition. The LSA type is one of the following: <ul style="list-style-type: none"> • 1 – Router • 2 – Network • 3 – Summary • 4 – Summary • 5 – External
Alert	OSPF Memory Overflow	OSPF has run out of memory.

TABLE 1 Brocade Syslog messages (Continued)

Message level	Message	Explanation
Alert	Power supply <num>, <location>, failed	A power supply has failed. The <num> is the power supply number. The <location> describes where the failed power supply is in the chassis.
Alert	System: Module in slot <slot-num> encountered PCI config read error: Bus <PCI-bus-number>, Dev <PCI-device-number>, Reg Offset <PCI-config-register-offset>.	The module encountered a hardware configuration read error.
Alert	System: Module in slot <slot-num> encountered PCI config write error: Bus <PCI-bus-number>, Dev <PCI-device-number>, Reg Offset <PCI-config-register-offset>.	The module encountered a hardware configuration write error.
Alert	System: Module in slot <slot-num> encountered PCI memory read error: Mem Addr <memory-address>	The module encountered a hardware memory read error. The <memory-address> is in hexadecimal format.
Alert	System: Module in slot <slot-num> encountered PCI memory write error: Mem Addr <memory-address>.	The module encountered a hardware memory write error. The <memory-address> is in hexadecimal format.
Alert	System: Module in slot <slot-num> encountered unrecoverable PCI bridge validation failure. Module will be deleted.	The module encountered an unrecoverable (hardware) bridge validation failure. The module will be disabled or powered down.
Alert	System: Module in slot <slot-num> encountered unrecoverable PCI config read failure. Module will be deleted.	The module encountered an unrecoverable hardware configuration read failure. The module will be disabled or powered down.
Alert	System: Module in slot <slot-num> encountered unrecoverable PCI config write failure. Module will be deleted.	The module encountered an unrecoverable hardware configuration write failure. The module will be disabled or powered down.
Alert	System: Module in slot <slot-num> encountered unrecoverable PCI device validation failure. Module will be deleted.	The module encountered an unrecoverable (hardware) device validation failure. The module will be disabled or powered down.
Alert	System: Module in slot <slot-num> encountered unrecoverable PCI memory read failure. Module will be deleted.	The module encountered an unrecoverable hardware memory read failure. The module will be disabled or powered down.
Alert	System: Module in slot <slot-num> encountered unrecoverable PCI memory write failure. Module will be deleted.	The module encountered an unrecoverable hardware memory write failure. The module will be disabled or powered down.
Alert	System: No Free Tcam Entry available. System will be unstable	In FWS devices, the limit for the TCAM routing entries has been reached. You must reboot the device.
Alert	System: Temperature is over shutdown level, system is going to be reset in <num> seconds	The chassis temperature has risen above shutdown level. The system will be shut down in the amount of time indicated.

TABLE 1 Brocade Syslog messages (Continued)

Message level	Message	Explanation
Alert	Temperature <degrees> C degrees, warning level <warn-degrees> C degrees, shutdown level <shutdown-degrees> C degrees	Indicates an over temperature condition on the active module. The <degrees> value indicates the temperature of the module. The <warn-degrees> value is the warning threshold temperature configured for the module. The <shutdown-degrees> value is the shutdown temperature configured for the module.
Critical	Authentication shut down <portnum> due to DOS attack	Denial of Service (DoS) attack protection was enabled for multi-device port authentication on the specified <portnum>, and the per-second rate of RADIUS authentication attempts for the port exceeded the configured limit. The Brocade device considers this to be a DoS attack and disables the port.
Debug	BGP4: Not enough memory available to run BGP4	The device could not start the BGP4 routing protocol because there is not enough memory available.
Debug	DOT1X: Not enough memory	There is not enough system memory for 802.1X authentication to take place. Contact Brocade Technical Support.
Error	No of prefixes received from BGP peer <ip-addr> exceeds maximum prefix-limit...shutdown	The Layer 3 switch has received more than the specified maximum number of prefixes from the neighbor, and the Layer 3 switch is therefore shutting down its BGP4 session with the neighbor.
Informational	IPv6: IPv6 protocol disabled on the device from <session-id>	IPv6 protocol was disabled on the device during the specified session.
Informational	IPv6: IPv6 protocol enabled on the device from <session-id>	IPv6 protocol was enabled on the device during the specified session.
Informational	MAC Filter applied to port <port-id> by <username> from <session-id> (filter id=<filter-ids>)	Indicates a MAC address filter was applied to the specified port by the specified user during the specified session. <session-id> can be console, telnet, ssh, web, or snmp. <filter-ids> is a list of the MAC address filters that were applied.
Informational	MAC Filter removed from port <port-id> by <username> from <session-id> (filter id=<filter-ids>)	Indicates a MAC address filter was removed from the specified port by the specified user during the specified session. <session-id> can be console, telnet, ssh, web, or snmp. <filter-ids> is a list of the MAC address filters that were removed.

TABLE 1 Brocade Syslog messages (Continued)

Message level	Message	Explanation
Informational	Security: Password has been changed for user <username> from <session-id>	Password of the specified user has been changed during the specified session ID or type. <session-id> can be console, telnet, ssh, web, or snmp.
Informational	<device-name> : Logical link on interface ethernet <slot#/port#> is down.	The specified ports were logically brought down while singleton was configured on the port.
Informational	<device-name>: Logical link on interface ethernet <slot#/port#> is up.	The specified ports were logically brought up while singleton was configured on the port.
Informational	<user-name> login to PRIVILEGED mode	A user has logged into the Privileged EXEC mode of the CLI. The <user-name> is the user name.
Informational	<user-name> login to USER EXEC mode	A user has logged into the USER EXEC mode of the CLI. The <user-name> is the user name.
Informational	<user-name> logout from PRIVILEGED mode	A user has logged out of Privileged EXEC mode of the CLI. The <user-name> is the user name.
Informational	<user-name> logout from USER EXEC mode	A user has logged out of the USER EXEC mode of the CLI. The <user-name> is the user name.
Informational	ACL <ACL id> added deleted modified from console telnet ssh web snmp session	A user created, modified, deleted, or applied an ACL through a Web, SNMP, console, SSH, or Telnet session.
Informational	Bridge is new root, vlan <vlan-id>, root ID <root-id>	A Spanning Tree Protocol (STP) topology change has occurred, resulting in the Brocade device becoming the root bridge. The <vlan-id> is the ID of the VLAN in which the STP topology change occurred. The <root-id> is the STP bridge root ID.
Informational	Bridge root changed, vlan <vlan-id>, new root ID <string>, root interface <portnum>	A Spanning Tree Protocol (STP) topology change has occurred. The <vlan-id> is the ID of the VLAN in which the STP topology change occurred. The <root-id> is the STP bridge root ID. The <portnum> is the number of the port connected to the new root bridge.

TABLE 1 Brocade Syslog messages (Continued)

Message level	Message	Explanation
Informational	Bridge topology change, vlan <vlan-id>, interface <portnum>, changed state to <stp-state>	<p>A Spanning Tree Protocol (STP) topology change has occurred on a port.</p> <p>The <vlan-id> is the ID of the VLAN in which the STP topology change occurred.</p> <p>The <portnum> is the port number.</p> <p>The <stp-state> is the new STP state and can be one of the following:</p> <ul style="list-style-type: none"> • disabled • blocking • listening • learning • forwarding • unknown
Informational	Cold start	The device has been powered on.
Informational	DHCP : snooping on untrusted port <portnum>, type <number>, drop	The device has indicated that the DHCP client receives DHCP server reply packets on untrusted ports, and packets are dropped.
Informational	DOT1X : port <portnum> - mac <mac address> Cannot apply an ACL or MAC filter on a port member of a VE (virtual interface)	The RADIUS server returned an IP ACL or MAC address filter, but the port is a member of a virtual interface (VE).
Informational	DOT1X : port <portnum> - mac <mac address> cannot remove inbound ACL	An error occurred while removing the inbound ACL.
Informational	DOT1X : port <portnum> - mac <mac address> Downloading a MAC filter, but MAC filter have no effect on router port	The RADIUS server returned an MAC address filter, but the <portnum> is a router port (it has one or more IP addresses).
Informational	DOT1X : port <portnum> - mac <mac address> Downloading an IP ACL, but IP ACL have no effect on a switch port	The RADIUS server returned an IP ACL, but the <portnum> is a switch port (no IP address).
Informational	DOT1X : port <portnum> - mac <mac address> Error - could not add all MAC filters	The Brocade device was unable to implement the MAC address filters returned by the RADIUS server.
Informational	DOT1X : port <portnum> - mac <mac address> Invalid MAC filter ID - this ID doesn't exist	The MAC address filter ID returned by the RADIUS server does not exist in the Brocade configuration.
Informational	DOT1X : port <portnum> - mac <mac address> Invalid MAC filter ID - this ID is user defined and cannot be used	The port was assigned a MAC address filter ID that had been dynamically created by another user.
Informational	DOT1X : port <portnum> - mac <mac address> is unauthorized because system resource is not enough or the invalid information to set the dynamic assigned IP ACLs or MAC address filters	802.1X authentication failed for the Client with the specified <mac address> on the specified <portnum> either due to insufficient system resources on the device, or due to invalid IP ACL or MAC address filter information returned by the RADIUS server.
Informational	DOT1X : port <portnum> - mac <mac address> Port is already bound with MAC filter	The RADIUS server returned a MAC address filter, but a MAC address filter had already been applied to the port.

TABLE 1 Brocade Syslog messages (Continued)

Message level	Message	Explanation
Informational	DOT1X : port <portnum> - mac <mac address> This device doesn't support ACL with MAC Filtering on the same port	The RADIUS server returned a MAC address filter while an IP ACL was applied to the port, or returned an IP ACL while a MAC address filter was applied to the port.
Informational	DOT1X Port <portnum> is unauthorized because system resource is not enough or the invalid information to set the dynamic assigned IP ACLs or MAC address filters	802.1X authentication could not take place on the port. This happened because strict security mode was enabled and one of the following occurred: <ul style="list-style-type: none"> Insufficient system resources were available on the device to apply an IP ACL or MAC address filter to the port Invalid information was received from the RADIUS server (for example, the Filter-ID attribute did not refer to an existing IP ACL or MAC address filter)
Informational	DOT1X: Port <portnum> currently used vlan-id changes to <vlan-id> due to dot1x-RADIUS vlan assignment	A user has completed 802.1X authentication. The profile received from the RADIUS server specifies a VLAN ID for the user. The port to which the user is connected has been moved to the VLAN indicated by <vlan-id>.
Informational	DOT1X: Port <portnum> currently used vlan-id is set back to port default vlan-id <vlan-id>	The user connected to <portnum> has disconnected, causing the port to be moved back into its default VLAN, <vlan-id>.
Informational	DOT1X: Port <portnum>, AuthControlledPortStatus change: authorized	The status of the interface controlled port has changed from unauthorized to authorized.
Informational	DOT1X: Port <portnum>, AuthControlledPortStatus change: unauthorized	The status of the interface controlled port has changed from authorized to unauthorized.
Informational	Enable super port-config read-only password deleted added modified from console telnet ssh web snmp OR Line password deleted added modified from console telnet ssh web snmp	A user created, re-configured, or deleted an Enable or Line password through the Web, SNMP, console, SSH, or Telnet session.
Informational	ERR_DISABLE: Interface ethernet <port-number>, err-disable recovery timeout	Errdisable recovery timer expired and the port has been reenabled.
Informational	ERR_DISABLE: Interface ethernet 16, err-disable recovery timeout	If the wait time (port is down and is waiting to come up) expires and the port is brought up the following message is displayed.
Informational	ERR_DISABLE: Link flaps on port ethernet 16 exceeded threshold; port in err-disable state	The threshold for the number of times that a port link toggles from "up" to "down" and "down" to "up" has been exceeded.
Informational	Interface <portnum>, line protocol down	The line protocol on a port has gone down. The <portnum> is the port number.
Informational	Interface <portnum>, line protocol up	The line protocol on a port has come up. The <portnum> is the port number.

TABLE 1 Brocade Syslog messages (Continued)

Message level	Message	Explanation
Informational	Interface <portnum>, state down	A port has gone down. The <portnum> is the port number.
Informational	Interface <portnum>, state up	A port has come up. The <portnum> is the port number.
Informational	MAC Based Vlan Disabled on port <port id>	A MAC Based VLAN has been disabled on a port
Informational	MAC Based Vlan Enabled on port <port id>	A MAC Based VLAN has been enabled on a port.
Informational	MAC Filter added deleted modified from console telnet ssh web snmp session filter id = <MAC filter ID>, src mac = <Source MAC address> any, dst mac = <Destination MAC address> any	A user created, modified, deleted, or applied this MAC address filter through the Web, SNMP, console, SSH, or Telnet session.
Informational	MSTP: BPDU-guard interface ethernet <port-number> detect (Received BPDU), putting into err-disable state.	BPDU guard violation occurred in MSTP.
Informational	OPTICAL MONITORING: port <port-number> is not capable.	The optical transceiver is qualified by Brocade, but the transceiver does not support digital optical performance monitoring.
Informational	Port <p> priority changed to <n>	A port priority has changed.
Informational	Port <portnum>, srcip-security max-ipaddr-per-int reached.Last IP=<ipaddr>	The address limit specified by the srcip-security max-ipaddr-per-interface command has been reached for the port.
Informational	Port <portnum>, srcip-security max-ipaddr-per-int reached.Last IP=<ipaddr>	The address limit specified by the srcip-security max-ipaddr-per-interface command has been reached for the port.
Informational	Security: console login by <username> to USER PRIVILEGE EXEC mode	The specified user logged into the device console into the specified EXEC mode.
Informational	Security: console logout by <username>	The specified user logged out of the device console.
Informational	Security: telnet SSH login by <username> from src IP <ip-address>, src MAC <mac-address> to USER PRIVILEGE EXEC mode	The specified user logged into the device using Telnet or SSH from either or both the specified IP address and MAC address. The user logged into the specified EXEC mode.
Informational	Security: telnet SSH logout by <username> from src IP <ip-address>, src MAC <mac-address> to USER PRIVILEGE EXEC mode	The specified user logged out of the device. The user was using Telnet or SSH to access the device from either or both the specified IP address and MAC address. The user logged out of the specified EXEC mode.
Informational	SNMP read-only community read-write community contact location user group view engineld trap [host] [<value-str>] deleted added modified from console telnet ssh web snmp session	A user made SNMP configuration changes through the Web, SNMP, console, SSH, or Telnet session. [<value-str>] does not appear in the message if SNMP community or engineld is specified.

TABLE 1 Brocade Syslog messages (Continued)

Message level	Message	Explanation
Informational	SNMP Auth. failure, intruder IP: <ip-addr>	A user has tried to open a management session with the device using an invalid SNMP community string. The <ip-addr> is the IP address of the host that sent the invalid community string.
Informational	SSH telnet server enabled disabled from console telnet ssh web snmp session [by user <username>]	A user enabled or disabled an SSH or Telnet session, or changed the SSH enable/disable configuration through the Web, SNMP, console, SSH, or Telnet session.
Informational	startup-config was changed or startup-config was changed by <user-name>	A configuration change was saved to the startup-config file. The <user-name> is the user ID, if they entered a user ID to log in.
Informational	STP: Root Guard Port <port-number>, VLAN <vlan-ID> consistent (Timeout).	Root guard unblocks a port.
Informational	STP: Root Guard Port <port-number>, VLAN <vlan-ID> inconsistent (Received superior BPDU).	Root guard blocked a port.
Informational	STP: VLAN <vlan id> BPDU-Guard on Port <port id> triggered (Received BPDU), putting into err-disable state	The BPDU guard feature has detected an incoming BPDU on {vlan-id, port-id}
Informational	STP: VLAN <vlan id> Root-Protect Port <port id>, Consistent (Timeout)	The root protect feature goes back to the consistent state.
Informational	STP: VLAN <vlan id> Root-Protect Port <port id>, Inconsistent (Received superior BPDU)	The root protect feature has detected a superior BPDU and goes into the inconsistent state on {vlan-id, port-id}.
Informational	STP: VLAN <vlan-id> BPDU-guard port <port-number> detect (Received BPDU), putting into err-disable state	STP placed a port into an errdisable state for BPDU guard.
Informational	STP: VLAN 1 BPDU-guard port <port-number> detect (Received BPDU), putting into err-disable state.	BPDU guard violation in occurred in STP or RSTP.
Informational	Syslog server <IP-address> deleted added modified from console telnet ssh web snmp OR Syslog operation enabled disabled from console telnet ssh web snmp	A user made Syslog configuration changes to the specified Syslog server address, or enabled or disabled a Syslog operation through the Web, SNMP, console, SSH, or Telnet session.
Informational	SYSTEM: Optic is not Brocade-qualified (<port-number>)	Brocade does not support the optical transceiver.
Informational	System: Fan <fan id> (from left when facing right side), ok	The fan status has changed from fail to normal.
Informational	System: Fan speed changed automatically to <fan speed>	The system automatically changed the fan speed to the speed specified in this message.
Informational	System: No free TCAM entry. System will be unstable	There are no TCAM entries available.

TABLE 1 Brocade Syslog messages (Continued)

Message level	Message	Explanation
Informational	System: Static Mac entry with Mac Address <mac-address> is added from the <unit>/<slot>/<port> to <unit>/<slot>/<port> on VLANs <vlan-id> to <vlan-id>	A MAC address is added to a range of interfaces, which are members of the specified VLAN range.
Informational	System: Static Mac entry with Mac Address <mac-address> is added to ethe <unit>/<slot>/<port> to <unit>/<slot>/<port> on <vlan-id>	A MAC address is added to a range of interfaces, which are members of the specified VLAN.
Informational	System: Static Mac entry with Mac Address <mac-address> is added to portnumber <unit>/<slot>/<port> on VLAN <vlan-id>	A MAC address is added to an interface and the interface is a member of the specified VLAN.
Informational	System: Static Mac entry with Mac Address <mac-address> is deleted from ethe <unit>/<slot>/<port> to <unit>/<slot>/<port> on <vlan-id>	A MAC address is deleted from a range of interfaces, which are members of the specified VLAN.
Informational	System: Static Mac entry with Mac Address <mac-address> is deleted from ethe <unit>/<slot>/<port> to <unit>/<slot>/<port> on VLANs <vlan-id> to <vlan-id>	A MAC address is deleted from a range of interfaces, which are members of the specified VLAN range.
Informational	System: Static Mac entry with Mac Address <mac-address> is deleted from portnumber <unit>/<slot>/<port> on <vlan-id>	A MAC address is deleted from an interface and the interface is a member of the specified VLAN.
Informational	System: Static Mac entry with Mac Address <mac-address> is deleted from portnumber <unit>/<slot>/<port> on VLANs <vlan-id> to <vlan-id>	A MAC address is deleted from an interface and the interface is a member of the specified VLAN range.
Informational	telnet SSH web access [by <username>] from src IP <source ip address>, src MAC <source MAC address> rejected, <n> attempts	There were failed web, SSH, or Telnet login access attempts from the specified source IP and MAC address. <ul style="list-style-type: none"> [by <user> <username>] does not appear if telnet or SSH clients are specified. <n> is the number of times this SNMP trap occurred in the last five minutes, or other configured number of minutes.
Informational	Trunk group (<ports>) created by 802.3ad link-aggregation module.	802.3ad link aggregation is configured on the device, and the feature has dynamically created a trunk group (aggregate link). The <ports> is a list of the ports that were aggregated to make the trunk group.
Informational	user <username> added deleted modified from console telnet ssh web snmp	A user created, modified, or deleted a local user account through the Web, SNMP, console, SSH, or Telnet session.
Informational	vlan <vlan id> added deleted modified from console telnet ssh web snmp session	A user created, modified, or deleted a VLAN through the Web, SNMP, console, SSH, or Telnet session.

TABLE 1 Brocade Syslog messages (Continued)

Message level	Message	Explanation
Informational	Warm start	The system software (flash code) has been reloaded.
Informational	Stack: Stack unit <unit#> has been deleted to the stack system	The specified unit has been deleted from the stacking system.
Informational	Stack unit <unitNumber> has been elected as ACTIVE unit of the stack system	The specified unit in a stack has been elected as the Master unit for the stacking system.
Informational	Stack: Stack unit <unit#> has been added to the stack system	The specified unit has been added to the stacking system.
Informational	System: Management MAC address changed to <mac_address>	The management MAC address of a stacking system has been changed
Informational	System: Stack unit <unit#> Fan <fan#> (<description>), failed	The operational status of a fan in the specified unit in a stack changed from normal to failure.
Informational	System: Stack unit <unit#> Power supply <power-supply#> is down	The operational status of a power supply of the specified unit in a stack changed from normal to failure.
Informational	System: Stack unit <unit#> Power supply <power-supply#> is up	The operational status of a power supply of the specified unit in a stack changed from failure to normal.
Informational	System: Stack unit <unit#> Fan <fan#> (<description>), ok	The operational status of a fan in the specified unit in a stack changed from failure to normal.
Informational	System: Stack unit <unitNumber> Temperature <actual-temp> C degrees, warning level <warning-temp> C degrees, shutdown level <shutdown-temp> C degrees	The actual temperature reading for a unit in a stack is above the warning temperature threshold.
Informational	vlan <vlan-id> Bridge is RootBridge <mac-address> (MgmtPriChg)	802.1W changed the current bridge to be the root bridge of the given topology due to administrative change in bridge priority.
Informational	vlan <vlan-id> Bridge is RootBridge <mac-address> (MsgAgeExpiry)	The message age expired on the Root port so 802.1W changed the current bridge to be the root bridge of the topology.
Informational	vlan <vlan-id> interface <portnum> Bridge TC Event (DOT1wTransition)	802.1W recognized a topology change event in the bridge. The topology change event is the forwarding action that started on a non-edge Designated port or Root port.
Informational	vlan <vlan-id> interface <portnum> STP state -> <state> (DOT1wTransition)	802.1W changed the state of a port to a new state: forwarding, learning, blocking. If the port changes to blocking, the bridge port is in discarding state.
Informational	vlan <vlan-id> New RootBridge <mac-address> RootPort <portnum> (BpduRcvd)	802.1W selected a new root bridge as a result of the BPDUs received on a bridge port.
Informational	vlan <vlan-id> New RootPort <portnum> (RootSelection)	802.1W changed the port role to Root port, using the root selection computation.

TABLE 1 Brocade Syslog messages (Continued)

Message level	Message	Explanation
Notification	ACL exceed max DMA L4 cam resource, using flow based ACL instead	The port does not have enough Layer 4 CAM entries for the ACL. To correct this condition, allocate more Layer 4 CAM entries. To allocate more Layer 4 CAM entries, enter the following command at the CLI configuration level for the interface: ip access-group max-l4-cam <num>
Notification	ACL insufficient L4 cam resource, using flow based ACL instead	The port does not have a large enough CAM partition for the ACLs
Notification	ACL insufficient L4 session resource, using flow based ACL instead	The device does not have enough Layer 4 session entries. To correct this condition, allocate more memory for sessions. To allocate more memory, enter the following command at the global CONFIG level of the CLI interface: system-max session-limit <num>
Notification	ACL port fragment packet inspect rate <rate> exceeded on port <portnum>	The fragment rate allowed on an individual interface has been exceeded. The <rate> indicates the maximum rate allowed. The <portnum> indicates the port. This message can occur if fragment throttling is enabled.
Notification	ACL system fragment packet inspect rate <rate> exceeded	The fragment rate allowed on the device has been exceeded. The <rate> indicates the maximum rate allowed. This message can occur if fragment throttling is enabled.
Notification	Authentication Disabled on <portnum>	The multi-device port authentication feature was disabled on the on the specified <portnum>.
Notification	Authentication Enabled on <portnum>	The multi-device port authentication feature was enabled on the on the specified <portnum>.
Notification	BGP Peer <ip-addr> DOWN (IDLE)	Indicates that a BGP4 neighbor has gone down. The <ip-addr> is the IP address of the neighbor BGP4 interface with the Brocade device.
Notification	BGP Peer <ip-addr> UP (ESTABLISHED)	Indicates that a BGP4 neighbor has come up. The <ip-addr> is the IP address of the neighbor BGP4 interface with the Brocade device.
Notification	DHCP : snooping on untrusted port <portnum>, type <number>, drop	Indicates that the DHCP client receives DHCP server reply packets on untrusted ports, and packets are dropped.

TABLE 1 Brocade Syslog messages (Continued)

Message level	Message	Explanation
Notification	DOT1X issues software but not physical port down indication of Port <portnum> to other software applications	The device has indicated that the specified is no longer authorized, but the actual port may still be active.
Notification	DOT1X issues software but not physical port up indication of Port <portnum> to other software applications	The device has indicated that the specified port has been authenticated, but the actual port may not be active.
Notification	DOT1X: Port <port_id> Mac <mac_address> -user <user_id> - RADIUS timeout for authentication	The RADIUS session has timed out for this 802.1x port.
Notification	ISIS L1 ADJACENCY DOWN <system-id> on circuit <circuit-id>	The Layer 3 switch adjacency with this Level-1 IS has gone down. The <system-id> is the system ID of the IS. The <circuit-id> is the ID of the circuit over which the adjacency was established.
Notification	ISIS L1 ADJACENCY UP <system-id> on circuit <circuit-id>	The Layer 3 switch adjacency with this Level-1 IS has come up. The <system-id> is the system ID of the IS. The <circuit-id> is the ID of the circuit over which the adjacency was established.
Notification	ISIS L2 ADJACENCY DOWN <system-id> on circuit <circuit-id>	The Layer 3 switch adjacency with this Level-2 IS has gone down. The <system-id> is the system ID of the IS. The <circuit-id> is the ID of the circuit over which the adjacency was established.
Notification	ISIS L2 ADJACENCY UP <system-id> on circuit <circuit-id>	The Layer 3 switch adjacency with this Level-2 IS has come up. The <system-id> is the system ID of the IS. The <circuit-id> is the ID of the circuit over which the adjacency was established.
Notification	Local ICMP exceeds <burst-max> burst packets, stopping for <lockup> seconds!!	The number of ICMP packets exceeds the <burst-max> threshold set by the ip icmp burst command. The Brocade device may be the victim of a Denial of Service (DoS) attack. All ICMP packets will be dropped for the number of seconds specified by the <lockup> value. When the lockup period expires, the packet counter is reset and measurement is restarted.
Notification	Local TCP exceeds <burst-max> burst packets, stopping for <lockup> seconds!!	The number of TCP SYN packets exceeds the <burst-max> threshold set by the ip tcp burst command. The Brocade device may be the victim of a TCP SYN DoS attack. All TCP SYN packets will be dropped for the number of seconds specified by the <lockup> value. When the lockup period expires, the packet counter is reset and measurement is restarted.

TABLE 1 Brocade Syslog messages (Continued)

Message level	Message	Explanation
Notification	Local TCP exceeds <num> burst packets, stopping for <num> seconds!!	<p>Threshold parameters for local TCP traffic on the device have been configured, and the maximum burst size for TCP packets has been exceeded.</p> <p>The first <num> is the maximum burst size (maximum number of packets allowed). The second <num> is the number of seconds during which additional TCP packets will be blocked on the device.</p> <p>NOTE: This message can occur in response to an attempted TCP SYN attack.</p>
Notification	MAC Authentication RADIUS timeout for <mac_address> on port <port_id>	The RADIUS session has timed out for the MAC address for this port.
Notification	MAC Authentication succeeded for <mac-address> on <portnum>	RADIUS authentication was successful for the specified <mac-address> on the specified <portnum>.

TABLE 1 Brocade Syslog messages (Continued)

Message level	Message	Explanation
Notification	VRRP intf state changed, intf <portnum>, vrid <virtual-router-id>, state <vrrp-state> VRRP (IPv6) intf state changed, intf <portnum>, vrid <virtual-router-id>, state <vrrp-state>	A state change has occurred in a Virtual Router Redundancy Protocol (VRRP) or VRRP-E IPv4 or IPv6 interface. The <portnum> is the port or interface where VRRP or VRRP-E is configured. The <virtual-router-id> is the virtual router ID (VRID) configured on the interface. The <vrrp-state> can be one of the following: <ul style="list-style-type: none"> • init • master • backup • unknown
Warning	DOT1X security violation at port <portnum>, malicious mac address detected: <mac-address>	A security violation was encountered at the specified port number.
Warning	Dup IP <ip-addr> detected, sent from MAC <mac-addr> interface <portnum>	Indicates that the Brocade device received a packet from another device on the network with an IP address that is also configured on the Brocade device. The <ip-addr> is the duplicate IP address. The <mac-addr> is the MAC address of the device with the duplicate IP address. The <portnum> is the Brocade port that received the packet with the duplicate IP address. The address is the packet source IP address.
Warning	IGMP/MLD no hardware vidx, broadcast to the entire vlan. rated limited number	IGMP or MLD snooping has run out of hardware application VLANs. There are 4096 application VLANs per device. Traffic streams for snooping entries without an application VLAN are switched to the entire VLAN and to the CPU to be dropped. This message is rate-limited to appear a maximum of once every 10 minutes. The rate-limited number shows the number on non-printed warnings.
Warning	IGMP/MLD: <vlanId>(<portId>) is V1 but rcvd V2 from nbr <ipAddr>	Port has received a query with a MLD version that does not match the port MLD version. This message is rated-limited to appear a maximum of once every 10 hours.
Warning	Latched low RX Power TX Power TX Bias Current Supply Voltage Temperature warning alarm warning, port <port-number>	The optical transceiver on the given port has risen above or fallen below the alarm or warning threshold.

TABLE 1 Brocade Syslog messages (Continued)

Message level	Message	Explanation
Warning	list <ACL-num> denied <ip-proto> <src-ip-addr> (<src-tcp/udp-port>) (Ethernet <portnum> <mac-addr>) -> <dst-ip-addr> (<dst-tcp/udp-port>), 1 event(s)	<p>Indicates that an Access Control List (ACL) denied (dropped) packets.</p> <p>The <ACL-num> indicates the ACL number. Numbers 1 – 99 indicate standard ACLs. Numbers 100 – 199 indicate extended ACLs.</p> <p>The <ip-proto> indicates the IP protocol of the denied packets.</p> <p>The <src-ip-addr> is the source IP address of the denied packets.</p> <p>The <src-tcp/udp-port> is the source TCP or UDP port, if applicable, of the denied packets.</p> <p>The <portnum> indicates the port number on which the packet was denied.</p> <p>The <mac-addr> indicates the source MAC address of the denied packets.</p> <p>The <dst-ip-addr> indicates the destination IP address of the denied packets.</p> <p>The <dst-tcp/udp-port> indicates the destination TCP or UDP port number, if applicable, of the denied packets.</p>
Warning	Locked address violation at interface e<portnum>, address <mac-address>	<p>Indicates that a port on which you have configured a lock-address filter received a packet that was dropped because the packet source MAC address did not match an address learned by the port before the lock took effect.</p> <p>The e<portnum> is the port number.</p> <p>The <mac-address> is the MAC address that was denied by the address lock.</p> <p>Assuming that you configured the port to learn only the addresses that have valid access to the port, this message indicates a security violation.</p>
Warning	mac filter group denied packets on port <portnum> src macaddr <mac-addr>, <num> packets	<p>Indicates that a MAC address filtergroup configured on a port has denied packets.</p> <p>The <portnum> is the port on which the packets were denied.</p> <p>The <mac-addr> is the source MAC address of the denied packets.</p> <p>The <num> indicates how many packets matching the values above were dropped during the five-minute interval represented by the log entry.</p>
Warning	multicast no software resource: resource-name, rate limited number	<p>IGMP or MLD snooping has run out of software resources. This message is rate-limited to appear a maximum of once every 10 minutes. The rate-limited number shows the number of non-printed warnings.</p>

TABLE 1 Brocade Syslog messages (Continued)

Message level	Message	Explanation
Warning	No global IP! cannot send IGMP msg.	The device is configured for ip multicast active but there is no configured IP address and the device cannot send out IGMP queries.
Warning	No of prefixes received from BGP peer <ip-addr> exceeds warning limit <num>	<p>The Layer 3 switch has received more than the allowed percentage of prefixes from the neighbor.</p> <p>The <ip-addr> is the IP address of the neighbor.</p> <p>The <num> is the number of prefixes that matches the percentage you specified. For example, if you specified a threshold of 100 prefixes and 75 percent as the warning threshold, this message is generated if the Layer 3 switch receives a 76th prefix from the neighbor.</p>
Warning	NTP server <ip-addr> failed to respond	<p>Indicates that a Simple Network Time Protocol (SNTP) server did not respond to the device query for the current time.</p> <p>The <ip-addr> indicates the IP address of the SNTP server.</p>
Warning	rip filter list <list-num> <direction> V1 V2 denied <ip-addr>, <num> packets	<p>Indicates that a RIP route filter denied (dropped) packets.</p> <p>The <list-num> is the ID of the filter list.</p> <p>The <direction> indicates whether the filter was applied to incoming packets or outgoing packets. The value can be one of the following:</p> <ul style="list-style-type: none"> • in • out <p>The V1 or V2 value specifies the RIP version (RIPv1 or RIPv2).</p> <p>The <ip-addr> indicates the network number in the denied updates.</p> <p>The <num> indicates how many packets matching the values above were dropped during the five-minute interval represented by the log entry.</p>
Warning	Temperature is over warning level.	The chassis temperature has risen above the warning level.

NIAP-CCEVS Certification

Some Brocade devices have passed the Common Criteria (CC) certification testing. This testing is sponsored by the National Information Assurance Partnership (NIAP) - Common Criteria Evaluation and Validation Scheme (CCEVS). For more information regarding the NIAP-CCEVS certification process refer to the following link: <http://www.niap-ccevs.org/>.

In an effort to maintain a proper level of security as it relates to access to network infrastructure resources, Brocade recommends that all Brocade hardware be installed within a secure location that is accessible by approved personnel only.

NIAP-CCEVS certified Brocade equipment and Ironware releases

The following Brocade devices have been NIAP-CCEVS certified. The following IronWare software release must be used to remain compliant with this certification:

TABLE 2 NIAP-CCEVS certified Brocade equipment and IronWare software releases

Brocade product	Brocade IronWare software version	Discussed in
NetIron XMR Family	3.8.00a	<i>NetIron Series Configuration Guide</i>
NetIron MLX Family	3.8.00a	<i>NetIron Series Configuration Guide</i>

Web-Management access to NIAP-CCEVS certified Brocade equipment

All Brocade networking devices that are to remain in compliancy with the NIAP-CCEVS certification must disable all remote access through the integrated Web management graphical user interface (GUI). In accordance with NIAP-CCEVS this functionality is considered a security risk and must be disabled.

Please refer to the *Brocade Configuration Guides* associated with each product listed in the table “[NIAP-CCEVS certified Brocade equipment and IronWare software releases](#)”, for detailed instructions on how to disable the Web Management Interface feature.

Local user password changes

Please note that if existing usernames and passwords have been configured on a Brocade Device with specific privilege levels (super-user, read-only, port-config), and if you attempt to change a user's password by executing the following syntax:

```
Brocade-Device(config)# user brcdreadonly password value
```

The privilege level of this particular user will be changed from its current value to "super-user". The “super-user” level username and password combination provides full access to the Brocade command line interface (CLI). To prevent this from occurring, use the following syntax:

```
Brocade-Device(config)# user fdryreadonly privilege value password value
```
